Chapter 1

General Introduction

Uncovering the molecular basis of growth, development, and adaptation is a major research area in plant science, with useful applications in plant breeding. Photosynthesis is an underused resource for plant breeding because of its physiological and molecular complexity as well as its complex relationship with yield. However, it is acknowledged to have great potential for crop improvement (Lawson et al., 2012; Long et al., 2015). The light-use efficiency of photosynthesis depends on the molecular, structural and physiological state of the plant (Eberhard et al., 2008; Zhu et al., 2008; Foyer et al., 2012). The physiological state depends on many environmental factors, of which the level of irradiance has a direct relation with photosynthesis light-use efficiency as it is the driving force for photosynthesis. Sudden increases in the level of irradiance can result in a situation in which the incoming light level exceeds the capacity for photosynthetic metabolism. Acclimation to increased irradiance is crucial for plant survival, as excess incoming light levels lead to damaged photosystems and the production of reactive oxygen species (ROS). The acclimation response of photosynthesis appears to reduce the formation of ROS, especially under excess irradiance levels (Scheibe et al., 2005; Suzuki et al., 2012).

This thesis describes a study into natural genetic variation for the acclimation response of photosynthetic light use efficiency to increased growth irradiance. By identifying and characterizing genes for which different alleles affect photosynthesis responses, I could reveal some of the regulatory and physiological processes underlying natural variation for photosynthetic acclimation to a step increase in irradiance

Photosynthesis

Central to this thesis is the understanding of photosynthesis at the molecular level. When trying to identify genes, one needs to realize each gene encodes for one protein. A protein is a biological macro-molecule, consisting of a chain of amino acids folded in a specific three-dimensional structure that determines its pattern of activity. The sequence of amino acids is encoded for by the gene and one small change in the gene's DNA sequence can result in a different amino acid, which can result in different structural properties of the protein, which can result in a different biological functionality.

The process of photosynthesis has been studied for long time, with its first discovery by Jan van Helmont in the 17th century, who discovered that the mass of a growing plant came from water and carbon dioxide (and not from soil). In the next century, Jan

Ingenhousz discovered this process was powered by sunlight. Not long after that, it was discovered that both CO_2 and water are the substrates for a plant to form biomass and O_2 under the influence of light energy (Hill, 2012).

Photosynthesis is a complex process both at the physiological as well as the molecular level, involving many steps. These include the light reactions: the harvest of light energy, the transfer of excitation energy, the energy conversion, the electron transfer from water to NADP^+ , the oxygen evolution, and the ATP generation; and the dark reactions: the Calvin cycle that fixes CO_2 to assimilate carbohydrates, catalysed by the enzyme ribulose-1,5-bisphosphate carboxylase/oxygenase (Rubisco) (Fig. 1). Proteins and cofactors, coded for by genes, execute all of these steps. Some of these genes are encoded in the nuclear genome, and some in the chloroplast genome, requiring complex cross talk between nucleus and chloroplast. The work described in this thesis is focussed the identification and characterization of genes involved in photosynthesis responses to increased light levels extending over several days, which is directly related to the primary processes of photosynthesis (light harvesting and energy conversion), the energy transduction machinery, and the metabolic processes of photosynthesis. The applied genetic methods exclusively targeted the nuclear encoded genes.

Figure 1. The light and dark reactions (Calvin Cycle) of photosynthesis.

Picture from Pearson Education, 2012.

Photosynthesis occurs in the chloroplasts, where chlorophyll molecules divided over two different photosystems harvest the incoming light. The photosystems are embedded in

the thylakoid membranes, which are specialized structures laying inside the chloroplast. Photosystem II (also known as PSII, Psb, and P600) absorbs light up to 600 nm wavelength and contains both chlorophyll a and chlorophyll b. Photosystem I (also known as PSI, Psa, and P700), absorbs light up to 700 nm wavelength and contains only chlorophyll a. At the molecular level, both photosystems are connected to light harvesting complexes (LHCI for PSI and LHCII for PSII). PSII is associated with the oxygen-evolving complex (also known as the water-splitting complex), which donates an electron coming from a water-molecule each time PSII is excited with light (Fig 2). This is the first reaction of the light reactions, using the high-energy state of the chlorophyll molecules associated with PSII. This energy then enters an electron transport chain involving plastoquinone (PQ), cytochrome *b6/f* (Cyt *b6/f*), and plastocyanin (PC), whereby the high energy molecule ATP is produced that is later needed in the dark reactions of photosynthesis (Fig. 2). The ATP is formed through an ATPase acting as a proton-pump, pumping the H^+ coming from the water molecules through the thylakoid membranes resulting in proton motive force (Fig. 2). At the end of the electron transport chain, the electron has lost its energy, and is donated to PSI. The excited electrons from PSI are then donated to ferredoxin (Fd), a soluble protein that facilitates reduction of $NADP^+$ to NADPH, a high-energy molecule needed for the dark reactions of photosynthesis (Fig. 2).

Sensing and responding to excess light

Light is the driving force for photosynthesis, and the relationship between light and photosynthesis is complex. Light is essential for photosynthesis, but absorbed light exceeding the photosynthetic capacity of a plant gives rise to reactive intermediates and by-products that can damage the photosynthetic machinery (Powles, 1984; Asada, 2006). Protection from these damaging processes, while at the same time permitting high photosynthetic rates under high light conditions, seems to be the driving force behind the evolution of many of the regulatory processes of photosynthesis. This thesis describes discoveries on the genetic variation apparent for these regulatory processes in natural populations, explaining part of the photosynthetic acclimation process. This requires understanding of the physiological and molecular regulatory processes occurring in the plant cell when it experiences excess light stress. Excess light can arise simply when the amount of absorbed light exceeds the plant's photosynthetic capacity, but can also result from decreases in photosynthesis rates as result of chilling or water stress. This thesis only focusses on the first situation.

Plants have evolved several mechanisms for sensing increases in absorbed irradiance levels (Li et al., 2009); they sense it using several classes of photoreceptors, and they sense it through biochemical and metabolic signals. The photoreceptors involved in excess light response are: phototropins, phytochromes and cryptochromes. The biochemical and metabolic signals come from internal redox and internal pH levels (Li et al., 2009).

The photoreceptor phototropin mediates avoidance response of chloroplast, which makes these move to the sides of a plant cell to avoid excess light absorption (Kasahara et al., 2002). Changes in light quantity can come about with changes in light quality, especially when a plant is moved from a shaded environment to an exposed environment. When plants shade each other, this causes a change in the light spectrum, as the chlorophyll of the upper plants absorbs some wavelengths. Only the light that is outside the spectral range and capacity for the upper plants is transmitted to the lower plants. The changes in spectral composition of the light when a plant is moved from a shaded to exposed environment is sensed by the phytochrome photoreceptor. Phytochrome mainly influences responses unrelated to photosynthesis, such as stem- and leaf elongation, flowering time, and seed maturation (Schepens et al., 2004). The cryptochrome photoreceptor is shown to regulate a large number of genes in response to increased light, that at the end of the signalling cascade lead to formation of flavonoids and

anthocyanins that protect photosynthesis tissue from high light damage by absorbing the high energy containing blue-green and ultraviolet light, significantly reducing the amount of ROS produced (Kleine et al., 2007).

Two major biochemical signals indicate excess light, a pH-change within the chloroplast occurring within milliseconds after the induction of the stress (proton gradient dependent regulation) and a redox change via changes in thioredoxin levels and oxidized/reduced plastoquinone ratios as well as through a build-up of ROS (redox-dependent regulation). The pH-change, occurring over the thylakoid membranes, results from a decrease in the ATPase proton-pump. The extra electrons coming from the increased irradiance level will go to other acceptors than the electron transport chain, such as oxygen (producing ROS) or thioredoxin, resulting in decreased lumen pH. This is sensed by the protein PsbS (Li et al., 2004), which then activates the energy-dependent part of the photoprotection response (non-photochemical quenching, NPQ), (Demmig-Adams and Adams, 1992). NPQ is a mechanism involving the fast dissipation of the excess excitation energy as heat. It involves several molecular mechanisms, which are energy-dependent quenching (qE), quenching associated with state transitions (qT), and photoinhibitory quenching (qI), (Horton and Hague, 1988). The fastest response is qE, which is the only NPQ mechanism initiated by the protein PsbS, involves dissipating the excess energy through the xanthophyll cycle, resulting in the formation of zeaxanthin. Protonation of PsbS and binding of zeaxanthin to PSII produces conformational changes in the photosystems that result in increases in the efficient heat dissipation of the excess energy (Sylak-Glassman et al., 2014). The second NPQ response is qT, where phosphorylation of PSII associated light-harvesting complexes results in a decrease in the cross section of PSII with LHCII and an increase in that of PSI and LHCII, thereby adjusting the relative excitation energy distribution between PSII and PSI (Tikkanen et al., 2010). The last NPQ response is qI, resulting from photoinhibition of photochemistry, increasing the dissipation of excitation energy as heat, by breaking down photosynthetic proteins. NPQ is a photoprotection response occurring mainly around PSII. PSI has evolved an alternative protective mechanism for excess light, resulting in cyclic electron flow around PSI (Munekage et al., 2004). In cyclic electron flow, electrons can be recycled from either reduced ferredoxin or NADPH to plastoquinone, and subsequently to the cytochrome *b₆f* complex. This generates a renewed proton motive force for ATP production, decreasing lumen pH without the accumulation of ROS, thus protecting the photosystem proteins from damage and keeping up the supply of ATP and NADPH enabling increased photosynthesis rates. A third alternative for the dissipation of excess electrons is the donation to O₂, forming H₂O₂ and ultimately water. This is known as the water-water cycle, because the initial

reaction in photosynthesis is the splitting of water, donating electrons to PSII for excitation. It is also known as the Mehler reaction, named after its first discoverer (Mehler and Brown, 1952). Extra advantage of the water-water cycle is it also scavenges ROS, as it binds superoxide formed by the reduction of O₂ (Asada, 1999).

When the excess light persists after a few hours when photoprotection has finished, the plant will start altering its photosynthetic proteome, via what is known as photosynthetic acclimation (Walters, 2005). This response is initiated by the photoreceptor cryptochrome (the CRY1 protein), as well as by several heat-shock proteins and heat shock transcription factors (Rossel et al., 2002; Kleine et al., 2007). Ultimately, photosynthetic acclimation will provoke changes in the cellular composition in terms of their organisation of the photosystems, proteins, pigments, lipids, and other cofactors involved in electron transport and ROS metabolism (Bailey et al., 2004; Walters, 2005). Regarding the organisation of the photosystems, in response to high irradiance PSII acclimates by decreasing its antenna size via a decrease the amount of LHCII proteins associated with the PSII supercomplex, analogous to the short-term qT response (Kouřil et al., 2013). The ratio of LHCI to PSI is not altered, but the antenna size of PSI decreases with increasing irradiance due to a decreased association of LHCII with PSI (Ballottari et al., 2007; Wientjes et al., 2013). All the changes during photosynthetic acclimation are the result of signal-induced changes in gene expression, in a tight co-ordinated regulation between nuclear and chloroplast genes. At the time when I started the project of which the results are described in this thesis, molecular understanding of photosynthetic acclimation lagged behind the understanding of photosynthesis itself as well as behind the molecular understanding of photoprotection.

Phenotyping photosynthesis

Photosynthesis is about taking up CO₂ for fixation into carbohydrates, and releasing back O₂ into the atmosphere. Therefore, its most direct measurement for photosynthesis efficiency is through gas exchange analysis (Von Caemmerer and Farquhar, 1981; Long et al., 1996b; Johnson and Murchie, 2011). Infra-red sensors for gas analysis (IRGA) are most common for CO₂ measurement and are based on an infrared emitter-photodetector of which the light beam is used to measure the concentration of gas molecules in the air of a leaf chamber (Sesták et al., 1971). In order to measure variation for photosynthesis efficiency among natural populations, the IRGA method is very laborious as for every plant at least one leaf (normally it is leaves that are measured rather than shoots or larger

parts of plants) has to be enclosed inside a leaf chamber each time photosynthesis is measured.

Besides gas-exchange, photosynthesis is about efficiently using the light energy that is absorbed by the plant. Once a photon is absorbed by the plant, it can have three fates: used for photosynthesis (photochemistry), dissipated as heat (a process facilitated by photoprotection), or re-emitted as chlorophyll fluorescence (Butler, 1978). Chlorophyll fluorescence is the light re-emitted by chlorophyll molecules during return from excited to non-excited states, and is the only one of the three fates that can easily be measured. Using a smart design of repeatedly measuring chlorophyll fluorescence in open and closed photosystems, calculations can be made of the amount of light energy going into photochemistry, and thus the photosynthetic light use efficiency, Φ_{PSII} (Baker, 2008). Because chlorophyll fluorescence can be detected using a camera, it is non-destructive and it can easily handle many plants by either automatically moving each plant to the camera, or automatically moving the camera to each plant (Harbinson et al., 2012; Flood et al., 2016).

From phenotype to genotype

The area within biology that tries to genetically explain phenotypes that vary continuously, such as photosynthetic light use efficiency, is called quantitative genetics, whereby the genetic loci explaining the phenotypes are called quantitative trait loci (QTLs), (Alonso-Blanco et al., 2009; Alonso-Blanco and Méndez-Vigo, 2014). To perform quantitative genetics in plants, *Arabidopsis thaliana* is the model species of choice, because of its well-described genetics, its wide availability of genotyped natural accessions, and the ability to exploit it in genome wide association studies (GWAS), (Atwell et al., 2010; Bergelson and Roux, 2010; Ogura and Busch, 2015). Genome-wide association studies (GWAS) analyse natural variation in populations consisting of a large number of natural isogenic lines collected from nature, called natural accessions in case of *Arabidopsis thaliana* (Arabidopsis). The accessions are collected worldwide in the native range of Arabidopsis, and as such have genetically adapted to different ecological conditions over thousands of years. In order to genetically map quantitative traits to the genome, GWAS take advantage of the recombination events that have accumulated over all those generations resulting in a high mapping resolution (Bergelson and Roux, 2010). An important aspect to consider when performing GWAS is Linkage Disequilibrium (LD), which is the non-random association of alleles at different loci, affecting the number of

recombination events occurring through time (Kim et al., 2007). When LD is only over short lengths in the genome, it requires a very high density of genotyping to find causal loci for a phenotypic trait in GWAS. Over the past years, GWAS have proven to be successful in *Arabidopsis* for identifying novel genes underlying the natural variation in several physiological (Atwell et al., 2010; Chao et al., 2012), morphological (Filaout and Maloof, 2012), cellular (Meijón et al., 2014; Verslues et al., 2014), and defence-related traits (Horton et al., 2014). The interpretation of association peaks in GWAS is not straightforward as population structure can lead to the occurrence of false positive associations, and the presence of causal alleles with low allele frequency or the presence of multiple alleles having the same phenotype can lead to hidden heritability (Korte and Farlow, 2013). One factor leading to hidden heritability is an epistatic interaction between two (or more) genes, where the allelic effect of one gene is depending on the allelic effect of another gene (Korte and Farlow, 2013).

A more traditional method to link phenotypic variation to genetics is to do family mapping (Lander and Botstein, 1989). For this, two different accessions are crossed, the heterozygous plant that arises is self-fertilized, and the segregating offspring are phenotyped for the trait of interest, and genotyped for enough molecular markers to cover the genome. In this approach, different numbers of accessions can be (inter-) crossed to vary the amount of genetic variation, and different generations of offspring can be chosen for analysis to vary the level of heterozygosity. While family mapping provides the mapping power that is lacking in GWAS, it has a very low resolution because it depends upon the limited number of recombination events that have occurred in one (or a few) generation(s). The combination of GWAS and family mapping has proven to be a successful strategy in unravelling complex plant genetics (Motte et al., 2014).

Resolving QTLs to the gene level for any biological process being studied will help the physiological and molecular understanding of that process. To study natural genetic variation for any trait, first a survey must be performed on the extent of variation present among different accessions before proceeding to the genetic analysis, as described in chapter 2 of this thesis for photosynthesis efficiency responses to increased irradiance in *Arabidopsis*.

Outline of thesis

In this thesis, I describe a study of natural genetic variation for photosynthesis responses to increased growth irradiance. This work was carried out within the research programme of BioSolar Cells, co-financed by the Dutch Ministry of Economic Affairs. The aim of Biosolar Cells is to optimize the photosynthesis process in plants, algae and bacteria, and to develop artificial leaves that combine biological and artificial components (www.biosolarcells.nl).

Plants are known to be able to acclimate their photosynthesis to the level of irradiance. **Chapter 2** describes which light environment reveals most natural variation and for which photosynthetic parameter this is. It shows different Arabidopsis accessions display different photosynthetic responses to various light environments, well relatable to genetic differences. A candidate gene list for the direct response to increased growth irradiance was revealed.

Acclimation of photosynthesis to changing light environment is a dynamic trait, for which at different time points, different genes are causal. **Chapter 3** describes the dynamics of the QTLs underlying photosynthetic acclimation to increased growth irradiance. This chapter shows it is possible to simplify the complexity of photosynthetic physiology as well as the genetic analysis in such way to confirm the causal underlying genes. This was confirmed for the *YS1* gene, a gene encoding a Pentatricopeptide-Repeat (PPR) protein involved in RNA editing of plastid-encoded genes essential for photosystems I and II.

Genetic variation for any trait can be on the transcriptional level or on the functional level (quantity versus quality). **Chapter 4** analyses the transcriptional response of three Arabidopsis accessions with distinct photosynthesis responses to increased growth irradiance. The existence of a gene activation pathway leading to the process of membrane lipid transformation was shown, whose involvement in photosynthetic acclimation is explained by the replacement of phospholipids by galactolipids for releasing extra orthophosphate (Pi) needed for photosynthetic structures and creating a charge balance to the photosynthetic membranes that is overcharged as a result of the excess light. Accession-specific differences in activation of this gene activation pathway could be associated with variation in photosynthesis efficiency response to increased irradiance.

Chapter 5 describes how genome wide association mapping (GWAS) and family mapping combine to reveal genetic epistatic interactions underlying photosynthetic

acclimation to increased growth irradiance. This chapter shows an epistatic relation between two genes, *PHOSPHATIDIC ACID PHOSPHOHYDROLASE 2 (PAH2)* and *ASPARAGINE SYNTHETASE 2 (ASN2)*. Strong indications are given for the involvement of combinations of specific *PAH2* and *ASN2* natural alleles in keeping high photosynthesis efficiencies in response to increased irradiance.

It In **Chapter 6**, the results of the preceding chapters are discussed in the context of current research on quantitative genetics and photosynthetic physiology.

