

DIET OF CAPE PETREL (*DAPTION CAPENSE*) AND SNOW PETREL (*PAGODROMA NIVEA*) AT SIGNY, SOUTH ORKNEY ISLANDS, ANTARCTICA

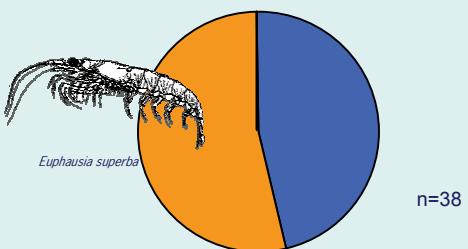

R.C. Fijn & J.A. van Franeker

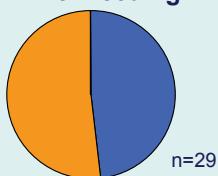

Food web knowledge is a prerequisite for adequate resource management in the Antarctic ecosystem. Diet composition of Cape and Snow Petrels was studied on Signy during the breeding season 2005-2006. Food samples were obtained by stomach flushing of both chick-feeding birds and non-breeding self-provisioning birds. Original prey mass was reconstructed from identifiable remains in the stomach samples.

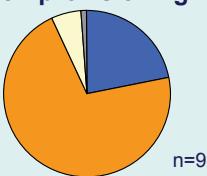

Cape Petrel

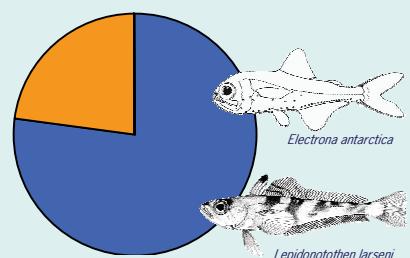

Chick-feeding

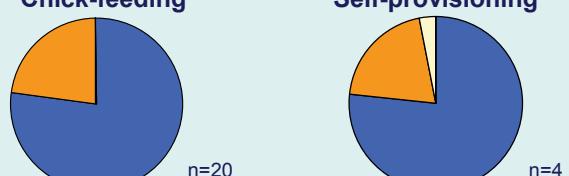

Self-provisioning

Snow Petrel

Self-provisioning

- Clear difference between self-provisioning and chick-feeding birds
- Self-provisioning birds have a significant higher fraction of squid in their diet

- High fraction of krill in Signy Snow Petrel diet compared to studies at other locations.
- Self-provisioning birds have a significant higher fraction of squid in their diet

Overall Conclusions:

1. Fish is an abundant prey item in both species which shows that even in a strongly krill dominated region, fish is an important part of the diet of Antarctic petrel species.
2. The differences in diet between chick-feeding and self-provisioning birds show the importance of studying **both** groups in overall dietary research.
