

# Trends in extreme weather impacts: attribution relevant to the Loss & Damage Mechanism

Laurens Bouwer and Reinhard Mechler

10 May 2016, Adaptation Futures, Rotterdam

# Introduction

- Uncertainty in damage and loss estimates
- · Analysis of historic losses: attribution
- · Projections
- · Role of vulnerability

**Deltares** 

## Loss and damage: what do we mean?

Loss and Damage definition (James et al. 2015 NCC):

- Residual damages (after adaptation)
- Actual and potential (risk)
- · Current impacts and future projections
- Human induced climate change
- Uncertainties in attribution larger for extremes than impacts from slow onset processes
- Vulnerability to which types of extremes? And relation to anthropogenic climate change

**Deltares**

3

# Domain of natural hazard risk assessment

- Focus on extreme (rare, high impact) events
- Loss and damage may also cover slow onset processes that lead to losses and damages
- · Traditionally dominated by engineering and economic sciences
- Strong role for statistics and probability theory
- Damage: to physical assets
- Loss: defined as loss of assets, or human lives
- Economic loss: monetised loss (often emphasis on physical assets)

**Deltares** 

12 mei 2016

### Disaster loss databases

Global databases of economic losses from natural hazards are:

- Fragmented:
  - Developing countries severely underrepresented (insurance)
- Incomplete:
  - · Not all hazards included droughts typically underrepresented
- · Biased:
  - More recent events better covered than events before ~1980
- Uncertain:
  - There is no common reporting convention on which losses should be included (private, public, direct or indirect)

# **Conclusions from IPCC**

#### IPCC SREX (2012):

"Increasing <u>exposure</u> of people and economic assets has been the <u>major cause</u> of long-term increases in economic losses from weather- and climate-related disasters (high confidence)."

Long-term trends in disaster losses adjusted for wealth and population increases <u>have not been attributed to climate change</u> (...)"

#### IPCC AR5 WG2 Chapter 18 (2014):

"(E)xtreme events have caused increasing impacts and economic losses, but there is only <u>low confidence in attribution</u> to climate change for these"

#### New research:

- Evidence for reductions in vulnerability for flood (Mechler & Bouwer 2015)
- Sub-proportional behaviour of exposure for cyclones (Estrada et al. 2015; Geiger et al. EGU 2016)

Deltares

12 mei 2016

# Projections of future risks

Wide variety of studies, very few that take a risk analysis approach

Reviews (Bouwer 2013 RA; IPCC AR5 WG2 Chapter 10)

Projected trend is upward, due to anthropogenic climate change

Many different hazards, including:

- Tropical cyclones
- Extra-tropical cyclones
- · River/pluvial flooding
- Hailstorm

- IAHS Panta Rhei WG: comparison of impacts from historic flood events: role of drivers including hazard, exposure and vulnerability

**Deltares** 

# Role of projected vulnerability

 Vulnerability decline will downscale future risks (Mechler & Bouwer 2015 CC):

7

### Some conclusions

- Using impact models it is possible to asses (economic) impacts from (changes in) extreme weather events, including risk potentials
- Very little/no evidence for increasing economic losses from extreme weather due to anthropogenic climate change
- This is the case for many hazard types, including river floods, and tropical and extra-tropical cyclones
- · Role of vulnerability changes still poorly understood
- Expected changes in exposure and vulnerability are very large, but still difficult to project
- Scope of Loss & Damage will need to consider the non-climatic dimension of future climate risks