Chapter 2

Natural genetic variation for acclimation of photosynthetic light use efficiency to growth irradiance in *Arabidopsis thaliana*

ABSTRACT

Plants are known to be able to acclimate their photosynthesis to the level of irradiance. Here we present the analysis of natural genetic variation for photosynthetic light use efficiency (Φ_{PSII}) in response to five light environments among 12 genetically diverse *Arabidopsis thaliana* accessions. We measured acclimation of Φ_{PSII} to constant growth irradiances of four different levels (100, 200, 400, and 600 $\mu\text{mol m}^{-2} \text{s}^{-1}$) by imaging chlorophyll fluorescence after 24 days of growth, and compared these results to acclimation of Φ_{PSII} to a step-wise change in irradiance where the growth irradiance was increased from 100 to 600 $\mu\text{mol m}^{-2} \text{s}^{-1}$ after 24 days of growth. Genotypic variation for Φ_{PSII} is shown by calculating heritability for short-term Φ_{PSII} response to different irradiance levels, as well as for the relation of Φ_{PSII} measured at light saturation (a measure of photosynthetic capacity) to growth irradiance level, and for the kinetics of the response to a step-wise increase in irradiance from 100 to 600 $\mu\text{mol m}^{-2} \text{s}^{-1}$. A genome-wide association study for Φ_{PSII} measured one hour after a step-wise increase in irradiance identified several new candidate genes controlling this trait. In conclusion, the different photosynthetic responses to a changing light environment displayed by different *Arabidopsis* accessions are due to genetic differences, and we have identified candidate genes for the photosynthetic response to an irradiance change. The genetic variation for photosynthetic acclimation to irradiance found in this study will allow future identification and analysis of the causal genes for the regulation of Φ_{PSII} in plants.

Abbreviations:

PSI – photosystem I; PSII – photosystem II; LHC – light harvesting complex; F_o – minimum fluorescence yield in dark-adapted state; F_m – maximum fluorescence yield in dark-adapted state; F_m' – maximum fluorescence yield in light-adapted state; F_v/F_m – maximum photosynthetic light use efficiency of PSII in dark-adapted state; Φ_{PSII} – operating photosynthetic light use efficiency of PSII in light-adapted state; rETR – relative electron transport rate; NPQ – non-photochemical quenching; q_p – co-efficient of photochemical quenching of chlorophyll fluorescence (PSII efficiency factor); F_v'/F_m' – photosynthetic light use efficiency of the open PSII reaction centres in light-adapted state

INTRODUCTION

Light is the driving force for photosynthesis and the relation between light and photosynthesis is complex; light is essential for photosynthesis but absorbed light naturally gives rise to reactive intermediates and by-products that can damage the photosynthetic machinery (Powles, 1984; Asada, 2006). Even at low irradiances these damaging reactions occur and they increase with increasing irradiance as photosynthesis becomes increasingly light-saturated. Protection from these damaging processes, while at the same time permitting high photosynthetic rates under high light conditions and a high light use efficiency under low light conditions, seems to be the driving force behind evolution of many of the regulatory processes of photosynthesis.

Managing the fate of absorbed light energy is regulated within a plant at the level of the chloroplast membranes. Chloroplast membranes are highly organised; the total amount of photosystems in a chloroplast, the amount of photosystem I (PSI) in relation to photosystem II (PSII), and within each photosystem the amount of light harvesting complexes (LHCs) in relation to the amount of reaction centres, are tightly organised in response to the prevailing light condition around the leaf (Dekker and Boekema, 2005; Kouřil et al., 2012; Tikkanen et al., 2012; Kouřil et al., 2013). A high growth irradiance will lead to relatively more photosystem-core protein complexes, electron transport complexes, ATP synthase and enzymes in the Calvin-Benson cycle, whereas low growth irradiances will lead to relatively more light harvesting complexes and stacking of the thylakoid membranes (Bailey et al., 2001).

With increasing irradiance, the rate of excitation of PSII and PSI exceeds the capacity of photosynthetic electron transport or metabolic capacity, resulting in excess irradiance. In the short-term this provokes a physiological, regulatory response, while in the longer term a sufficiently large excess irradiance will often result in alterations in the chloroplast proteome. Both the short-term and long-term responses have limits to their action (Foyer et al., 2012; Tikkanen et al., 2012). In the short-term, excess irradiance imposes a strain on the capacity to protect the photosystems from damage (photoprotection) (Demmig-Adams and Adams, 1992). PSII is particularly susceptible to photodamage and has evolved an active regulatory process to reduce the extent of damage combined with an active repair system to replace damaged PSII reaction centres. As a first line of defence, PSII to a certain extent is able to dissipate the excess irradiance as heat via regulated non-photochemical quenching mechanisms (NPQ) reducing the rate of reaction centre damage (Rabinowitch, 1951). This process is initiated within seconds after an increase in

light intensity (Muller et al., 2001). The mechanism of NPQ in plants has been intensively studied, with most focus on the role of lumen pH dependent, or energy-dependent, dissipation of excess light (also known as qE, (Demmig et al., 1987)) via a mechanism that involves psbS and the xanthophyll cycle, one of the major short-term regulatory responses to excess irradiance.

The long-term response of plants to excess irradiance occurs over the time scale of hours or days and results in acclimation to the excess irradiance environment (Walters, 2005). This leads to increased capacities for electron and proton transport, coupled with increased photosynthetic metabolic capacity, often combined with alterations in organisation of the photosystems. These changes in capacity are due to changes in the amounts of soluble enzymes of photosynthesis, in electron transport components and pathways, and in pigment-protein complexes (Murchie and Niyogi, 2011). Regarding the photosystem subunit stoichiometry, PSII in response to high irradiance decreases its antenna size by decreasing the amount of LHCII proteins associated with the PSII supercomplex (Kouřil et al., 2013). Though the ratio of LHCI to PSI is not altered by irradiance, the antenna size of PSI decreases with increasing irradiance due to a decreased association of LHCII with PSI (Ballottari et al., 2007; Wientjes et al., 2013) (ie decreases in the amount of LHCII seems to alter the antenna size of both photosystems). In addition to this long-term adjustment of PSI cross-section, a short-term adjustment of the relative cross-sections of PSII and PSI can be brought about by state-transitions, driven by phosphorylation of LHCII, with phosphorylation being associated with a decrease in the cross-section of PSII and an increase in that of PSI (Allen, 1992; Tikkanen et al., 2010).

In the event that the sum of the short and long-term regulatory responses are insufficient, then more persistent damage to the photosynthetic apparatus (photoinhibition), especially to PSII, results. Damage to PSII, which is conveniently measured as a reduction of the F_v/F_m parameter derived from chlorophyll fluorescence measurements (Baker, 2008), is commonly used as an indicator of decreased photosynthetic performance arising from excess irradiance, though other parameters, such as decreased leaf chlorophyll content, are also used (Björkman and Demmig, 1987). The irradiance at which this damage will become apparent is difficult to predict.

Natural genetic variation in plant photosynthesis is a valuable resource (Flood et al., 2011). Naturally occurring variation in the photosynthetic acclimation response to high light has been observed in different plant species, with different studies using different

light regimes and focussing on different acclimation responses (Sims and Pearcy, 1993; Valladares et al., 1997; Balaguer et al., 2001; Leakey et al., 2003; Portes et al., 2008). However, research combining different light regimes and looking at the acclimation responses of different aspects of photosynthesis in different genotypes in one experiment is lacking. *Arabidopsis thaliana* (*Arabidopsis*) is the model species for plant genetic research, a choice that was motivated partly because of the considerable variation found in this species for many traits. The number and variety of natural genotypes of *Arabidopsis* make it increasingly valuable as physiological model (Alonso-Blanco et al., 2009). The variability of photosynthetic acclimation in naturally occurring genotypes of *Arabidopsis* has been investigated for light-use efficiency in one growth environment (El-Lithy et al., 2005), for NPQ responses to high light (Jung and Niyogi, 2009), for photosynthetic capacity in response to high light (Athanasidou et al., 2010), and for the response to short-term light flecks (Alter et al., 2012). To explore the phenotypic plasticity and genetic variation within *Arabidopsis thaliana* we have investigated the variability of the acclimation of multiple photosynthesis parameters to four constant growth irradiances and to a step-wise increase in the growth irradiance among 12 genotypically diverse accessions. To assess what part of the variability is due to genetic variation, we have calculated trait heritabilities, which are a measure of the extent of trait variation that is due to genetic variation. The possible genetic basis for trait variation can be determined using genome-wide association study (GWAS), in which genetic loci associated with a trait are identified by correlating genetic variation with trait variation (Atwell et al., 2010). To perform GWAS, there must be a description of genetic variation and the trait must be variable and heritable. It requires a large number of genotypes, so we used a population of 344 diverse *Arabidopsis* accessions which all had been genotyped for ~215 000 single nucleotide polymorphisms (SNPs) (Kim et al., 2007; Li et al., 2010). Importantly, because the genotypic description is restricted to the nuclear genome, any phenotypic variation arising from variation in cytoplasmic genomes cannot be associated with those genomes and will be a source of noise in the analysis. A GWAS for Φ_{PSII} measured one hour after a step-wise change in irradiance was used to identify genomic regions that are associated with the response of photosynthesis to step-wise increase in irradiance. These results highlight the genetic variation and physiological adaptability (or lack of it) of photosynthesis in *Arabidopsis*. The presence or absence of variability is of particular importance in relation to both the evolution of the photosynthetic properties of *Arabidopsis* and the future identification of those genetic factors that give rise to the photosynthetic phenotype.

MATERIALS AND METHODS

Plant material and growth conditions

The measurements described here can be divided into genome-wide association study (GWAS) and non-GWAS measurements. As the non-GWAS measurements were used as a pilot for the GWAS, many of the methods and genotypes used are common to both the non-GWAS and GWAS measurements.

The non-GWAS measurements were made on twelve genotypically diverse accessions of *Arabidopsis* which were used throughout the experiments in this study (Table I), grown in 3 replications. All these accessions are part of a core set of 360 natural accessions, which represents the global genetic diversity in *Arabidopsis* (<http://www.naturalvariation.org/hapmap> (Li et al., 2010)). For the GWAS, we used 344 accessions of the set of 360 accessions; included in the set of 344 accessions were all of the accessions used in the non-GWAS study. The 16 accessions that were not used were lines CS28051, CS28108, CS28808, CS28631, CS76086, CS76104, CS76110, CS76112, CS76118, CS76121, CS76138, CS76196, CS76212, CS76254, CS76257, and CS76302.

Table I. Origin of the twelve accessions of *Arabidopsis* used in this study

| Accession | Full name | Latitude | Longitude | Origin |
|-----------|-------------------------|----------|-----------|----------------|
| Bor-4 | Borky | 49.4 | 16.2 | Czech Republic |
| Bur-0 | Burren | 53 | -9 | Ireland |
| C24 | C24 | 41.2 | -8.4 | Portugal |
| Can-0 | Canary Islands | 29.2 | -13.5 | Spain |
| Col-0 | Columbia | - | - | unknown |
| Cvi-0 | Cape Verde Islands | 15.1 | -23.6 | Cape Verde |
| Est-1 | Estonia | 58.3 | 25.3 | Estonia |
| Ler-1 | Landsberg <i>erecta</i> | 52.7 | 15.2 | Poland |
| NFA-8 | NFA | 51.4 | -0.6 | United Kingdom |
| Sha | Shahdara | 38.3 | 68.5 | Tajikistan |
| Tsu-0 | Tsushima | 34.4 | 136.3 | Japan |
| Van-0 | Vancouver | 49.3 | -123 | Canada |

For both GWAS and non-GWAS experiments seeds were pre-sown on filter paper in petri dishes wetted with filled with 0.5 mL demineralised water, and placed in the dark at 4°C for 4 days to stratify. Once stratified, the seeds were planted in a hydroponic cultivation system based on rockwool blocks (Grodan Rockwool Group, 40 X 40 X 40 mm in size). The blocks were positioned and secured using a frame (Fig. 1) of consisting of a baseplate made from a sheet of perforated stainless steel, a second PVC frame that was held 15 mm above the stainless steel base and into which the blocks were placed, and a black non-reflective foamed PVC cover-sheet drilled with countersunk holes 60 mm apart and 3 mm diameter that were positioned over the centres of the blocks. The seeds were placed on the rockwool surface exposed in these holes and the plants then grew up through the holes with the leaves spreading across the surface of the upper, black PVC sheet. The three layers of the growing system were secured by stainless steel screws and spacers and placed in a basin to which nutrient solution could be added. The baseplate was supported 5 mm above the floor of the basin, allowing nutrient solution to pass freely and uniformly under the growing frame and circulate through the frame via the holes in the perforated metal baseplate and the 10 mm spaces between the blocks. The black plastic upper plate prevented the growth of algae on the rockwool blocks and offered a good background for imaging of the plants.

For the smaller scale non-GWAS experiments the growing frame was 180 X 180 mm in size (Fig. 1) and could hold 9 individual rockwool blocks in a 3 x 3 array. Three seeds were sown per accession and the total of 36 seeds were randomized over four growing systems, with the limitation that two seeds of the same accession were never planted in the same growing system. For the GWAS experiment the growing frame was 390 x 85 cm and could hold 720 rockwool blocks in a 60 x 12 array. Two of these 60 x 12 growing systems, each in a separate basin, were combined to potentially grow a total of 1440 (allowing for four replicates of 360 genotypes) plants for the GWAS. Each growing frame was notionally sub-divided in two blocks, giving a total of four growing blocks. Four seeds were sown per accession in the GWAS experiment, and each set of 344 seeds was randomized over each of the four blocks.

For both GWAS and non-GWAS experiments plants were grown hydroponically using a nutrient solution developed for Arabidopsis (pH 7; EC 1.4 mS/cm) consisting of 1.7 mmol NH_4^+ , 4.5 mmol K^+ , 0.4 mmol Na^+ , 2.3 mmol Ca^{2+} , 1.5 mmol Mg^{2+} , 4.4 NO_3^- , 0.2 mmol Cl^- , 3.5 mmol SO_4^{2-} , 0.6 mmol HCO_3^- , 1.12 mmol PO_4^{3-} , 0.23 mmol SiO_3^{2-} , 21 $\mu\text{mol Fe}^{2+}$ (chelated using 3% diethylene triaminopentaacetic acid), 3.4 $\mu\text{mol Mn}^{2+}$, 4.7 $\mu\text{mol Zn}^{2+}$,

14 $\mu\text{mol BO}_3^{3-}$, 6.9 $\mu\text{mol Cu}^{2+}$, and $<0.1 \text{ MoO}_4^{4-}$, which was added to the basins containing the growing frames for 5 minutes 3 times a week.

For the non-GWAS experiments plants were grown at either constant irradiances of 100, 200, 400 or 600 $\mu\text{mol m}^{-2} \text{ s}^{-1}$ (Philips fluorescent tubes, MASTER TL5 HO, 80W), or the irradiance was increased from 100 $\mu\text{mol m}^{-2} \text{ s}^{-1}$ to 600 $\mu\text{mol m}^{-2} \text{ s}^{-1}$ at noon, 24 days after sowing on rockwool. In all cases the photoperiod was 10h/14h day/night cycle, temperature was 20/18°C (day/night), relative humidity was 70% and CO_2 levels were ambient. Following the step increase in irradiance the photosynthetic acclimation response was measured over five days, by measuring light response curves once a day in the morning 30 minutes after light onset. Other conditions were kept similar, although an increase of leaf temperature due to energy absorbed by the black cover needed for imaging could not be prevented. The highest irradiance we used in this study was well within the adaptive range of the accessions used so even the highest irradiance used was non-stressful insofar that it provoked no significant sign of light stress (eg a decrease in the dark-adapted F_v/F_m or anthocyanin formation). At the end of the acclimation period to increased growth irradiance in this second experiment, when Φ_{PSII} had stabilized, light response curves were compared to curves of plants grown at either a constant low (100 $\mu\text{mol m}^{-2} \text{ s}^{-1}$) or high (600 $\mu\text{mol m}^{-2} \text{ s}^{-1}$) growth irradiance. Plants were measured using chlorophyll fluorescence imaging for the first time at 30 minutes after light onset on the 24th day after sowing on rockwool. Depending on the experiment, this imaging was continued daily at the same time until plants began to overlap.

For the GWAS experiments plants were grown at constant irradiance of 100 $\mu\text{mol m}^{-2} \text{ s}^{-1}$ (Philips fluorescent tubes, MASTER TL5 HO, 80W). The irradiance was increased to 550 $\mu\text{mol m}^{-2} \text{ s}^{-1}$ on day 25 after sowing, at the onset of irradiance. In all cases the photoperiod was 10h/14h day/night cycle, temperature was 20/18°C (day/night), relative humidity was 70% and CO_2 levels were ambient. The plants were imaged one hour after light onset on day 24 ('measurement before the increase in irradiance'), as well as one hour after light onset on day 25 ('measurement after the increase in irradiance').

Figure 1. Growing system for Arabidopsis used in this study;

(A) top view showing non-reflective cover with small holes covering rock wool blocks on which Arabidopsis is germinated and grown; (B) when the non-reflective cover is removed, the rock wool block can be placed in 4 x 4 cm square holes, on a stainless steel grid, which is supported by short pins allowing nutrient solution to spread evenly underneath the rock wool blocks.

Chlorophyll a fluorescence imaging and analysis

For the non-GWAS experiments chlorophyll a fluorescence was measured using an imaging fluorimeter (Open FluorCam, P.S.I., Brno, Czech Republic, <http://www.psi.cz>), driven by the Fluorcam software package (FluorCam7). Fluorescence was detected by a camera of which the electronic shutter time and sensitivity were adapted to the irradiance being used. Measurements of the dark-adapted F_o and F_m were measured after 20 minutes of dark-adaptation. Images of the dark-adapted F_o were measured using non-actinic measuring flashes provided by light emitting diodes (LEDs). Next, a 1-s duration pulse of saturating light ($6500 \mu\text{mol m}^{-2} \text{s}^{-1}$) generated by the same and other LED-panels was given produce the maximum fluorescence level in the dark, F_m . An image of F_v/F_m was then calculated. To measure the irradiance response of parameters describing the operation and regulation of PSII the plants were illuminated with a series of increasing actinic irradiances (100, 225, 450, 700, and $1150 \mu\text{mol m}^{-2} \text{s}^{-1}$). Each irradiance was applied for 15 minutes after which the F_t (steady-state fluorescence yield) and F_m' yield were measured. Pilot experiments showed that using these irradiances 15 minutes was sufficient time to allow F_t and F_m' to stabilise after each irradiance increase. The F_m' fluorescence yield was measured during a 1-s duration pulse of saturating light ($6500 \mu\text{mol m}^{-2} \text{s}^{-1}$). Values for F_o , F_m , F_t and F_m' in the images were averaged over all pixels per plant; derived values for Φ_{PSII} , F_v/F_m , NPQ, q_p , rETR, F_o' , and F_v'/F_m' were calculated using these averages of F_o , F_m and F_m' (Oxborough and Baker, 1997; Baker, 2008).

For the imaging of the 344 accessions used for GWAS, we used a laboratory built high-throughput chlorophyll fluorescence imager. This system imaged plants in groups of 12 (a

3 X 4 array). Chlorophyll fluorescence was measured at 730 nm and excited using radiation from Phlatlight leds (Luminus, Billerica, Massachusetts, USA) (peak emission wavelength 624 nm). Φ_{PSII} was imaged at growth-room irradiance, and the irradiances supplied by the growth room (produced by fluorescent tubes) and the imager (produced by LEDs) were matched by comparing Φ_{PSII} (measured using a chlorophyll fluorimeter (MiniPam, Walz, Effeltrich, Germany)) in leaves under the growth room irradiance and the imager irradiance. The matching of the irradiances provided by the growth-room lights and the actinic irradiance of the imager meant that there was only minor disturbance of photosynthesis as a result of positioning the camera over the plants; a 30 s recovery time was found to be enough to allow the disappearance of any disturbance before the imaging procedure for Φ_{PSII} was begun.

Genetic variation

To estimate the genetic variation for a parameter, we calculated its heritability. Heritability, in this case broad sense heritability (H^2), is a term used in quantitative genetics that describes the portion of the total phenotypic variance in a population that is contributed by genetic variance (Visscher et al., 2008).

Genetic variance and the total phenotypic variance within an experiment were calculated with an ANOVA using type III sums of squares in a general linear model, in the IBM statistical software program SPSS. The genetic variance was estimated as the proportion of variance explained by differences between genotypes based on measurement of three plants per genotype. Standard errors for heritability were calculated using the heritabilities of three repeated experiments. Heritability for a response was calculated by first calculating the response values for a trait between two time points or two light steps. These response values were always calculated relative to the initial value of the first measurement of the two. When a relation between different parameters in different environments needed to be parameterized, we estimated the curve of the relation using regression statistics and parameterized it using the statistical model that fitted closest to the curve, with the IBM statistical software program SPSS. We then used the parameterized value for each individual to calculate the variances in the population.

Genome wide association analysis

The analysis was performed using the publicly available web application for genome-wide association mapping in Arabidopsis (GWAPP; gwas.gmi.oeaw.ac.at), using the accelerated mixed model option (Seren et al., 2012). GWAS was performed for Φ_{PSII}

measured one hour after a step-wise increase in irradiance from 100 to 550 $\mu\text{mol m}^{-2} \text{s}^{-1}$, by providing a list with average values of three biological replicates per accession. The website already 'knows' the 215 000 SNPs used for mapping, and will output a list with association scores for all these SNPs. For our analysis, we classified the SNPs with an association score > 4 as 'associated SNPs'. A core set of candidate genes was selected by cataloguing the genes which contained the associated SNPs in their coding region. The same web application was used to calculate the level of linkage disequilibrium (LD) for a SNP, and to catalogue the genes in these LD-regions (Seren et al., 2012); these genes were added to the core set of genes to form the complete list of candidate genes. A description for all candidate genes was obtained from TAIR (www.arabidopsis.org).

Gene ontology enrichment analysis

All gene ontology (GO) annotations were downloaded from TAIR (www.arabidopsis.org). The gene ontology enrichment analysis was performed for three categories: cellular component, molecular function, and biological process (Ashburner et al., 2000). Per category, the fraction of genes annotated to a certain ontology class for the list of candidate genes from GWAS was compared to the fraction of genes annotated to the same ontology class in a control group consisting of all the genes in the genome of Arabidopsis.

RESULTS

Phenotypic and genotypic variation in light response curves of various PSII parameters among 12 Arabidopsis accessions grown at $100 \mu\text{mol m}^{-2} \text{s}^{-1}$

To assess genotypic variation for the irradiance response of photosynthesis in 12 genotypically diverse Arabidopsis accessions grown under constant growth irradiance of $100 \mu\text{mol m}^{-2} \text{s}^{-1}$, the operating light use efficiency of photosystem II (Φ_{PSII}) was measured under a range of steady-state actinic irradiances. Φ_{PSII} measures the proportion of the light absorbed by PSII that is used in photochemistry, it is widely used as a proxy for the quantum yield of linear electron transport and for photosynthesis in general (Maxwell and Johnson, 2000). Figure 2A shows the light response curves of Φ_{PSII} for the 12 accessions used in this study, and figure 2B shows the light response curves of the values for the relative linear electron transport rate (rETR; the product of Φ_{PSII} and irradiance) derived from the Φ_{PSII} values in Figure 2A. The ETR is considered relative because we do not account for leaf light absorbance or the distribution of excitation energy between the two photosystems, nor apply any correction to the apparent quantum yield of PSII photochemistry provided by chlorophyll fluorescence measurements to give actual quantum yields for PSII electron transport. We will use the rETR at light saturation as a proxy for the maximum photosynthetic capacity (Pmax) in vivo (Genty et al., 1989). Figure 2B shows that when grown at $100 \mu\text{mol m}^{-2} \text{s}^{-1}$, light saturation of photosynthesis occurs between $550 - 650 \mu\text{mol m}^{-2} \text{s}^{-1}$ for all 12 accessions. While the amount of phenotypic variance among the 12 accessions increases with the increase of the actinic irradiance level so does the genetic variance, resulting in similar heritabilities (Inset, Fig. 2B).

Φ_{PSII} is the product of the quantum efficiency of the open PSII reaction centres (F_v'/F_m') and the PSII efficiency factor (q_p) (Genty et al., 1989). The loss of Φ_{PSII} can therefore be accounted for by decreases in one or both of these parameters. For plants grown at a growth irradiance of $100 \mu\text{mol m}^{-2} \text{s}^{-1}$, F_v'/F_m' remains constant at about 0.8 for actinic irradiances of $225 \mu\text{mol m}^{-2} \text{s}^{-1}$ or less, but decreases when the actinic irradiance is increased above this (Fig. 2C). Heritability for the response of F_v'/F_m' to increases in irradiance increases with increasing actinic irradiance (Fig. 2C). Similar to F_v'/F_m' , q_p also decreases with increasing actinic irradiance for plants grown at $100 \mu\text{mol m}^{-2} \text{s}^{-1}$ growth irradiance (Fig. 2D). However, unlike F_v'/F_m' , q_p shows decreases in response to actinic irradiances of less than $225 \mu\text{mol m}^{-2} \text{s}^{-1}$. In contrast to the heritability for the irradiance

response of F_v'/F_m' , the heritability for the irradiance response of q_P decreases with increasing actinic irradiance (Fig. 2D).

The values of non-photochemical quenching calculated according to the Stern-Volmer model ($NPQ; F_m/F_m' - 1$), q_P , and F_v'/F_m' measured at an actinic irradiance of $700 \mu\text{mol m}^{-2} \text{s}^{-1}$ (ie at light saturation), are shown plotted against the value of Φ_{PSII} measured at $700 \mu\text{mol m}^{-2} \text{s}^{-1}$ (Fig. 2E, 2F, and 2G), and the correlation between NPQ and F_v'/F_m' is shown in Fig. 2H. NPQ, q_P and F_v'/F_m' are linearly related to Φ_{PSII} with the correlation being negative in the case of NPQ and positive for q_P and F_v'/F_m' . The parameters F_v'/F_m' and q_P are more strongly correlated to Φ_{PSII} than is NPQ (Fig. 2E, 2F, 2G).

Figure 2 (on next page). Light response curves of various PSII parameters among 12 Arabidopsis accessions grown at $100 \mu\text{mol m}^{-2} \text{s}^{-1}$ and the correlation between parameters

(A) PSII operating light use efficiency (Φ_{PSII}) of 12 Arabidopsis accessions. Error bars indicate the standard error of the mean, $N=3$. Φ_{PSII} was measured on plants that were grown in $100 \mu\text{mol m}^{-2} \text{s}^{-1}$ for 24 days, after reaching steady state photosynthesis in five different actinic irradiances: 100, 225, 450, 700, and $1150 \mu\text{mol m}^{-2} \text{s}^{-1}$ (B) relative electron transport rates (rETR) in the presence of different actinic irradiances of 12 accessions of Arabidopsis, calculated from PSII operating light use efficiencies.; the inset shows the average heritabilities over three independent experiments for the individual measurement points and for the response of these values to actinic irradiance level; (C) light use efficiency of the open PSII reaction centres in the presence of different actinic irradiances (F_v'/F_m') of 12 accessions of Arabidopsis; (D) PSII efficiency factor (q_p) in the presence of different actinic irradiances of 12 accession of Arabidopsis; (E) correlation of Φ_{PSII} and NPQ of 12 accessions each with three replicates grown in $100 \mu\text{mol m}^{-2} \text{s}^{-1}$ and measured at light saturation ($700 \mu\text{mol m}^{-2} \text{s}^{-1}$); (F) correlation of Φ_{PSII} and q_p of 12 accessions each with three replicates grown in $100 \mu\text{mol m}^{-2} \text{s}^{-1}$ and measured at light saturation ($700 \mu\text{mol m}^{-2} \text{s}^{-1}$); (G) correlation of Φ_{PSII} and F_v'/F_m' of 12 accessions each with three replicates grown in $100 \mu\text{mol m}^{-2} \text{s}^{-1}$ and measured at light saturation ($700 \mu\text{mol m}^{-2} \text{s}^{-1}$); (H) correlation of NPQ and F_v'/F_m' of 12 accessions each with three replicates grown in $100 \mu\text{mol m}^{-2} \text{s}^{-1}$ and measured at light saturation ($700 \mu\text{mol m}^{-2} \text{s}^{-1}$)

Light use efficiency responses to different, constant growth irradiances

At an actinic irradiance of $600 \mu\text{mol m}^{-2} \text{s}^{-1}$ plants grown at $100 \mu\text{mol m}^{-2} \text{s}^{-1}$ have an average Φ_{PSII} of 0.35, while for plants grown at $200 \mu\text{mol m}^{-2} \text{s}^{-1}$ the average Φ_{PSII} is 0.48, for plants grown at $400 \mu\text{mol m}^{-2} \text{s}^{-1}$ it is 0.58 and for plants grown at $600 \mu\text{mol m}^{-2} \text{s}^{-1}$ it is 0.65 (Fig. 3A). This shows there is long-term photosynthetic acclimation to growth irradiance for Arabidopsis. Genetic variation for this acclimation is present. For example for some accessions the irradiance response of Φ_{PSII} for plants grown at $600 \mu\text{mol m}^{-2} \text{s}^{-1}$ is the same as that for those grown at $400 \mu\text{mol m}^{-2} \text{s}^{-1}$, whereas for other accessions the irradiance response of Φ_{PSII} for plants grown at a $600 \mu\text{mol m}^{-2} \text{s}^{-1}$ differs to that of plants grown at $400 \mu\text{mol m}^{-2} \text{s}^{-1}$ while the response of plants grown at 200 and $400 \mu\text{mol m}^{-2} \text{s}^{-1}$ is similar (Supplementary Fig. S1).

The value of Φ_{PSII} measured at an actinic irradiance equal to growth irradiance shows, overall, an apparently linear decrease with increasing irradiance (Fig. 3B). In detail, however, at growth irradiances above $400 \mu\text{mol m}^{-2} \text{s}^{-1}$ this decline ceases for some accessions (Fig. 3B). This leads to a heritability of 0.20 for the difference in this parameter when comparing the data obtained from plants grown at an irradiance of $600 \mu\text{mol m}^{-2} \text{s}^{-1}$ to those grown at $400 \mu\text{mol m}^{-2} \text{s}^{-1}$ (inset Fig. 3B).

Figure 3 (on next page). Light response of PSII light use efficiency (Φ_{PSII}) of 12 Arabidopsis accessions, grown in different constant growth irradiances: 100, 200, 400 or $600 \mu\text{mol m}^{-2} \text{s}^{-1}$
(A) Φ_{PSII} light response curves measured on 24-days-old plants after reaching steady state photosynthesis in four different actinic irradiances: 100, 225, 450, and $700 \mu\text{mol m}^{-2} \text{s}^{-1}$. The lines represent the average of all accessions, the area around the line represents the extent of deviation among the accessions (highest value minus lowest value in population); (B) variation in Φ_{PSII} among 12 Arabidopsis accessions, when grown at four different constant growth irradiances (100, 200, 400, and $600 \mu\text{mol m}^{-2} \text{s}^{-1}$) for 24 days and measured at actinic irradiance identical to the growth irradiance. Error bars indicate the standard error of the mean, $N=3$; the inset shows the heritabilities of the response of these values to growth irradiance level (C) variation in maximum relative electron transport rates ($r\text{ETR}$) measured at saturating actinic irradiance (P_{max}) among 12 accessions, grown at four different growth irradiances (100, 200, 400, and $600 \mu\text{mol m}^{-2} \text{s}^{-1}$) for 24 days. When grown at $100 \mu\text{mol m}^{-2} \text{s}^{-1}$, the saturating actinic irradiance level used was $600 \mu\text{mol m}^{-2} \text{s}^{-1}$, at $200 \mu\text{mol m}^{-2} \text{s}^{-1}$ this was $700 \mu\text{mol m}^{-2} \text{s}^{-1}$, at $400 \mu\text{mol m}^{-2} \text{s}^{-1}$ it was $800 \mu\text{mol m}^{-2} \text{s}^{-1}$, and at $600 \mu\text{mol m}^{-2} \text{s}^{-1}$ it was $1150 \mu\text{mol m}^{-2} \text{s}^{-1}$. Error bars indicate the standard error of the mean, $N=3$; (D) Correlation of F_v/F_m' and q_p for different growth irradiances (100, 200, 400, and $600 \mu\text{mol m}^{-2} \text{s}^{-1}$); (E) Correlation of F_v/F_m' and q_p for different actinic irradiances (100, 225, 450, 700, and $1150 \mu\text{mol m}^{-2} \text{s}^{-1}$); (F) Correlation of F_v/F_m' and q_p for the 12 different accessions of Arabidopsis; (G) Correlation of NPQ and Φ_{PSII} for different actinic irradiances (100, 225, 450, 700, and $1150 \mu\text{mol m}^{-2} \text{s}^{-1}$)

The correlation between the maximum rETR and growth irradiance shows genotypic variation (Fig. 3C). For some accessions this relationship is triphasic (Supplementary Fig. S2), with a sharp increase over the lower irradiance range ($100\text{-}200\ \mu\text{mol m}^{-2}\ \text{s}^{-1}$), a much lower increase between 200 and $400\ \mu\text{mol m}^{-2}\ \text{s}^{-1}$ growth irradiance, and a second sharp increase between 400 and $600\ \mu\text{mol m}^{-2}\ \text{s}^{-1}$. For other accessions this relationship is biphasic (Supplementary Fig. S2), while for others it is linear (Supplementary Fig. S2). Curve estimation of this relation using a cubic statistical model resulted in different fitted values for all 12 accessions (Supplementary Fig. S3). The heritability for this relation is 0.52.

The partitioning of the decrease in Φ_{PSII} into decreases in F_v'/F_m' and q_p is shown for different growth irradiance levels (Fig. 3D), actinic irradiance levels (Fig. 3E), and genotypes (Fig. 3F). While there is some variation in the partitioning of the loss of Φ_{PSII} between losses in F_v'/F_m' and q_p , this variation seems to be independent of genotype or growth irradiance. A negative correlation between NPQ and Φ_{PSII} (Fig. 2E) has already been noted, but in addition Fig. 3G also shows that considering all the data from all 12 genotypes, the correlation between Φ_{PSII} and NPQ is curvilinear, with NPQ decreasing more strongly with Φ_{PSII} at lower values of Φ_{PSII} . Overall, the correlation between Φ_{PSII} and NPQ does not show much genotypic variation or dependency on growth irradiance.

Long-term acclimation of light use efficiency to a step-wise increase in growth irradiance

During acclimation to a step-wise increase in growth irradiance from $100\ \mu\text{mol m}^{-2}\ \text{s}^{-1}$ to $600\ \mu\text{mol m}^{-2}\ \text{s}^{-1}$, F_o stays constant (Fig. 4A), whereas F_m decreases on the first day after the increase to high light (HL) and then recovers to its baseline value within 3-4 days (Fig. 4B), resulting in a decrease in F_v/F_m on day 1 after the increase to HL (Fig. 4C). This decrease in F_v/F_m is correlated significantly to the levels of Φ_{PSII} and q_p before the increase in growth irradiance (Supplementary Table S1), as well as to the levels of Φ_{PSII} and q_p on each day of the subsequent acclimation period. NPQ started to decline within the first 24 hours after the irradiance increase and continued to decline until day 3 (Fig. 4E). The level of NPQ on day 1 after the increase to HL is significantly correlated to the decrease in F_v/F_m on that same day, but this correlation disappears after the start of the acclimation of NPQ (Table S1). The decline of NPQ in the subsequent days of the acclimation period is accompanied by an increase in Φ_{PSII} (Fig. 4E; 4F). Both NPQ and Φ_{PSII} stabilize after three days of long-term acclimation.

Figure 4. Variation in long term acclimation response of 12 Arabidopsis accessions to increased growth irradiance after 24 days of growth, from $100 \mu\text{mol m}^{-2} \text{s}^{-1}$ to $600 \mu\text{mol m}^{-2} \text{s}^{-1}$ (high light, HL).

(A) F_o , (B) F_m , (C) F_v/F_m , (D) F_m' measured with an actinic irradiance level of $600 \mu\text{mol m}^{-2} \text{s}^{-1}$, (E) NPQ measured with an actinic irradiance level of $600 \mu\text{mol m}^{-2} \text{s}^{-1}$, and (F) Φ_{PSII} measured with an actinic irradiance level of $600 \mu\text{mol m}^{-2} \text{s}^{-1}$. Day 0 represents the baseline measurement taken on day 24 after sowing the plants on rockwool. All measurements were taken in the morning, 30 minutes after light onset. Error bars indicate the standard error of the mean, $N=3$. The insets show the heritabilities of the daily responses relative to the day before for the corresponding values (F_o , F_m , F_v/F_m , $F_m'(600)$, NPQ (600), or $\Phi_{PSII}(600)$).

Genotypic variation was observed for both the decline of NPQ and the increase in Φ_{PSII} during acclimation to increased growth irradiance (heritabilities insets in Figures 4E and 4F). Furthermore, there is some genotypic variation for the decrease in F_v/F_m on day 1 after the increase to HL as well as its recovery on day 2 (heritabilities in inset Fig. 4C). After three days, all the measured photosynthetic parameters had stabilized; some genotypic variation is also noted for the kinetics of this stabilization process, as shown by the heritabilities (insets, Fig. 4).

While some accessions acclimate fully (Fig. 5A and 5C) to an increase in growth irradiance (ie after acclimation to the increased irradiance their Φ_{PSII} -irradiance response becomes identical to that they have when grown continuously at this higher irradiance), others do not (Fig. 5B and 5D). Among the twelve accessions used in this study we could distinguish only these two kinds of responses; the responses for the accessions not shown in Figure 5 are in supplementary Figure S4.

Figure 5. Variation in light response curves of relative electron transport rate (rETR) of four Arabidopsis accessions grown at a low growth irradiance (growth in LL), grown in LL for 24 days followed by a high growth irradiance (HL) for 4 days (response to HL), and grown in HL for 24 days (growth in HL).

The low growth irradiance level is $100 \mu\text{mol m}^{-2} \text{s}^{-1}$; high growth irradiance level is $600 \mu\text{mol m}^{-2} \text{s}^{-1}$. Error bars indicate the standard error of the mean, $N=3$.

Genome-wide association analysis

Φ_{PSII} was measured on 344 accessions of *Arabidopsis* one day before and one hour after an increase in growth irradiance from $100 \mu\text{mol m}^{-2} \text{s}^{-1}$ to $550 \mu\text{mol m}^{-2} \text{s}^{-1}$; Φ_{PSII} measurements before and after the increase were correlated significantly, with a Pearson correlation coefficient of 0.436. At both time points the measurements were normally distributed (Supplementary figure S5), but the phenotypic distribution, and consequently also the trait heritability, was larger one hour after the increase in irradiance compared to before the increase in irradiance ($H^2=0.26$ vs $H^2=0.09$). A genome-wide association study (GWAS) was performed for the measurements taken one hour after a step-wise increase in growth irradiance to identify potential candidate genes associated with the short-term high light response of photosynthesis (Fig. 6). All of these genes are nuclear because the cytoplasmic genomes cannot be included in the analysis because neither the mitochondrial nor the chloroplast genomes have been genotyped for the *Arabidopsis* population we used (nor for any other large *Arabidopsis* population) so there are no SNPs (or any other genetic markers) available for these genomes. Any phenotypic variation arising from the variation in the cytoplasmic genetic factors will therefore not be accounted for.

Figure 6. Genome-wide association analysis of Φ_{PSII} one hour after an increase in growth irradiance from $100 \mu\text{mol m}^{-2} \text{s}^{-1}$ to $550 \mu\text{mol m}^{-2} \text{s}^{-1}$.

Based on the analysis of 344 diverse *Arabidopsis* accessions. Every point indicates the $-\log_{10}(p)$ value for all SNPs that have been tested. Different colours distinguish the SNPs mapped to one of the five chromosomes of *Arabidopsis*. The dotted line represents the arbitrary threshold for significance of $-\log_{10}(p) = 4$.

The strongest association between a SNP and the phenotype we found had a $-\log_{10}(p)$ value of 5.31, where 'p' is the probability of obtaining the association by chance. This strength of association was found twice, at position 27981096 on chromosome 1, and for position 12784017 on chromosome 3. Using an arbitrary threshold of significance for $-\log_{10}(p)$ of 4, we defined the SNPs with $-\log_{10}(p)$ values above this threshold as 'associated SNPs'. This yielded 30 associated SNPs, corresponding to 25 candidate genes (some genes contain more than one SNP), which increases to 63 candidate genes when all genes in linkage disequilibrium (LD) with these SNPs are included (Table II). Besides information on the genes localized (either directly or in LD) to the associated SNPs, Table II shows extra information about the population genetics of the associated SNPs, such as minor allele frequency in the population, the effect size on the trait, and the percentage of variation it explains. The functions, if known, of those genes directly associated with the SNPs is also described in Table II; the functions of the genes in the LD regions with the associated SNPs are described in Supplementary Table S2. No genes previously reported to be involved in photosynthesis were found among the 63 candidate genes. The candidate gene list is, however, enriched for genes encoding proteins that are targetted to the chloroplast, cytosol, and nucleus (Fig. 7A). When examined for protein function, there is enrichment for kinase activity, protein binding, transferase activity, and transporter activity (Fig. 7B), while the processes DNA/RNA metabolism, response to abiotic or biotic stimulus, response to stress, and transport are most represented (Fig. 7C). Of the 63 candidates, 13 (nuclear encoded) proteins are targetted to the chloroplast (Table III).

Table II. List of candidate genes localized to SNPs

Candidate genes are those genes containing the SNP and those genes in linkage disequilibrium (LD) with the SNP associated with a $-\log_{10}(p) > 4$ for Φ_{PSII} measured one hour after a step-wise increase in irradiance from 100 to 550 $\mu\text{mol m}^{-2} \text{s}^{-1}$, selected upon a genome wide association study on 344 *Arabidopsis* accessions. Chr., chromosome; gene, the gene to which the associated SNP localizes, if two genes are indicated, the SNP is mapped in between two genes; SNP pos., the chromosome position(s) of the SNP(s); MAF, minor allele frequency, the letter in parenthesis indicates whether it represents the Col-0 allele (C) or the non-Col-0 allele (NC); $-\log_{10}(p)$, the significance level of the associated SNP expressed as $-\log_{10}(p)$; effect size, the contribution of the Col-0 allele of the SNP on Φ_{PSII} ; perc.of.genetic.var, the percentage of genetic variation explained by the SNP; description, the annotation of the gene function as indicated in TAIR (www.arabidopsis.org); LD, the genes found to be in linkage disequilibrium ($r > 0.45$) with the indicated SNP.

DISCUSSION

Short-term response of plants to increased irradiances

In 12 genotypically diverse *Arabidopsis* accessions grown at $100 \mu\text{mol m}^{-2} \text{s}^{-1}$ there is variability in the responses of Φ_{PSII} to short-term (minutes time scale) changes in irradiance (Fig. 2A, Fig. 2B). There is more phenotypic variance for electron transport rate the closer the actinic irradiance level is to light saturation (Fig. 2B), which would be expected given that increasing irradiances move the leaf from light-limitation to light-saturation (Björkman, 1981; Evans and Poorter, 2001). In a light-limited leaf, Φ_{PSII} is close to a maximum value (c. 0.80 – 0.83) that is similar across many groups of plants (Björkman and Demmig, 1987). The value for Φ_{PSII} at steady state is due to the balance between supply side processes, that give rise to the formation of excited states of chlorophyll *a* (chl^*) in PSII following light absorption by photosystem II, and demand side processes that dissipate these chl^* photochemically (Genty et al., 1989). If supply exceeds demand then the light-use efficiency for photosynthesis must decrease. For plants grown at $100 \mu\text{mol m}^{-2} \text{s}^{-1}$ such a decrease has already occurred at an actinic irradiances equal to the growth irradiance (Fig. 2A), which implies that even at low growth irradiances acclimation did not maximise light-use efficiency. In a light-saturated leaf, Φ_{PSII} is limited by electron transport or metabolic factors that generally can differ greatly between species (Seemann, 1989; Murchie and Horton, 1997; Valladares et al., 1997) and within species (Balaguer et al., 2001; Walters et al., 2003; Ptushenko et al., 2013).

Values for heritability generally range from zero to one (Visscher et al., 2008), where a value of one means that all of the observed phenotypic variance is solely due to genetic variation. The heritability for Φ_{PSII} ranges around 0.50, independent of the actinic irradiance at which it is measured (inset Fig. 2B), from which we conclude the amount of genetic variation for short-term responses of Φ_{PSII} to increased irradiance is independent of the level of the irradiance. To further dissect the variation for photosynthetic light use efficiency, Φ_{PSII} can be broken down into its F_v'/F_m' and q_p components (Genty et al., 1989). Overall, F_v'/F_m' and q_p decrease as Φ_{PSII} decreases, but not in parallel (Harbinson et al., 1989). In the absence of photodamage or slowly reversible down-regulation of PSII (Demmig-Adams and Adams, 2006), decreases in F_v'/F_m' are due to the activation of a non-photochemical dissipation mechanism that gives rise to the q_E component of NPQ (Demmig et al., 1987). Decreases in q_p are due to the reduction of Q_A , though the relationship between Q_A redox state and q_p is non-linear (Kramer et al., 2004). In response to a moderate increase in irradiance (from 100 to $200 \mu\text{mol m}^{-2} \text{s}^{-1}$), the

decrease in Φ_{PSII} is due only to decreases in q_P (Fig. 2C and 2D). The loss of q_P at low irradiances, which is due to an over-excitation of PSII compared to PSI and not to a limitation of electron transport (Genty and Harbinson, 1996), is still correlated with a loss of light-use efficiency for carbon dioxide fixation (Hogewoning et al., 2012). The lack of any decrease in F_v'/F_m' at the lowest measurement irradiances is paralleled by the pattern of heritability for the irradiance responses of q_P and F_v'/F_m' (insets, Fig. 2C and 2D)

The parameters F_v'/F_m' and NPQ quantify the effect of inducible (ie not present in the dark-adapted state) non-photochemical dissipation in PSII on the efficiency of open PSII traps (F_v'/F_m') and the quenching of F_m (NPQ). Even if F_m' changes, the F_v'/F_m' calculated using a measured value of F_o' should be unaffected by state transitions, in contrast to the NPQ parameter. In our case F_o' was calculated from F_v , F_m and F_m' (Oxborough and Baker, 1997) and while this allows a good estimate of F_o' , it cannot estimate the impact of q_T quenching which is where the impact of using a calculated F_o' in place of a measured F_o' will be greatest. q_T quenching is due to state transitions (Horton and Hague, 1988; Quick and Stitt, 1989) on F_o' . q_T quenching (and state transitions) is limited to low irradiances (Walters and Horton, 1991; Rintamäki et al., 1997). An F_v'/F_m' based on a calculated F_o' is therefore likely to be better correlated with NPQ than would be an F_v'/F_m' based on a measured F_o' , especially at low irradiances. Figure 2E, 2F, and 2G show a high correlation of NPQ, q_P , and F_v'/F_m' with Φ_{PSII} measured at light saturation (actinic light of $700 \mu\text{mol m}^{-2} \text{s}^{-1}$). F_v'/F_m' and q_P are more strongly correlated with Φ_{PSII} than is NPQ (Fig. 2E, 2F, 2G), which is to be expected as Φ_{PSII} is the product of q_P and F_v'/F_m' . The correlation between NPQ and F_v'/F_m' (Fig. 2H) is also expected given that under the experimental conditions used both these parameters will be predominantly affected by the energy-dependent quenching mechanism that gives rise to q_E . These results suggest that there is little variability in the extent to which the loss of Φ_{PSII} can be absorbed via the thermal dissipation processes that give rise to NPQ and produce the decrease in F_v'/F_m' .

Φ_{PSII} in plants grown at different constant growth irradiances

In response to increasing growth irradiances, all accessions of Arabidopsis showed a smaller loss of Φ_{PSII} with increasing actinic irradiance (Fig. 3A). As a result, Φ_{PSII} measured at an actinic irradiance identical to the growth irradiance decreases only slightly with growth irradiance (maximally 25%, Fig. 3B). This response shows that Arabidopsis has considerable flexibility in its photosynthetic apparatus and responds strongly to high irradiances, a trait not found in all species (Murchie and Horton, 1997). Genotypic variation for this trait is minor amongst the 12 genotypes used in this study

(Fig. 3B). More genotypic variation can be found in the relationship between the rETR at light saturation and growth irradiance (Fig. 3C). For some accessions this relation is linear, for some it is bi-phasic, and for some tri-phasic, confirming the presence of separate low and high light responses in Arabidopsis (Bailey et al., 2001).

The pattern of partitioning of losses in Φ_{PSII} between F_v'/F_m' and q_p is independent of both growth irradiance (Fig. 3D) and actinic irradiance (Fig. 3E), and genotype (Fig. 3F). These results imply that non-photochemical dissipation in PSII is highly and consistently regulated across diverse genotypes grown under a range of growth irradiances. Another implication is that when evaluating and comparing the development and extent of the inducible non-photochemical dissipation processes that give rise to decreases in F_v'/F_m' and to increases in NPQ, the underlying change in PSII efficiency should be taken into account (Fig. 3G).

Long-term responses to a step-wise increase in growth irradiance

The decrease in F_v/F_m (0.02 - 0.04) one day after a step-increase in growth irradiance from 100 to 600 $\mu\text{mol m}^{-2} \text{s}^{-1}$ is due to a decrease in F_m , which is followed by a recovery in F_v/F_m , an increase in Φ_{PSII} and a decrease in NPQ (Fig. 4A, B, C). The decrease in F_v/F_m was correlated to the values for Φ_{PSII} and q_p before the increase in irradiance, as well as to the values for Φ_{PSII} , q_p , and NPQ on the first day after the increase in irradiance (Supplementary Table S1). Slowly reversible decreases in F_v/F_m are an indicator of photodamage or of slowly reversible down-regulation of PSII (Walters and Horton, 1991; Demmig-Adams and Adams, 1992; Niyogi, 1999; Demmig-Adams and Adams, 2006). We were not able to distinguish between these two mechanisms in our experiments, but overall the phenomenon of slowly reversible loss of F_v/F_m seems to occur if the short-term protection mechanisms that give rise to NPQ are insufficient to protect PSII from damage.

The kinetics of NPQ decay and Φ_{PSII} recovery after a step-increase in irradiance show genotypic variation (Fig. 4E and 4F), implying there is variation in the regulation of photosynthetic recovery after an irradiance increase, whereas the ultimate extent of acclimation after four days shows no genotypic variation. The extents of the changes in Φ_{PSII} in response to a step-increase in irradiance found by us are similar to those found by Yin et al. (2012), but their Φ_{PSII} values decreased for two days following the increase in irradiance before recovering on day three, whereas our data showed a recovery of Φ_{PSII} beginning on the first day after the increase in irradiance. This difference could be caused by the relatively greater irradiance increase they used (from 120 $\mu\text{mol m}^{-2} \text{s}^{-1}$ to 950 $\mu\text{mol m}^{-2} \text{s}^{-1}$ versus from 100 $\mu\text{mol m}^{-2} \text{s}^{-1}$ to 600 $\mu\text{mol m}^{-2} \text{s}^{-1}$ in our case), causing more

extensive slowly reversible loss of F_v/F_m . Yin et al identified two potential regulatory mechanisms that are variable among three Arabidopsis accessions in response to increased irradiance; one is the abundance of kinases that facilitate state transitions and the other is a mechanism to facilitate lateral protein traffic in the membrane by diluting chlorophyll-protein complexes with additional lipids and carotenoids (Yin et al., 2012). The variation we found for the kinetics of NPQ decay and Φ_{PSII} recovery is likely to reflect these different mechanisms found by Yin et al (2012), and in addition possible other regulatory mechanisms yet undefined.

After full acclimation to a step-wise increase in irradiance from 100 to 600 $\mu\text{mol m}^{-2} \text{s}^{-1}$, all accessions had a photosynthetic capacity higher than that achieved under a constant growth irradiance of 100 $\mu\text{mol m}^{-2} \text{s}^{-1}$ (Fig. 5, Supplementary Figure S4). In contrast to our results, a similar study performed by Athanasiou et al. (2010) revealed significant variation in the ability of different accessions to acclimate to an increased irradiance. While Athanasiou et al. increased irradiance after 8 weeks of growth at 100 $\mu\text{mol m}^{-2} \text{s}^{-1}$, we increased it after 3.5 weeks of growth. Plant age or size therefore might have an effect on the capacity of photosynthesis to respond to the increase in irradiance. We also grew the plants hydroponically while Athanasiou et al. used soil-based cultivation, and differences in plant nutritional state might have contributed to the different responses of photosynthesis. Whatever the explanation, the fact that there are these differences implies that there are extra dimensions to the irradiance responses of photosynthesis in Arabidopsis that need to be understood. There is genotypic variation for the ability of leaves grown at 100 $\mu\text{mol m}^{-2} \text{s}^{-1}$ before a step-increase in irradiance to 600 $\mu\text{mol m}^{-2} \text{s}^{-1}$ to acclimate their photosynthetic capacity to that found in leaves grown at a constant irradiance 600 $\mu\text{mol m}^{-2} \text{s}^{-1}$ (Fig. 5). A possible role for leaf anatomy in limiting the response of photosynthetic capacity in leaves subjected to an increase in irradiance has been reported (Oguchi et al., 2003) and there is variation in leaf architecture in Arabidopsis (Pérez-Pérez et al., 2002).

Natural genetic variation and GWAS

The fact that there is genetic variation for photosynthesis could mean that natural selection has favoured different optima depending on the local environment, especially since it is hard to imagine that genetic drift will be the sole cause of variation for such an important trait (Alonso-Blanco et al., 2009; Trontin et al., 2011). To investigate this it is crucial to identify the genes involved and the effect of alleles of those genes on the photosynthesis phenotype. Identifying causal allelic variation is easier when there is

substantial genetic variation for a trait, as quantified by the heritability values (Barton and Keightley, 2002) and the effect size of the QTL (Falke and Frisch, 2011). It is hard to predict how much heritability is required before a trait will be amenable to genetic analysis, as this depends on the number of loci that contribute to the heritability (i.e. the genetic complexity of the trait) and on the population used in the study (Visscher et al., 2008; Brachi et al., 2011). In this study of 12 *Arabidopsis* accessions it is clear that there are some photosynthetic traits for which heritability values look more promising for further genetic analysis than others

The heritability calculated for Φ_{PSII} in the 344 accessions used for the GWAS ($H^2=0.09$ before, and $H^2=0.26$ one hour after, the increase in growth irradiance (Figure S5) is different from the heritability calculated for the population of 12 accessions ($H^2=0.59$ before, and $H^2=0.53$ after the increase in growth irradiance; Figure 2B). Different heritabilities for the same trait in different populations can be explained by different allele frequencies (Visscher et al., 2008); in this case it looks like the small set of 12 diverse accessions already captured most of the genetic variation for Φ_{PSII} also found in the larger set of 344 accessions. Even though alleles get more heterogeneous when studying a bigger natural population (Brachi et al., 2011; Gibson, 2012), if the larger heterogeneity found in the set of 344 accessions does not contribute to larger phenotypic variation than in the set of 12 accessions, but merely a dilution of the phenotypic effect of extreme genotypes, the result will be a reduction in heritability.

Successful GWAS studies have identified an over-representation in a-priori candidate genes (Atwell et al., 2010), or identified only a small number of genes that were associated above the Bonferroni threshold of $-\log_{10}(p) = 6.50$ (Chao et al., 2012; Meijón et al., 2014). The Bonferroni threshold is a very stringent statistical test correcting for multiple testing (Holm, 1979). In our study, no genetic associations are detected with a $-\log_{10}(p)$ above the Bonferroni threshold. As the change in photosynthesis efficiency in response to an increase in irradiance is a highly polygenic trait, we expect that the effects of the individual underlying genes will be small. Such genes are likely to remain hidden in associations that do not exceed the Bonferroni threshold because of epistatic and interactive effects (Gibson, 2010; Korte and Farlow, 2013). By lowering the $-\log_{10}(p)$ threshold to 4, some of these hidden associations were revealed (Fig. 6), allowing us to select 63 candidate genes which either contained an associated SNP or were in linkage disequilibrium (LD) with the SNP (Table II). No genes previously reported to be involved in photosynthesis were found among these candidate genes. To provide validation for our approach, a gene ontology (GO) enrichment analysis was performed

from which we could extract the ontology classes that are relevant for the natural variation of our trait (Fig. 7) (Huang et al., 2009). There was enrichment for regulation of protein abundance (enriched ontology classes: golgi apparatus, kinase activity, transferase activity, protein binding, protein metabolism, response to (a)biotic stimulus or to stress), as well as to responses limited to the nucleus (enriched ontology class: nucleus) and the chloroplast (enriched ontology classes: chloroplast, cytosol, transporter activity). Out of the 63 candidate genes, 13 of the (nuclear-) encoded proteins localized to the chloroplast (Table III). Close analysis of the function of these 13 genes validates the enrichment for abiotic stress responses, as some genes are involved with the sensing of a stress (receptor; oxidative stress protein; calcium binding protein), others with regulating a stress response (chromatin assembly/disassembly; RNA modification; regulator of expression of defence genes), and others are involved with the act of responding to (photosynthetic) stress (DNA mismatch repair; protease for degrading abnormal and damaged proteins; carbohydrate transport) (Table III). Only four genes have no known function.

Conclusion

In conclusion, we have demonstrated that for *Arabidopsis* accessions there is genotypic variation for the short-term response of photosynthetic light use efficiency to a step-wise increase in growth irradiance as well as its long-term acclimation. The data also show that over the range of growth irradiances employed, the light use efficiency of photosynthesis (measured by Φ_{PSII}) acclimates strongly to the level of growth irradiance so that the Φ_{PSII} , measured at an actinic irradiance identical to the growth irradiance, only decreases slightly with higher levels of growth irradiance. A broader phenotypic distribution is found by measuring Φ_{PSII} at light saturation (Fig. 2B, 3A, 5, and supplementary Fig. S5). In relation to productivity and yield, the ability of photosynthesis to acclimate has been shown to increase plant fitness of *Arabidopsis* in a greenhouse environment where natural fluctuations in irradiance and other environmental factors would have occurred (Athanasίου et al., 2010). If there was a desire to breed *Arabidopsis* for improved photosynthetic properties leading to increased yield, more might be gained by focussing on the dynamic regulatory acclimation response of photosynthesis to different light environments instead of investigating acclimation to stable environments (Leister, 2012). The response described here will be useful when selecting light environments for optimal, uniform growth of *Arabidopsis*, and also serves as a reminder that while often grown at low irradiances ($100\text{-}200 \mu\text{mol m}^{-2} \text{s}^{-1}$), *Arabidopsis* has photosynthetic responses that are more typical of a high-light adapted plant, in accordance with its natural habitat which

is disturbed sites, possibly with light shade (Pigliucci, 1998; Mitchell-Olds and Schmitt, 2006). In addition, we have shown that for those traits for which there is considerable heritability, it is possible to use GWAS to identify novel candidates for genetic components of the plant photosynthetic response to light.

ACKNOWLEDGEMENTS

We thank Pádraic Flood for designing the trays used to grow *Arabidopsis* uniformly and image them for chlorophyll fluorescence without background noise. We thank Rob van der Schoor for his help in obtaining the chlorophyll fluorescence imaging data. The “Unifarm” section of Wageningen University is acknowledged for providing the nutrient solutions and taking care of the *Arabidopsis* plants. This project was carried out within the research programme of BioSolar Cells, co-financed by the Dutch Ministry of Economic Affairs.

Chapter 3

A regulator in anterograde signalling underlies natural variation for plant photosynthesis

ABSTRACT

Increases in irradiance levels damage the photosynthesis machinery, but plants can protect themselves from this damage and adapt to acclimate (Demmig-Adams and Adams, 1992; Walters, 2005). Natural genetic variation for this acclimation should be exploited to identify the genes involved (Van Rooijen et al., 2015). Here we show it is feasible to dissect natural genetic variation in photosynthesis efficiency down to the genomic DNA level, by confirming that allelic sequence variation at the *YELLOW SEEDLING1* (*YS1*) gene explains natural variation in *Arabidopsis thaliana* photosynthesis acclimation. *YS1* encodes a Pentatricopeptide-Repeat (PPR) protein involved in RNA editing of plastid encoded genes (anterograde signalling), (Zhou et al., 2009). A genome-wide association (GWA) study was performed in a time-course manner to genetically dissect the photosynthetic acclimation response of *Arabidopsis thaliana*. Candidate genes were prioritized according to recurrence of association over time, in combination with relevant functional clues regarding gene ontology, expression and function. Reverse genetics supported the involvement of four gene candidates. Quantitative complementation and gene expression analysis confirmed that polymorphisms in the GT-1 binding site of the light responsive element in the promoter of *YS1* are the cause of the variation in photosynthetic acclimation.

INTRODUCTION

Light, as the driving force for photosynthesis, is a conspicuously important determinant of photosynthetic activity. Genetic variation exists in plants for what constitutes a high light leaf or a low light leaf, for the range of irradiances to which the leaf is capable of responding, and for the actual photosynthetic properties that emerge from any environmental treatment. A sudden increase in growth irradiance beyond light saturation causes light stress in the photosynthetic apparatus, especially in photosystem II (PSII). Within a few seconds this provokes a protective regulatory response in the metabolism of the leaf (Demmig-Adams and Adams, 1992; Dietz, 2015). If the increased irradiance level is sustained it will induce a photosynthetic acclimation response via changes in the composition of mesophyll cells in terms of their proteins, pigments, and lipids, and other cofactors involved in electron transport and reactive-oxygen species metabolism (Bailey et al., 2004; Walters, 2005; Li et al., 2009). The regulation of photosynthetic acclimation starts with signals originating either from photoreceptors, or from the photosynthetic machinery itself, going to the nucleus and altering patterns of nuclear gene expression (retrograde signalling), (Li et al., 2009). By identifying the genomic regions that associate with phenotypic variation before or after the increase in irradiance, or both, we can distinguish those regions that are associated with photosynthetic light use efficiency in general from those genomic regions that are associated with photosynthetic acclimation to an increase in irradiance (Moore et al., 2013; Bac-Molenaar et al., 2015). Annotating the genes that give rise to the photosynthetic acclimation response will reveal at which regulatory level natural genetic variation for photosynthesis exists. Photosynthesis is a complex trait at both the physiological and genetic levels and as a result natural genetic variation in photosynthesis is an underused resource for identification of the genetic regulation of photosynthesis (Flood et al., 2011; Van Rooijen et al., 2015). The poor understanding of the genetic foundations of photosynthetic traits together with the complex relationship between photosynthesis and yield has resulted in photosynthesis being underused in plant breeding programmes (Flood et al., 2011; Driever et al., 2014). Nevertheless it does have great potential for crop improvement (Lawson et al., 2012; Long et al., 2015).

MATERIALS AND METHODS

Plant material and growth conditions

A set of 344 *Arabidopsis thaliana* (*Arabidopsis*) accessions was used for GWA, which are all part of a core set of 360 natural accessions that represent the global genetic diversity of the species (<https://www.arabidopsis.org/servlets/TairObject?type=stock&id=4501958598>) (Li et al., 2010). Sixteen accessions of the core set were not used: CS28051, CS28108, CS28808, CS28631, CS76086, CS76104, CS76110, CS76112, CS76118, CS76121, CS76138, CS76196, CS76212, CS76254, CS76257 and CS76302. An overview of all T-DNA lines that were studied can be found in Table S3.

Plants were grown as previously described (Van Rooijen et al., 2015). In short, this involved growing plants in a climate controlled growth chamber, on rockwool supplied with a nutrient solution, at a constant irradiance of $100 \mu\text{mol m}^{-2} \text{s}^{-1}$ (Philips 610 fluorescent tubes, MASTER TL5 HO, 80W). The photoperiod was set to 10h/14h day/night, temperature was set to 20/18°C (day/night), relative humidity was set at 70% and CO₂ levels were ambient. The irradiance was increased to $550 \mu\text{mol m}^{-2} \text{s}^{-1}$, at the onset of the photoperiod, on day 25 after sowing.

Chlorophyll a fluorescence imaging and analysis

Chlorophyll a fluorescence was measured using a high-throughput phenotyping system developed for *Arabidopsis*, as described previously (Van Rooijen et al., 2015). In all experiments, the photoperiod lasted from 8.00h until 18.00h CET and imaging of light use efficiency of photosystem II (Φ_{PSII}) was performed daily at 9.00h, 11.30h, 14.30h and 16.30h.

Genome-wide association (GWA) analysis

Using a mixed model (Kruijer et al., 2015), GWA analyses were performed twice for each time point, once for the Φ_{PSII} -values averaged per accession (3-4 replicates were used to produce the average value), and once on the individual measurements (using 3-4 replicates). For each time point this was achieved by associating the Φ_{PSII} -values (either averaged per accession or the individual measurements) to 215,000 SNPs that were scored either similar to the Col-0 accession (C) or not similar to the Col-0 accession (NC) (Kim et al., 2007); a minor SNP frequency of 0.05 was used to remove rare SNPs.

For each of the 215,000 SNPs, the $-\log_{10}(p)$ value was calculated, where 'p' represents the p-value of a t-test between the C- and NC-group of each SNP.

For each time point, SNPs with $-\log_{10}(p) > 4$ were classified as quantitative trait loci (QTLs); whenever two or more SNPs were in linkage disequilibrium (LD; $LD \geq 0.45$) they were lumped together to form one QTL. LD was determined by calculating the correlation coefficients between SNP calling frequencies in the population of study. The genome was divided into 2-Kbp blocks and the $-\log_{10}(p)$ values of all SNPs with $-\log_{10}(p) > 4$ within these blocks were first summed to form cumulative association scores. The scores of each 2-Kbp region were then averaged with four adjacent 2-Kbp regions, two upstream and two downstream to smooth the data. QTLs were numbered according to physical position, and identified according to time of appearance, i.e. only in low light, early in the response to high light, late in the response to high light, or at all time points.

All genes in LD with the associated SNPs for each QTL were identified by first listing all SNPs in LD ($LD \geq 0.45$) with each SNP with a $-\log_{10}(p) > 4$, and then cataloguing all genes in LD with these linked SNPs. The LD was calculated using whole genome re-sequencing data for 173 accessions out of the population of 344 accessions used for the GWA, obtained from the 1001 genomes project (<http://1001genomes.org/>; Table S4).

Candidate gene prioritization

All candidate genes in LD with the associated SNPs were prioritized in an *in silico* analysis using publicly available databases for:

- (1) gene ontology terms (www.arabidopsis.org),
- (2) gene co-expression patterns (Hruz et al., 2008) (www.genevestigator.com),
- (3) gene expression in the vegetative rosette (Schmid et al., 2005) (<http://bar.utoronto.ca/>),
- (4) known to have a function related to photosynthesis based on literature,
- (5) presence of polymorphisms segregating between two groups of 15 accessions with the most extreme phenotypes (<http://1001genomes.org/>).

Whenever a candidate gene scored positive for three out of these five criteria, it was included in the priority candidate list (Table 1). When multiple candidate genes for one QTL listed in the priority candidate list, we selected the priority candidate with segregating polymorphisms in the extreme accessions for our reverse screening. For some QTLs we chose multiple priority candidate genes for reverse screening, because multiple genes

complied with the segregating polymorphism-criterion, or because neighbouring genes with homologous/redundant functions were listed in this QTL.

Haplotype analysis

Haplotypes, representing natural alleles, were assigned based on all SNPs in the promoter and coding regions of candidate genes using the re-sequencing data of 173 accessions. Those haplotypes that occurred in >4% of the 173 accessions were then associated with photosynthetic phenotypes. Haplotypes that resulted in different photosynthetic response to increased irradiance (based on two-sided Student's t-test) were selected for quantitative complementation tests.

Quantitative complementation

Quantitative complementation to confirm involvement of allelic difference at one locus to contribute to the observed phenotypic variation (Long et al., 1996a), was performed by crossing two accessions with different alleles for the gene involved, thought to contribute to the most contrasting phenotypes, to a T-DNA insertion knock-out mutant for the gene, in accession Columbia (Col) background, as well as to the Col wild type (both used as maternal line). The phenotype of resulting F1 plants (N = 16 per cross) for their photosynthetic response to increased irradiance was determined as described above, two-way ANOVA was performed for testing significance. For quantitative complementation of YS1, we used the accession CS76172 representative for allele 3 accessions and the accession CS76133 representative for allele 4 accessions. The whole experiment for quantitative complementation was performed twice in the laboratory.

Quantitative reverse transcription PCR (qRT-PCR)

At time point 11.00 am CET (i.e. 3h after lights on) on days 24 (LL plants) and 25 (HL plants) after sowing, whole rosettes were collected and flash-frozen in liquid nitrogen. RNA was isolated according to Onate-Sánchez and Vicente-Carbajosa (2008). After normalization of RNA concentrations, cDNA was synthesized using the Iscript cDNA synthesis kit (Bio-RAD, www.bio-rad.com). qRT-PCR was performed with three technical replicates for each biological replicate using the SYBR-green master mix (Bio-RAD, www.bio-rad.com). Three biological replicates were used per accession; four accessions were analysed per haplotype. Two reference genes were used for normalization: *UBIQUITIN7* (*UBQ7*; At2g35635) and *CYTOCHROME B5 ISOFORM E* (*CB5E*; At5g53560); transcription levels of *UBQ7* were shown to be constant under excess light

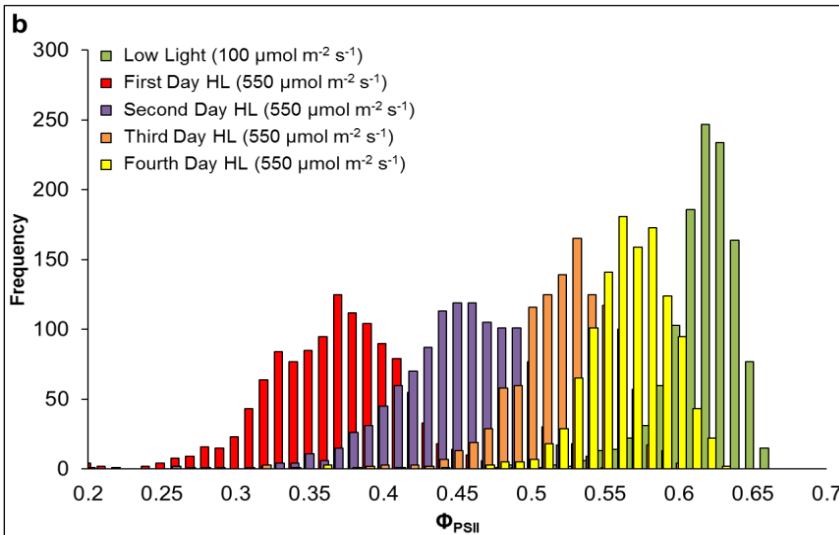

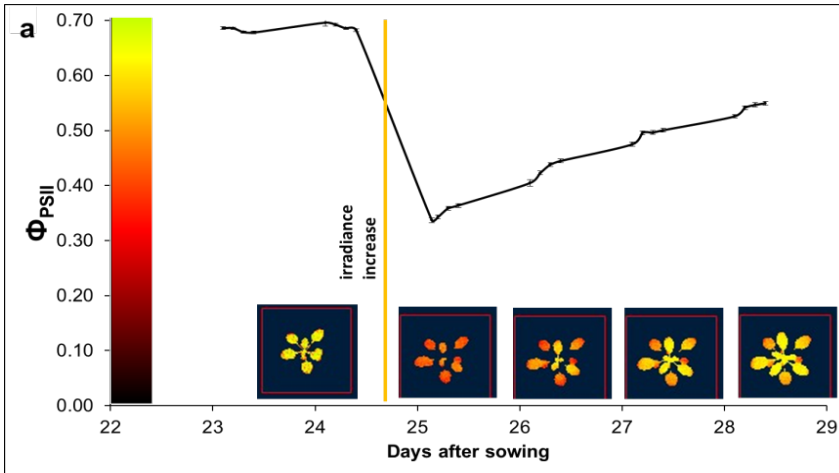

by Jung et al. (2013), and the transcription levels of *CB5E* were shown to be constant under excess light by Wunder et al. (2013). The primers used for qRT-PCR are listed in Table S5. We chose the accessions CS76113, CS28193, CS28492, and CS76297 to represent allele 1; the accessions CS76305, CS28685, CS76218, and CS76153 to represent allele 3; and the accessions CS28787, CS76133, CS76129, and CS76128 to represent allele 4. One-way ANOVA was used for testing significance.

RESULTS AND DISCUSSION

Using chlorophyll fluorescence imaging, the light-use efficiency of PSII electron transport (Φ_{PSII}) was measured in 344 Arabidopsis accessions at four time-points during the day, before and after the plants were subjected to a sudden increase in growth irradiance (Fig. 1a). The phenotypic distribution for Φ_{PSII} was narrow under steady low growth irradiance ($100 \mu\text{mol m}^{-2} \text{s}^{-1}$), got broader upon high irradiance exposure ($550 \mu\text{mol m}^{-2} \text{s}^{-1}$), and narrowed again during photosynthetic acclimation (Fig. 1b), reflecting the pattern of acclimation in the leaves – first young, then old leaves (Fig. 1a). All Φ_{PSII} measurements were highly positively correlated per accession, indicating a coordinate regulation of photosynthesis in these irradiance environments (Fig. 1c).

Figure 1 (on next page) Photosynthesis efficiency of photosystem II (Φ_{PSII}) in response to an increase in growth irradiance.

(a) Photosynthetic acclimation of Φ_{PSII} of Arabidopsis accession Col-0. Shown are the Φ_{PSII} values over time (\pm s.e.m.) and a chlorophyll fluorescent image of the same Col-0 plant measured one hour after onset of the photoperiod. (b) Frequency distribution of Φ_{PSII} measured for 344 accessions at consecutive time points in the acclimation response, three replicate plants are measured per accession. (c) Pearson's correlation analysis of Φ_{PSII} measured at consecutive time points in the acclimation response for all accessions. All correlations are significant at $p \leq 0.001$.

Genome-wide association (GWA) analysis of Φ_{PSII} at each data point resulted in a non-linear time course of associations, which is represented in a heat map of the cumulative association scores (i.e. accumulation of $-\log_{10}(p)$ values) throughout the acclimation response (Fig. 2). Twenty-six quantitative trait loci (QTLs) were identified, which were classified according to the time and duration of their appearance: seven QTLs were specific for the low irradiance phase, thirteen appeared directly after the onset of the high light treatment, three occurred later in the response to high light, and three were present throughout the experiment, independent of the irradiance level. The power of GWA studies in plants to identify true associations has proven to be relatively low for complex polygenic traits, such as photosynthesis, because of small effect sizes of each of the individual genes that together cause the phenotype (Korte and Farlow, 2013). Lowering the threshold of significance in the association analysis, e.g. below the rather strict significance threshold following a Bonferroni correction, will highlight some associations that would otherwise be ignored (Van Rooijen et al., 2015), but is also likely to increase the number of false positives (Korte and Farlow, 2013). Selection of recurrent QTLs through time allows the distinction to be made between true associations and false positive associations, strengthening the mapping power in GWA studies (Fig. 2). In addition, it allows distinction between those non-specific QTLs that are present throughout the phenotyping phase and those that are time-specific (Bac-Molenaar et al., 2015).

To focus on the acclimation response of photosynthesis we conducted no further analysis on the seven QTLs specific for the low irradiance phase of the experiment. The three QTLs present throughout the experiment were included for further analysis as they were found to increase in cumulative association score after the irradiance increase (Fig. 2). We then determined the physical positions of those SNPs corresponding to the 19 QTLs associated specifically to photosynthetic acclimation (Fig. S1). Including all genes in linkage disequilibrium (LD) with these SNPs resulted in a list of 268 candidate genes for which allelic variation may have caused the association (Table S1). Of these genes, 33 scored positive for three out of five *in silico* selection criteria based on gene function that we used to prioritize the candidate genes: gene ontology, gene co-expression, gene expression in the vegetative rosette, and the presence of segregating polymorphisms in the coding sequence (Table S2). These 33 priority candidate genes corresponded to 15 of the 19 acclimation-specific QTLs. Reverse screening with T-DNA insertion lines was performed for 20 of the 33 priority candidate genes.

Figure 2 Heat map of cumulative association scores in a genome-wide association study of Φ_{PSII} , before and after an increase in growth irradiance.

*Plant Φ_{PSII} is measured three times per day, two days in low light ($100 \mu\text{molm}^{-2}\text{s}^{-1}$) and four days in high light irradiance ($550 \mu\text{molm}^{-2}\text{s}^{-1}$). Association scores of genomic regions of 0.2 megabasepairs (Mbp) per chromosome were summed and subsequently averaged within a 1-Mbp sliding window from the top to the bottom of each of the five *A. thaliana* chromosomes. The physical distance (Mb) in each chromosome is indicated. Each quantitative trait locus (QTL) is numbered, 1-26.*

Four T-DNA insertion lines showed an aberrant phenotype for photosynthetic acclimation to increased irradiance (Fig. 3). These are insertion lines for *CTC-INTERACTING DOMAIN 7 (CID7)* (At2g26280), which encodes a protein involved in DNA binding and mismatch repair; corresponds to QTL7 of Fig. 2), *YELLOW SEEDLING 1 (YS1)* (At3g22690), which encodes a Pentatricope-Peptide-Repeat (PPR) protein involved in RNA editing of plastid encoded genes; corresponds to QTL10), *DGD1 SUPPRESSOR 1 (DGS1)* (At5g12290), which encodes a mitochondrial outer membrane protein involved in galactolipid biosynthesis; corresponds to QTL 21 of the heat map), and *ASPARAGINE SYNTHETASE 2 (ASN2)* (At5g65010), which encoding an asparagine synthetase; corresponds to QTL 26).

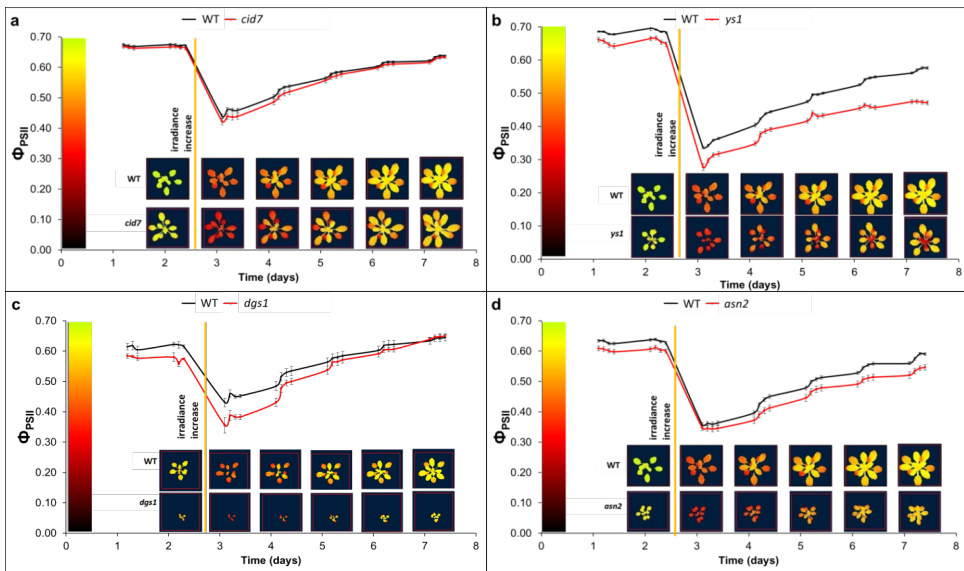

Figure 3. Photosynthesis efficiency response to increased irradiance for T-DNA insertion knock-out lines significantly different from the Col wild type (WT).

(a-d) Photosynthesis efficiency (Φ_{PSII}) response (\pm s.e.m.) over time and chlorophyll fluorescence images of plants carrying a T-DNA insertion in the (a) *CTC-INTERACTING DOMAIN 7 (CID7)*; (b) *YELLOW SEEDLING 1 (YS1)*; (c) *DGD1 SUPPRESSOR 1 (DGS1)*; or (d) *ASPARAGINE SYNTHETASE 2 (ASN2)* gene. Day 1 of the measurements corresponds to day 22 after sowing. The chlorophyll fluorescence images are taken 1 hour after lights are switched on. The yellow bar indicates a shift in irradiance from 100 to 550 $\mu\text{mol m}^{-2}\text{s}^{-1}$.

Quantitative complementation was not performed for *CID7* (the insertion line was completely sterile; Fig. S2), and failed to identify *DGS1* and *ASN2* as causal for the identified QTLs (Fig. S3 and Fig. S4) but was successful for *YS1* (significant only on day 1 after irradiance increase; Fig. 4c). Within the available re-sequence data for the Arabidopsis accessions used for the GWA, five different *YS1* alleles were distinguished (Fig. 4a). Accessions carrying alleles 2, 4 and 5 displayed the highest photosynthesis efficiency in response to high light, and were significantly different from accessions with alleles 1 and 3, which displayed the lowest photosynthesis efficiency (Fig. 4b). No single polymorphisms in *YS-1* distinguished alleles 2,4 and 5 from alleles 1 and 3 (Fig. 4a), however we observed the average transcription of *YS1-4* alleles to be higher than *YS1-3* alleles (Fig. 4d). Since gene expression is regulated by its promoter, we *de novo*-sequenced the promoter region of the Col-0 *YS1-1* allele as well as those of five accessions with allele *YS1-3* and five with allele *YS1-4*. We found three SNPs in the promoter region (Fig. S5): at positions 8 024 723; 8 025 056; and 8 025 189 bp. In addition, there was an 8-bp deletion in the promoter of allele *YS1-3*, between positions 8 024 863 and 8 024 871 bp, that was not present in the public re-sequence data (Fig. S5). Upon combining the gene expression analysis with the allelic polymorphisms, we conclude that the combination of InDel⁸⁰²⁴⁸⁶³⁻⁸⁰²⁴⁸⁷¹ and SNP⁸⁰²⁵⁰⁵⁶ causes low *YS1* expression in low light conditions (Fig. 4e), while the combination of SNP⁸⁰²⁴⁷²³ and SNP⁸⁰²⁵¹⁸⁹ causes increased *YS1* expression in high light when compared to low light conditions (Fig. 4e). Since allele 1 and allele 3 lead to low photosynthesis efficiency in response to high light (Fig. 4b), we conclude that only when the 8-bp deletion is absent and SNP⁸⁰²⁵⁰⁵⁶ = T, SNP⁸⁰²⁴⁷²³ = A, and SNP⁸⁰²⁵¹⁸⁹ = G (i.e. allele 4), gene expression is highest, leading to the highest photosynthesis efficiency in response to high light (Fig. 4e). InDel⁸⁰²⁴⁸⁶³⁻⁸⁰²⁴⁸⁷¹ overlaps with a binding site for the nuclear transcription factor GT-1, while SNP⁸⁰²⁵¹⁸⁹ locates in the core of another GT-1 binding site (Fig. S5), (Green et al., 1988; Gilmartin and Chua, 1990). No obvious transcription factor binding sites were found around SNP⁸⁰²⁴⁷²³ or SNP⁸⁰²⁵⁰⁵⁶. Mutations in GT-1 binding sites are known to affect a promoter's responsiveness to light (Gilmartin et al., 1990; Ouwkerk et al., 1999), which is consistent with the correlations we found between the differences in expression of *YS1* alleles and the differences in photosynthesis acclimation responses (Fig. 4).

Figure 4. Characterization of natural alleles of YS1.

(a) Five most abundant haplotype alleles and frequency (%) for the YS1 gene (www.arabidopsis.org). Gene orientation is 3' to 5'; two splice variants are indicated⁴. SNPs differing from the Col-0 reference genome sequence (allele 1) are marked; two SNPs of significance for this study are indicated by arrows. (b) Average photosynthesis efficiencies (Φ_{PSII}) (\pm s.e.m.) of the five haplotype alleles before (LL) and after an increase in radiance (HL), the inset shows small but significant differences between allelic groups based on T-test series. (c) Φ_{PSII} of F1 plants of crosses between wild type (WT) or *ys1* mutants with accessions carrying either YS1-3 or YS1-4 alleles confirming the QTL and the mutation in the YS1 locus are allelic, asterisks indicate significant difference in effect of allele 3 and allele 4 on the difference between Φ_{PSII} of the F1 with WT compared to the F1 with *ys1* based on two-way ANOVA. (d) Relative transcription (\pm s.e.m.) of YS1 alleles. Letters indicate significant different groups independent of LL or HL. (e) Summary of genetic polymorphisms, Φ_{PSII} and transcription of three YS1 alleles. Blue and red distinguish co-segregating traits/polymorphisms. SNP⁸⁰²⁵⁰⁵⁶ and SNP⁸⁰²⁵¹⁸⁹ are also indicated in panel (a) of this figure, whereas SNP⁸⁰²⁴⁷²³ and InDel⁸⁰²⁴⁸⁶ were not present in the re-sequence data but were found by de novo sequencing as presented in Extended Data Figure 5.

Previously, a *ys1* knock-out mutation of *YS1* was found to lead to disturbed chloroplast development in young seedlings (Zhou et al., 2009). We found that young leaves of the *ys1* mutant cannot acclimate after the irradiance increase (Fig. 3b), from which we conclude that similar developmental constraints occur in young leaves during photosynthetic acclimation to increased irradiance as in leaves of young seedlings. Differences in *YS1* expression have been found to lead to differences in the extent of sequence editing of *rpoB* transcripts, encoding for the β -subunit of the Plastid-Encoded Polymerase (PEP), (Okuda et al., 2009; Zhou et al., 2009). PEP is mainly involved in transcription of photosynthesis genes encoding photosystem I (PSI) and PSII components that are active in leaf chloroplasts (Hajdukiewicz et al., 1997). We conclude that disturbed PEP function in the *ys1* mutant leads to dysfunctional leaf maturation via aberrant transcription of genes encoding PSI and PSII components in the leaf chloroplasts.

ACKNOWLEDGEMENTS

We thank Prof. Dr. M. Koornneef, Dr. P. Flood and Dr. A. Prinzenberg for reading of the manuscript; Prof. Dr. Christoph Benning for his kind donation of the knock-out line for *DGS1*; and Dr. Akira Suzuki for his kind donation of the knock-out line for *ASN2*. This project was carried out within the research programme of BioSolar Cells, co-financed by the Dutch Ministry of Economic Affairs.

SUPPLEMENTARY TABLES AND FIGURES

Table S1. List of candidate genes co-localized with SNPs repetitively associated with Φ_{PSII} upon an increase in growth irradiance.

These are genes containing the SNP, and those genes in linkage disequilibrium (LD) with the SNP, repetitively associated ($-\log_{10}(p) \geq 4$) at different time points with Φ_{PSII} measured after an increase in growth irradiance from 100 to 550 $\mu\text{mol m}^{-2} \text{s}^{-1}$ on day 25 after sowing. The SNPs were identified in genome-wide association (GWA) studies (once using average phenotypic values and once using individual measurement values) of 344 *Arabidopsis* accessions.

QTL, the QTL number shown in Fig 2; Chr., chromosome; Cond., condition in which the QTL is identified; SNP.Pos.on.Chr., the chromosome position(s) of the SNP(s); in black: significant only in GWA using average values, in orange: significant only in GWA using individual measurement values, in green: significant in both GWA studies; MAF, minor allele frequency, with indication whether it represents the Col-0 allele (C) or the non-Col-0 allele (NC); effect size, the contribution of the Col-0 SNP allele on Φ_{PSII} ; Perc.of.gen.var., the percentage of genetic variation explained by the SNP; genes in LD region, all genes in the LD region of the indicated SNP(s), genes in red are genes associated with photosynthesis or with the chloroplast; location of gene, physical position of the gene on the indicated chromosome; description, the annotation of the gene function as indicated in TAIR (www.arabidopsis.org).

| | | | | | | AT3G04910 | 1354635-1358211 | With No Lysine (K) Kinase 1 (WNK1); serine/threonine protein kinase, whose transcription is regulated by circadian rhythm. |
| | | | | | | AT3G04920 | 1360882-1362295 | Ribosomal protein S24e family protein; FUNCTIONS IN: structural constituent of ribosome, nucleotide binding; INVOLVED IN: translation, ribosome biogenesis; LOCATED IN: in 7 components; EXPRESSED IN: 26 plant structures; EXPRESSED DURING: 13 growth stages |
| | | | | | | AT3G04930 | 1362905-1364799 | DNA-binding storekeeper protein-related transcriptional regulator |
| | | | | | | AT3G04940 | 1365165-1367759 | Encodes cysteine synthase CysD1. |
| | | | | | | AT3G04943 | 1368248-1368678 | Encodes a member of a family of small,secreted, cysteine rich protein with sequence similarity to the PCP (pollen coat protein) gene family. |
| | | | | | | AT3G04945 | 1369114-1369532 | Encodes a member of a family of small,secreted, cysteine rich protein with sequence similarity to the PCP (pollen coat protein) gene family. |
| | | | | | | AT3G04950 | 1371705-1373477 | unknown protein |
| | | | | | | AT3G04960 | 1373688-1375850 | Molecular chaperone, heat shock protein, Hsp40, DnaJ |
| | | | | | | AT3G04970 | 1376175-1378500 | DHHC-type zinc finger family protein; FUNCTIONS IN: zinc ion binding; INVOLVED IN: biological_process unknown; LOCATED IN: endomembrane system; EXPRESSED IN: 21 plant structures; EXPRESSED DURING: 13 growth stages |
| | | | | | | AT3G04980 | 1378684-1382181 | DNAJ heat shock N-terminal domain-containing protein; FUNCTIONS IN: unfolded protein binding, heat shock protein binding; INVOLVED IN: protein folding; LOCATED IN: cellular_component unknown; EXPRESSED IN: 12 plant structures; EXPRESSED DURING: 6 growth stages |
| | | | | | | AT3G04990 | 1383996-1384679 | Frigida-like protein (TAIR:AT5G27220.1) |

| | | | | | | | | | |
|----|---|----------|---------|-----------|-------|---|-----------|-----------------|--|
| 9 | 3 | early HL | 1750265 | 0.17NC | 0.02 | 8 | AT3G05810 | 1730976-1732384 | unknown protein; FUNCTIONS IN: molecular_function unknown; INVOLVED IN: biological_process unknown; LOCATED IN: mitochondrion; EXPRESSED IN: 22 plant structures; EXPRESSED DURING: 13 growth stages |
| | | | 1750573 | 0.17NC | 0.02 | | AT3G05820 | 1732991-1735757 | Encodes a putative plastid-targeted alkaline/neutral invertase. |
| | | | 1750946 | 0.17NC | 0.02 | | AT3G05830 | 1736677-1738664 | Encodes alpha-helical IF (intermediate filament)-like protein. |
| | | | 1751042 | 0.21NC | 0.02 | | AT3G05835 | 1738791-1738864 | pre-tRNA; IRNA-Ile (anticodon: TAT) |
| | | | 1755712 | 0.21NC | -0.01 | | AT3G05840 | 1740020-1743163 | encodes a SHAGGY-like kinase involved in meristem organization. |
| | | | | | | | AT3G05850 | 1743413-1746785 | transposable element gene; Mutator-like transposase family |
| | | | | | | | AT3G05860 | 1751406-1752355 | MADS-box transcription factor family protein; FUNCTIONS IN: DNA binding, sequence-specific DNA binding transcription factor activity; INVOLVED IN: regulation of transcription, DNA-dependent; LOCATED IN: nucleus; EXPRESSED IN: embryo, endosperm |
| | | | | | | | AT3G05870 | 1753467-1755631 | APC11; subunit of the anaphase promoting complex, a ubiquitin ligase complex that regulates progression through the cell cycle. |
| | | | | | | | AT3G05880 | 1755497-1756540 | Induced by low temperatures, dehydration and salt stress and ABA. Encodes a small (54 amino acids), highly hydrophobic protein that bears two potential transmembrane domains. |
| 10 | 3 | Late HL | 7992656 | 0.11(N C) | -0.02 | 7 | AT3G22550 | 7991646-7993454 | Protein of unknown function (DUF581) |
| | | | 8120853 | 0.30(N C) | 0.01 | | AT3G22555 | 7995486-7996636 | pseudogene, putative DNA methyltransferase |
| | | | | | | | AT3G22560 | 7998857-7999533 | Acyl-CoA N-acyltransferases (NAT) superfamily protein; FUNCTIONS IN: N-acetyltransferase activity; INVOLVED IN: metabolic process; LOCATED IN: membrane; EXPRESSED IN: leaf |
| | | | | | | | AT3G22570 | 8000515-8001238 | Bifunctional inhibitor/lipid-transfer protein/seed storage 2S albumin superfamily protein; FUNCTIONS IN: lipid binding; INVOLVED IN: lipid transport; LOCATED IN: endomembrane system; EXPRESSED IN: root, pollen tube |
| | | | | | | | AT3G22580 | 8002762-8003145 | Bifunctional inhibitor/lipid-transfer protein/seed storage 2S albumin superfamily protein; FUNCTIONS IN: lipid binding; INVOLVED IN: lipid transport; LOCATED IN: endomembrane system |
| | | | | | | | AT3G22590 | 8003934-8005579 | Encodes PLANT HOMOLOGOUS TO PARAFIBROMIN (PHP), a homolog of human Paf1 Complex (Paf1C) subunit Parafibromin. Human Parafibromin assists in mediating output from the Wnt signaling pathway, and dysfunction of the encoding gene HRPT2 conditions specific cancer-related disease phenotypes. PHP resides in a ~670-kDa protein complex in nuclear extracts, and physically interacts with other known Paf1C-related proteins in vivo. Loss of PHP specifically conditioned accelerated phase transition from vegetative growth to flowering and resulted in misregulation of a very limited subset of genes that included the flowering repressor FLOWERING LOCUS C. |
| | | | | | | | AT3G22600 | 8006508-8007471 | Bifunctional inhibitor/lipid-transfer protein/seed storage 2S albumin superfamily protein; FUNCTIONS IN: lipid binding; INVOLVED IN: lipid transport; LOCATED IN: anchored to membrane; EXPRESSED IN: 14 plant structures; EXPRESSED DURING: 10 growth stages |
| | | | | | | | AT3G22620 | 8008534-8009590 | Bifunctional inhibitor/lipid-transfer protein/seed storage 2S albumin superfamily protein; FUNCTIONS IN: lipid binding; INVOLVED IN: lipid transport; LOCATED IN: chloroplast envelope; EXPRESSED DURING: 4 anthesis, C globular stage, petal differentiation and expansion stage |

| | | | | | | | | |
|--|--|--|--|--|--|-----------|-----------------|--|
| | | | | | | AT3G22630 | 8009540-8010844 | Encodes 20S proteasome beta subunit PBD1 (PBD1). |
| | | | | | | AT3G22640 | 8011724-8013902 | PAP85; FUNCTIONS IN: nutrient reservoir activity; INVOLVED IN: biological_process unknown; LOCATED IN: plant-type cell wall; EXPRESSED IN: stem, seed; EXPRESSED DURING: seedling growth, seed development stages |
| | | | | | | AT3G22650 | 8014809-8015960 | CEGENDUO (CEG); CONTAINS InterPro DOMAINs: F-box domain, cyclin-like, F-box domain, Skp2-like, F-box associated domain, type 1, F-box associated interaction domain |
| | | | | | | AT3G22660 | 8016051-8017508 | rRNA processing protein-related |
| | | | | | | AT3G22670 | 8017771-8019459 | Pentatricopeptide repeat (PPR) superfamily protein; INVOLVED IN: biological_process unknown; LOCATED IN: mitochondrion; EXPRESSED IN: 21 plant structures; EXPRESSED DURING: 10 growth stages |
| | | | | | | AT3G22680 | 8019708-8020508 | Encodes RNA-DIRECTED DNA METHYLATION 1 (RDM1), forming a complex with DMS3 (AT3G49250) and DRD1 (AT2G16390). This complex is termed DDR. The DDR complex is required for polymerase V transcripts and RNA-directed DNA methylation. |
| | | | | | | AT3G22690 | 8021229-8024534 | YS1; INVOLVED IN: photosystem II assembly, regulation of chlorophyll biosynthetic process, photosystem I assembly, thylakoid membrane organization, RNA modification; LOCATED IN: chloroplast; EXPRESSED IN: 13 plant structures; EXPRESSED DURING: LP.04 four leaves visible, 4 anthesis, petal differentiation and expansion stage, E expanded cotyledon stage, D bilateral stage |
| | | | | | | AT3G22700 | 8024798-8025814 | F-box and associated interaction domains-containing protein |
| | | | | | | AT3G22710 | 8026202-8027274 | F-box family protein |
| | | | | | | AT3G22720 | 8028961-8030097 | F-box and associated interaction domains-containing protein |
| | | | | | | AT3G22730 | 8031341-8032459 | F-box and associated interaction domains-containing protein |
| | | | | | | AT3G22740 | 8032959-8035809 | homocysteine S-methyltransferase (HMT3) |
| | | | | | | AT3G22750 | 8037216-8039903 | Protein kinase superfamily protein; FUNCTIONS IN: protein serine/threonine kinase activity, protein kinase activity, kinase activity, ATP binding; INVOLVED IN: protein amino acid phosphorylation; LOCATED IN: plasma membrane; EXPRESSED IN: 13 plant structures; EXPRESSED DURING: L mature pollen stage, M germinated pollen stage, LP.04 four leaves visible, 4 anthesis, petal differentiation and expansion stage |
| | | | | | | AT3G22760 | 8044455-8047530 | CXC domain containing TSO1-like protein 1. The gene is expressed in stamens, pollen mother cells, and immature ovules. |
| | | | | | | AT3G22770 | 8048802-8052260 | F-box associated ubiquitination effector family protein |
| | | | | | | AT3G22780 | 8047684-8048667 | putative DNA binding protein (tso1) mRNA, tso1-3 allele. |
| | | | | | | AT3G22790 | 8052318-8058764 | Encodes a member of the NET superfamily of proteins that potentially couples different membranes to the actin cytoskeleton in plant cells. It binds filamentous actin and is localized to the plasma membrane and plasmodesmata. |
| | | | | | | AT3G22800 | 8062888-8064556 | Leucine-rich repeat (LRR) family protein; FUNCTIONS IN: structural constituent of cell wall; LOCATED IN: endomembrane system; EXPRESSED IN: 8 plant structures; EXPRESSED DURING: petal differentiation and expansion stage |
| | | | | | | AT3G22810 | 8068516-8071559 | FUNCTIONS IN: phosphoinositide binding; INVOLVED IN: signal transduction; LOCATED IN: cellular_component unknown; EXPRESSED IN: 10 plant structures; EXPRESSED DURING: 4 anthesis, F mature embryo stage, petal differentiation and expansion stage, E expanded cotyledon stage, D bilateral stage |

| | | | | | | | | | |
|----|---|----------|----------|----------|-------|----|-----------|-------------------|--|
| | | | | | | | AT3G22820 | 8073271-8074138 | allergen-related; FUNCTIONS IN: molecular_function unknown; INVOLVED IN: biological_process unknown; LOCATED IN: endomembrane system |
| | | | | | | | AT3G22830 | 8078820-8081051 | member of Heat Stress Transcription Factor (Hsf) family |
| | | | | | | | AT3G22840 | 8084447-8085560 | Encodes an early light-inducible protein. |
| | | | | | | | AT3G22845 | 8087307-8088747 | emp24/gp25L/p24 family/GOLD family protein; INVOLVED IN: transport; LOCATED IN: vacuole; EXPRESSED IN: 24 plant structures; EXPRESSED DURING: 15 growth stages |
| | | | | | | | AT3G22850 | 8089003-8090470 | Aluminium induced protein with YGL and LRDR motifs; FUNCTIONS IN: molecular_function unknown; INVOLVED IN: biological_process unknown; LOCATED IN: cytosol, nucleus, plasma membrane; EXPRESSED IN: 24 plant structures; EXPRESSED DURING: 15 growth stages |
| | | | | | | | AT3G22860 | 8090654-8093248 | member of eIF3c - eukaryotic initiation factor 3c |
| | | | | | | | AT3G22870 | 8096230-8097471 | F-box and associated interaction domains-containing protein |
| | | | | | | | AT3G22880 | 8097687-8100820 | Expression of the AtDMC1 is restricted to pollen mother cells in anthers and to megaspore mother cells in ovules. Similar to meiosis-specific yeast DMC gene. |
| | | | | | | | AT3G22886 | 8108021-8108622 | Encodes a microRNA that targets ARF family members ARF6 and ARF8. Essential for fertility of both ovules and anthers |
| | | | | | | | AT3G22890 | 8112723-8114992 | encodes ATP sulfurylase, the first enzyme in the sulfate assimilation pathway of Arabidopsis. It may also participate in selenium metabolism. |
| | | | | | | | AT3G22900 | 8115177-8116253 | Non-catalytic subunit specific to DNA-directed RNA polymerase IV; homologous to budding yeast RPB7 |
| | | | | | | | AT3G22910 | 8116335-8119388 | ATPase E1-E2 type family protein / haloacid dehalogenase-like hydrolase family protein; FUNCTIONS IN: calcium-transporting ATPase activity, calmodulin binding; INVOLVED IN: cation transport, calcium ion transport, metabolic process, ATP biosynthetic process; LOCATED IN: membrane; EXPRESSED IN: 12 plant structures; EXPRESSED DURING: LP.04 four leaves visible, 4 anthesis, C globular stage, petal differentiation and expansion stage |
| 11 | 3 | early HL | 12784017 | 0.37 (C) | -0.01 | 11 | AT3G31367 | 12735171-12737948 | transposable element gene; gypsy-like retrotransposon family |
| | | | | | | | AT3G31370 | 12739412-12740362 | transposable element gene |
| | | | | | | | AT3G31373 | 12742861-12745393 | transposable element gene; pseudogene, putative replication protein |
| | | | | | | | AT3G31374 | 12745879-12747374 | transposable element gene; gypsy-like retrotransposon family |

| | | | 272241 | 0.30C | 0.01 | | AT5G01720 | 266723-270483 | RN1-like superfamily protein; FUNCTIONS IN: ubiquitin-protein ligase activity; INVOLVED IN: ubiquitin-dependent protein catabolic process; LOCATED IN: endomembrane system; EXPRESSED IN: 17 plant structures; EXPRESSED DURING: 8 growth stages |
| | | | 273701 | 0.28C | 0.01 | | AT5G01730 | 272832-277561 | Encodes a member of the SCAR family. These proteins are part of a complex (WAVE) complex. The SCAR subunit activates the ARP2/3 complex which in turn act as a nucleator for actin filaments. |
| | | | 295648 | 0.17NC | 0.01 | | AT5G01740 | 280722-281445 | Nuclear transport factor 2 (NTF2) family protein; CONTAINS InterPro DOMAIN: Wound-induced protein, Wun1 |

| | | | | | | | | | |
|----|---|----------|---------|--------|-------|-----------|-----------------|--|--|
| | | | 296004 | 0.33NC | -0.01 | | AT5G01747 | 287586-287734 | Encodes a microRNA that targets several genes containing NAC domains including NAC1. Overexpression leads to decreased NAC1 mRNA and reduced lateral roots. Loss of function mutants have increased NAC1 and increased number of lateral roots. Also targets ORE1 to negatively regulate the timing of leaf senescence |
| | | | 298229 | 0.17NC | 0.01 | | AT5G01750 | 289765-291326 | Protein of unknown function (DUF567); FUNCTIONS IN: molecular_function unknown; INVOLVED IN: biological_process unknown; LOCATED IN: chloroplast; EXPRESSED IN: 23 plant structures; EXPRESSED DURING: 13 growth stages |
| | | | 299476 | 0.14NC | 0.01 | | AT5G01760 | 291712-294304 | ENTH/VHS/GAT family protein; FUNCTIONS IN: protein transporter activity; INVOLVED IN: intracellular protein transport, intra-Golgi vesicle-mediated transport; LOCATED IN: Golgi stack, intracellular |
| | | | 302045 | 0.19NC | 0.01 | | AT5G01770 | 294313-301984 | Encodes one of two Arabidopsis RAPTOR/KOG1 homologs. RAPTOR proteins are binding partners of the target of rapamycin kinase that is present in all eukaryotes and play a central role in the stimulation of cell growth and metabolism in response to nutrients. Mutations in this gene have no visible effects on embryo or plant development |
| | | | 304375 | 0.42NC | -0.01 | | AT5G01780 | 302267-304188 | 2-oxoglutarate-dependent dioxygenase family protein; LOCATED IN: cellular_component unknown; EXPRESSED IN: 21 plant structures; EXPRESSED DURING: 11 growth stages |
| | | | 305676 | 0.42C | 0.01 | | AT5G01790 | 304897-305696 | unknown protein; FUNCTIONS IN: molecular_function unknown; INVOLVED IN: biological_process unknown; LOCATED IN: chloroplast; EXPRESSED IN: 19 plant structures; EXPRESSED DURING: 13 growth stages |
| | | | 308976 | 0.50C | 0.01 | | AT5G01800 | 306968-308908 | saposin B domain-containing protein; FUNCTIONS IN: molecular_function unknown; INVOLVED IN: N-terminal protein myristoylation, lipid metabolic process; LOCATED IN: endomembrane system; EXPRESSED IN: 23 plant structures; EXPRESSED DURING: 15 growth stages |
| | | | 309253 | 0.39NC | 0.01 | | | | |
| 20 | 5 | early HL | 987180 | 0.22C | 0.01 | 10 | AT5G03750 | 984796-985497 | unknown protein; BEST Arabidopsis thaliana protein match is: Transducin/WD40 repeat-like superfamily protein (TAIR:AT5G03450.1) |
| | | | 987216 | 0.27C | 0.01 | | AT5G03760 | 985675-990549 | encodes a beta-mannan synthase that is required for agrobacterium-mediated plant genetic transformation involves a complex interaction between the bacterium and the host plant. 3' UTR is involved in transcriptional regulation and the gene is expressed in the elongation zone of the root. |
| | | | 988003 | 0.24C | 0.01 | | | | |
| 21 | 5 | early HL | 3975495 | 0.27NC | -0.02 | 11 | AT5G12290 | 3974171-3978160 | DGS1, encodes a mitochondrial outer membrane protein, involved in galactoglycerolipid biosynthesis. The dgd1 mutant phenotype is suppressed in the dgs1 mutant background. |
| | | | 3980151 | 0.10NC | -0.02 | | AT5G12300 | 3978313-3979795 | Calcium-dependent lipid-binding (CaLB domain) family protein |
| | | | | | | AT5G12310 | 3980226-3982442 | RING/U-box superfamily protein; | |
| | | | | | | AT5G12320 | 3982684-3984078 | FUNCTIONS IN: zinc ion binding ankyrin repeat family protein | |

| | | | | | | | | | |
|----|---|-------------|--------------------|-----------------|---------------|----|------------------------|--|--|
| 22 | 5 | early HL | 6034111 6180615 | 0.19NC 0.43C | 0.01 -0.01 | 10 | AT5G18160 AT5G18170 | 6002770- 6003909 6006039- 6008472 | F-box and associated interaction domains-containing protein GDH1; encodes the 43 kDa alpha-subunit of the glutamate dehydrogenase with a putative mitochondrial transit polypeptide and NAD(H)- and alpha-ketoglutarate-binding domains. Mitochondrial localization confirmed by subcellular fractionation. Combines in several ratios with GDH2 protein (GDH-beta) to form seven isoenzymes. Catalyzes the cleavage of glycine residues. May be involved in ammonia assimilation under conditions of inorganic nitrogen excess. The enzyme is almost exclusively found in the mitochondria of stem and leaf companion cells. H/ACA ribonucleoprotein complex, subunit Gar1/Naf1 protein; FUNCTIONS IN: snRNA binding, pseudouridine synthase activity, RNA binding; LOCATED IN: chloroplast thylakoid membrane, membrane; EXPRESSED IN: 14 plant structures; EXPRESSED DURING: LP.06 six leaves visible, 4 anthesis, F mature embryo stage, petal differentiation and expansion stage, E expanded cotyledon stage |
| | | | 6797296 | 0.45NC | 0.01 | | AT5G18180 | 6008561- 6009605 | Protein kinase family protein; FUNCTIONS IN: protein serine/threonine kinase activity, protein kinase activity, kinase activity, ATP binding; INVOLVED IN: protein amino acid phosphorylation; LOCATED IN: cellular_component unknown; EXPRESSED IN: 24 plant structures; EXPRESSED DURING: 15 growth stages |
| | | | 6797770 | 0.48C | 0.01 | | AT5G18190 | 6009967- 6014689 | encodes an adenylyltransferase |
| | | | | | | | AT5G18200 | 6015225- 6016782 6017865- 6019993 | NAD(P)-binding Rossmann-fold superfamily protein; FUNCTIONS IN: oxidoreductase activity, binding, catalytic activity; INVOLVED IN: oxidation reduction, metabolic process; EXPRESSED IN: 22 plant structures; EXPRESSED DURING: 13 growth stages |
| | | | | | | | AT5G18220 | 6018914- 6020453 | O-Glycosyl hydrolases family 17 protein; FUNCTIONS IN: cation binding, hydrolase activity, hydrolyzing O-glycosyl compounds, catalytic activity; INVOLVED IN: carbohydrate metabolic process; LOCATED IN: anchored to membrane |
| | | | | | | | AT5G18230 | 6021444- 6027249 | transcription regulator NOT2/NOT3/NOT5 family protein; FUNCTIONS IN: transcription regulator activity; INVOLVED IN: negative regulation of transcription, regulation of transcription; LOCATED IN: nucleus; EXPRESSED IN: 24 plant structures; EXPRESSED DURING: 15 growth stages |
| | | | | | | | AT5G18240 | 6028285- 6030802 | Encodes MYR1 (MYR1). |
| | | | | | | | AT5G18250 | 6033702- 6035380 | unknown protein; FUNCTIONS IN: molecular_function unknown; INVOLVED IN: biological_process unknown; LOCATED IN: mitochondrion; EXPRESSED IN: 23 plant structures; EXPRESSED DURING: 13 growth stages |
| | | | | | | | AT5G18260 | 6036202- 6038106 | RING/U-box superfamily protein; FUNCTIONS IN: zinc ion binding |
| | | | | | | | AT5G18270 | 6040919- 6042938 | Arabidopsis NAC domain containing protein 87 (ANAC087); FUNCTIONS IN: sequence-specific DNA binding transcription factor activity; INVOLVED IN: multicellular organismal development, regulation of transcription; LOCATED IN: cellular_component unknown; EXPRESSED IN: 12 plant structures; EXPRESSED DURING: LP.06 six leaves visible, LP.04 four leaves visible, 4 anthesis, C globular stage, petal differentiation and expansion stage |

| | | | | | | | | |
|--|--|--|--|--|--|-----------|-----------------|--|
| | | | | | | AT5G18470 | 6127797-6129285 | Curculin-like (mannose-binding) lectin family protein; FUNCTIONS IN: sugar binding; INVOLVED IN: response to karrikin; LOCATED IN: plant-type cell wall; EXPRESSED IN: 22 plant structures; EXPRESSED DURING: 12 growth stages |
| | | | | | | AT5G18475 | 6129237-6131015 | Pentatricopeptide repeat (PPR) superfamily protein; FUNCTIONS IN: molecular function unknown; INVOLVED IN: biological process unknown; LOCATED IN: chloroplast; EXPRESSED IN: 22 plant structures; EXPRESSED DURING: 13 growth stages |
| | | | | | | AT5G18480 | 6131203-6133906 | plant glycogenin-like starch initiation protein 6 (PGSIP6); FUNCTIONS IN: transferase activity, transferring hexosyl groups, transferase activity, transferring glycosyl groups; INVOLVED IN: carbohydrate biosynthetic process, biosynthetic process; LOCATED IN: membrane; EXPRESSED IN: guard cell, leaf |
| | | | | | | AT5G18490 | 6134152-6136765 | Plant protein of unknown function (DUF946) |
| | | | | | | AT5G18500 | 6138489-6141630 | Protein kinase superfamily protein; FUNCTIONS IN: protein serine/threonine kinase activity, protein kinase activity, kinase activity, ATP binding; INVOLVED IN: protein amino acid phosphorylation; LOCATED IN: plasma membrane; EXPRESSED IN: 22 plant structures; EXPRESSED DURING: 13 growth stages |
| | | | | | | AT5G18510 | 6141778-6143886 | Aminotransferase-like, plant mobile domain family protein |
| | | | | | | AT5G18520 | 6144963-6146570 | Encodes a candidate G-protein Coupled Receptor that is involved in the regulation of root growth by bacterial N-acyl-homoserine lactones (AHLs) and plays a role in mediating interactions between plants and microbes. |
| | | | | | | AT5G18525 | 6146743-6153742 | protein serine/threonine kinases;protein tyrosine kinases;ATP binding;protein kinases; FUNCTIONS IN: protein serine/threonine kinase activity, protein tyrosine kinase activity, protein kinase activity, ATP binding; INVOLVED IN: protein amino acid phosphorylation; LOCATED IN: CUL4 RING ubiquitin ligase complex; EXPRESSED IN: 22 plant structures; EXPRESSED DURING: 13 growth stages |
| | | | | | | AT5G18540 | 6153869-6156166 | unknown protein |
| | | | | | | AT5G18550 | 6160178-6163130 | Zinc finger C-x8-C-x5-C-x3-H type family protein; FUNCTIONS IN: zinc ion binding, nucleic acid binding; INVOLVED IN: biological process unknown; LOCATED IN: cellular component unknown; EXPRESSED IN: 17 plant structures; EXPRESSED DURING: 8 growth stages |
| | | | | | | AT5G18560 | 6164587-6165991 | Encodes PUCHI, a member of the ERF (ethylene response factor) subfamily B-1 of ERF/AP2 transcription factor family. The protein contains one AP2 domain. There are 15 members in this subfamily including ATERF-3, ATERF-4, ATERF-7, and leafy petiole. PUCHI is required for morphogenesis in the early lateral root primordium of Arabidopsis. Expressed in early floral meristem (stage 1 to 2). Required for early floral meristem growth and for bract suppression. |
| | | | | | | AT5G18570 | 6171661-6174833 | Encodes AtObgC, a plant ortholog of bacterial Obg. AtObgC is a chloroplast-targeting GTPase essential for early embryogenesis. Mutations in this locus result in embryo lethality. The protein is dually localized in the stroma and the inner envelope membrane and is involved in thylakoid membrane biogenesis and functions primarily in plastid ribosome biogenesis during chloroplast development. |

| | | | | | | | | | |
|----|---|----------|----------|-------|-------|---|-----------|-------------------|--|
| | | | | | | | AT5G18580 | 6174996-6178401 | FASS1; fass mutants have aberrant cell shapes due to defects in arrangement of cortical microtubules. Encodes a protein highly conserved in higher plants and similar in its C-terminal part to B' regulatory subunits of type 2A protein phosphatases. Interacts with an Arabidopsis type A subunit of PP2A in the yeast two-hybrid system. |
| | | | | | | | AT5G18590 | 6178354-6182761 | Galactose oxidase/kelch repeat superfamily protein |
| | | | | | | | AT5G18600 | 6183258-6183954 | Thioredoxin superfamily protein; FUNCTIONS IN: electron carrier activity, arsenate reductase (glutaredoxin) activity, protein disulfide oxidoreductase activity; INVOLVED IN: cell redox homeostasis; LOCATED IN: cellular_component unknown; EXPRESSED IN: 18 plant structures; EXPRESSED DURING: 10 growth stages |
| | | | | | | | AT5G20110 | 6791487-6793346 | Dynein light chain type 1 family protein; FUNCTIONS IN: microtubule motor activity; INVOLVED IN: microtubule-based process; LOCATED IN: microtubule associated complex; EXPRESSED IN: 19 plant structures; EXPRESSED DURING: 11 growth stages |
| | | | | | | | AT5G20120 | 6795366-6797172 | unknown protein |
| | | | | | | | AT5G20130 | 6797440-6798899 | unknown protein |
| | | | | | | | AT5G20140 | 6798923-6800977 | SOUL heme-binding family protein |
| 23 | 5 | early HL | 17186178 | 0.35C | -0.01 | 8 | AT5G42870 | 17185463-17189681 | PAH2; the PAH2 gene encodes a phosphatidate phosphohydrolase. Mutant analysis revealed that it involvement in galactolipid synthesis pathway, and the membrane lipid remodeling |
| | | | 17187071 | 0.35C | -0.01 | | AT5G42880 | 17191577-17194131 | Plant protein of unknown function (DUF827) |
| | | | 17187390 | 0.35C | -0.01 | | | | |
| 24 | 5 | early HL | 18812710 | 0.39C | -0.01 | 8 | AT5G46360 | 18806821-18808224 | Encodes ATKCO3, a member of the Arabidopsis thaliana K+ channel family of AITPK/KCO proteins. ATKCO3 is targeted to the vacuolar membrane. Forms homomeric ion channels in vivo. |
| | | | 18872155 | 0.42C | -0.01 | | AT5G46370 | 18809576-18811772 | Encodes AITPK2 (KCO2), a member of the Arabidopsis thaliana K+ channel family of AITPK/KCO proteins. AITPK2 is targeted to the vacuolar membrane. May form homomeric ion channels in vivo. |
| | | | 18872623 | 0.34C | -0.01 | | AT5G46380 | 18813088-18815974 | Kinase-related protein of unknown function (DUF1296) |
| | | | 18872638 | 0.34C | -0.01 | | AT5G46390 | 18816585-18819348 | Peptidase S41 family protein; FUNCTIONS IN: serine-type peptidase activity; INVOLVED IN: proteolysis, intracellular signaling pathway; LOCATED IN: chloroplast thylakoid lumen |
| | | | 18873842 | 0.34C | -0.01 | | AT5G46400 | 18820032-18824650 | PRP39-2; INVOLVED IN: RNA processing; LOCATED IN: intracellular; EXPRESSED IN: 21 plant structures. EXPRESSED DURING: 13 growth stages |
| | | | 18874929 | 0.49C | -0.01 | | AT5G46410 | 18825103-18829221 | Encodes a SCP1-like small phosphatase (SSP). Three SSPs form a unique group with long N-terminal extensions: AT5G46410 (SSP4), AT5G11860 (SSP5), AT4G18140 (SSP4b). SSP4 and SSP4b were localized exclusively in the nuclei, whereas SSP5 accumulated in both nuclei and cytoplasm. All three SSPs encodes active CTD phosphatases like animal SCP1 family proteins, with distinct substrate specificities; SSP4 and SSP4b could dephosphorylate both Ser2-PO(4) and Ser5-PO(4) of CTD, whereas SSP5 dephosphorylated only Ser5-PO(4). |
| | | | 18875337 | 0.32C | -0.01 | | AT5G46420 | 18829955-18832953 | 16S rRNA processing protein RimM family; FUNCTIONS IN: ribosome binding, nucleotidyltransferase activity; INVOLVED IN: metabolic process, rRNA processing, ribosome biogenesis; LOCATED IN: chloroplast; EXPRESSED IN: 22 plant structures. |

| | | | | | | | | | |
|----|---|----------|----------|--------|-------|----|-----------|-------------------|--|
| | | | 18875477 | 0.34C | -0.01 | | AT5G46430 | 18833267-18834564 | Ribosomal protein L32e; FUNCTIONS IN: structural constituent of ribosome; INVOLVED IN: translation, ribosome biogenesis; LOCATED IN: ribosome, cytosolic large ribosomal subunit |
| | | | | | | | AT5G46440 | 18834643-18835153 | FUNCTIONS IN: molecular_function unknown; INVOLVED IN: biological_process unknown; LOCATED IN: endomembrane system |
| | | | | | | | AT5G46450 | 18835618-18839546 | Disease resistance protein (TIR-NBS-LRR class) family; FUNCTIONS IN: transmembrane receptor activity, nucleoside-triphosphatase activity, nucleotide binding, ATP binding; INVOLVED IN: signal transduction, defense response, apoptosis, innate immune response; LOCATED IN: intrinsic to membrane; EXPRESSED IN: 18 plant structures; EXPRESSED DURING: 11 growth stages |
| | | | | | | | AT5G46460 | 18840305-18842398 | Pentatricopeptide repeat (PPR) superfamily protein; INVOLVED IN: biological_process unknown; LOCATED IN: mitochondrion; EXPRESSED IN: 20 plant structures; EXPRESSED DURING: 11 growth stages |
| | | | | | | | AT5G46470 | 18842701-18849741 | Encodes RPS6 (RESISTANT TO P. SYRINGAE 6), a member of the TIR-NBS-LRR class resistance protein. |
| | | | | | | | AT5G46490 | 18850776-18853843 | Disease resistance protein (TIR-NBS-LRR class) family; FUNCTIONS IN: transmembrane receptor activity, nucleoside-triphosphatase activity, nucleotide binding, ATP binding; INVOLVED IN: signal transduction, apoptosis, defense response, innate immune response; LOCATED IN: intrinsic to membrane |
| | | | | | | | AT5G46500 | 18856454-18857787 | unknown protein; BEST Arabidopsis thaliana protein match is: disease resistance protein (TIR-NBS-LRR class) family (TAIR:AT5G46260.1) |
| | | | | | | | AT5G46510 | 18860451-18867013 | Disease resistance protein (TIR-NBS-LRR class) family; FUNCTIONS IN: transmembrane receptor activity, nucleoside-triphosphatase activity, nucleotide binding, ATP binding; INVOLVED IN: signal transduction, defense response, apoptosis, innate immune response; LOCATED IN: intrinsic to membrane; EXPRESSED IN: 21 plant structures; EXPRESSED DURING: 12 growth stages |
| | | | | | | | AT5G46520 | 18867767-18872415 | Disease resistance protein (TIR-NBS-LRR class) family; FUNCTIONS IN: transmembrane receptor activity, nucleoside-triphosphatase activity, nucleotide binding, ATP binding; INVOLVED IN: signal transduction, defense response, apoptosis, innate immune response; LOCATED IN: intrinsic to membrane |
| | | | | | | | AT5G46530 | 18875525-18876898 | AWPM-19-like family protein; FUNCTIONS IN: molecular_function unknown; INVOLVED IN: biological_process unknown; LOCATED IN: endomembrane system, membrane |
| 26 | 5 | early HL | 25956134 | 0.46C | -0.01 | 13 | AT5G64910 | 25940711-25944114 | unknown protein |
| | | | 25963073 | 0.46C | -0.01 | | AT5G64930 | 25945712-25948341 | Regulator of expression of pathogenesis-related (PR) genes. Participates in signal transduction pathways involved in plant defense (systemic acquired resistance -SAR). Encodes a member of ATH subfamily of ATP-binding cassette (ABC) proteins. |
| | | | 25967700 | 0.36NC | 0.01 | | AT5G64940 | 25948973-25953822 | Encodes CDKC:2, part of a CDKC kinase complex that is targeted by Cauliflower mosaic virus (CaMV) for transcriptional activation of viral genes. Also regulates plant growth and development. Co-localizes with spliceosomal components in a manner dependent on the transcriptional status of the cells and on CDKC2-kinase activity. Expression of CDKC2 modifies the location of spliceosomal components. |
| | | | 25968943 | 0.28NC | 0.01 | | AT5G64960 | 25955381-25958995 | |

| | | | | | | | | | |
|--|--|--|----------|-------|-------|--|-----------|-----------------------|--|
| | | | 25975808 | 0.48C | -0.01 | | AT5G64980 | 25960775- 25963235 | unknown protein |
| | | | 25976943 | 0.32C | -0.01 | | AT5G65000 | 25964960- 25967393 | Nucleotide-sugar transporter family protein; FUNCTIONS IN: nucleotide-sugar transmembrane transporter activity; sugar:hydrogen symporter activity; INVOLVED IN: carbohydrate transport, nucleotide-sugar transport; LOCATED IN: integral to membrane, Golgi membrane |
| | | | | | | | AT5G65005 | 25967824- 25968638 | Polynucleotidyl transferase, ribonuclease H-like superfamily protein; FUNCTIONS IN: nucleic acid binding; INVOLVED IN: biological_process unknown; LOCATED IN: cellular_component unknown |
| | | | | | | | AT5G65010 | 25969190- 25972575 | Encodes asparagine synthetase (ASN2). |
| | | | | | | | AT5G65020 | 25973815- 25975726 | Annexin2; annexins are calcium binding proteins that are localized in the cytoplasm. When cytosolic Ca ²⁺ increases, they relocate to the plasma membrane. They may be involved in the Golgi-mediated secretion of polysaccharides. |
| | | | | | | | AT5G65030 | 25975697- 25976305 | unknown protein |

Table S2. Shortlist of 33 prioritized candidate genes potentially underlying quantitative trait loci (QTLs) for photosynthesis acclimation in Arabidopsis

These are the QTLs indicated in Fig. 2. These genes pass three out of the five selection criteria summarized in columns 2 to 6: gene ontology (genes in red have ontology terms 'chloroplast', 'photosynthesis', or 'light stress'); gene co-expression (values in red have a correlation value (r^2) that exceeds 0.800 when considering expression of light response genes from light intensity-associated microarray experiments; a dash means the gene is not represented on the microarray chip used for gene expression analysis); gene expression in the vegetative rosette; gene function; and presence of segregating polymorphisms in the gene coding sequence. The last column indicates for which genes T-DNA insertion mutants were screened; AT1G74190, AT5G64960, AT5G64980, AT5G65000, and AT5G65030 were included in T-DNA screening because of extreme high LD in these two QTLs ($LD>0.9$).

| QTL | gene | r^2 | rosette expression | known role in photosynthesis | polymorphisms in extreme accessions | T-DNA line screened |

Figure S1 Heat map of all 202 SNPs with $-\log_{10}(p) \geq 4$ for at least one time point in genome-wide association study of $\Phi PSII$ on consecutive time points before and after an increase in growth irradiance from 100 to 550 $\mu\text{mol m}^{-2} \text{s}^{-1}$ on day 25 after sowing. Three time points are indicated per day, i.e. 9.00h (1), 11.30h (2) and 14.30h (3), either on two days before (low light, L) or four days after (high light, H) the increase in growth irradiance; 'GWAS' indicates if the SNPs were significant when the GWA analysis was performed on the $\Phi PSII$ -values averaged per accession (AV) or on single measurement (SM) values, or both (AV + SM).

| Chr. | SNP position | GWAS | L1.1 | L1.2 | L1.3 | L2.1 | L2.2 | L2.3 | H1.1 | H1.2 | H1.3 | H2.1 | H2.2 | H2.3 | H3.1 | H3.2 | H3.3 | H4.1 | H4.2 | H4.3 |

Figure S2. Characterization of natural alleles of CID7

(a) Overview of haplotype alleles and frequencies for the CID7 gene (AT2G26280), gene orientation is 3' to 5', SNPs differing from the Col-0 reference genome sequence (allele 1) are marked; **(b)** Average photosynthesis efficiencies (Φ_{PSII}) (\pm SE) of the seven haplotype alleles before and after an increase in radiance at the onset of day 3, alleles 1 and 2, 1 and 4, 2 and 7 and 4 and 7 are statistically significantly different; **(c)** relative mRNA expression (\pm SE) of CID7 in two T-DNA insertion lines (SALK_011487 and SAIL_888_F10) as determined by qRT-PCR. * indicates significant difference with the Col wild type.

Figure S3. Characterization of natural alleles of DGS1

(a) Overview of haplotype alleles and frequencies for the *DGS1* gene (*AT5G12290*), gene orientation is 3' to 5', SNPs differing from the *Col-0* reference genome sequence (not indicated) are marked; (b) average photosynthesis efficiencies (Φ_{PSII}) (\pm SE) of the seven haplotype alleles before and after an increase in radiance at the onset of day 3, only allele 7 responds statistically significantly different from the other alleles; (c) In a quantitative complementation analysis, alleles 5 and 7 respond similarly regarding Φ_{PSII} in F1 plants upon crossing appropriate accessions with *Col* wild type or with T-DNA insertion mutant line *SAIL_391_F04*.

Figure S4. Characterization of natural alleles of ASN2

(a) Overview of haplotype alleles and frequencies for the *ASN2* gene (*AT5G65010*), gene orientation is 5' to 3', SNPs differing from the *Col-0* reference genome sequence (not indicated) are marked; (b) average photosynthesis efficiencies (Φ_{PSII}) (\pm SE) of the seven haplotype alleles before and after an increase in radiance at the onset of day 3, only allele 2 responds statistically significantly different from the other alleles; (c) In a quantitative complementation analysis, alleles 2 and 5 respond similarly regarding Φ_{PSII} in F1 plants upon crossing appropriate accessions with *Col* wild type or with T-DNA insertion mutant line *SALK_043167*.

Figure S5. Genomic DNA sequence of the promoters of YS1 alleles 1, 3 and 4.
 YS1 promoter sequence alignment (sequence is indicated 3' to 5', as YS1 is positioned in reverse orientation on chromosome 3 between 8021229 - 8024534 bp). The ATG-start codon is indicated with an arrowed box, with the arrow indicating the direction of translation. Polymorphisms are highlighted in pink. The yellow boxes indicated potential GT-1 binding sites (in opposite orientations relative to each other).

Chapter 4

Photosynthetic response to increased irradiance is mediated through heat shock response and lipid membrane remodelling

Roxanne van Rooijen^{1,2}, Jeremy Harbinson², Mark G.M Aarts¹

¹Laboratory of Genetics & ²Horticulture and Product Physiology, Wageningen University, Droevendaalsesteeg 1, 6708 PB Wageningen, The Netherlands

ABSTRACT

Plants have evolved several mechanisms for sensing increased irradiance; they are known to sense it using several classes of photoreceptors (phototropins, phytochromes and cryptochromes), and to sense it through biochemical (reactive oxygen species, ROS) and metabolic signals. This results in the activation of heat shock genes and the activation of the transcription factor LONG HYPOCOTYL 5 (HY5, mediated by the cryptochrome photoreceptor 1, CRY1). Here we show the existence of another gene expression response pathway in Arabidopsis. This pathway starts with the SPX1-mediated activation of the transcription factor PHR1 and leads to the activation of several galactolipid biosynthesis genes. Gene expression analysis of accessions Ga-0 and Ts-1, with contrasting phenotypes for response to increased irradiance, showed stronger activation of heat responsive genes in Ga-0 and the opposite in Ts-1, when compared to Col-0, in line with the differences in the efficiency of photosynthesis. Furthermore, the SPX1/PHR1-mediated gene activation pathway acting on galactolipid biosynthesis genes was found to be active in Ga-0 as well as Col-0, but not in Ts-1, contributing to the difference between both accessions with contrasting increased irradiance response phenotypes.

INTRODUCTION

The light-use efficiency of photosynthesis depends on the molecular, structural and physiological state of the plant (Eberhard et al., 2008; Zhu et al., 2008; Foyer et al., 2012). The physiological state of the plant depends on many environmental factors, of which the level of irradiance has a direct relation with photosynthesis light-use efficiency as it is the driving force for photosynthesis. At low irradiances, photosynthesis is fully light-limited and photosynthetic light-use efficiency is maximal. At irradiances above the light-limiting level, light-use efficiency decreases with increasing irradiances, resulting in the overall phenomenon of light-saturation of photosynthesis at elevated irradiances (Long et al., 1994; Sinclair and Muchow, 1999). The decrease in light-use efficiency from its maximum under wholly light-limiting conditions implies that irradiance exceeds the capacity for photosynthetic metabolism (Long et al., 1994). A consequence of increased irradiance is an increase in the rate of damaging side reactions of photosynthesis that occurs as a result of the reactive nature of many intermediates formed (Vass, 2012). Reactive oxygen species (ROS), mainly singlet oxygen (O^{\bullet}), superoxide ($O_2^{\bullet-}$) and hydrogen peroxide (H_2O_2), are the most conspicuous damaging by-products of photosynthesis (Asada, 2006; Vass, 2012). The stress response of photosynthesis appears to reduce the formation of ROS, especially under high growth irradiances (Scheibe et al., 2005; Suzuki et al., 2012). The state of the photosynthesis apparatus – its composition, organisation and regulation – is thus under complex control that operates at the physiological and molecular levels. An increase in irradiance, leading to excess, will initially provoke a rapid physiological response, including q_E type quenching and increased CO_2 fixation activity (Demmig-Adams and Adams, 1992; Niyogi, 1999; Li et al., 2009). If persistent this increased irradiance will result in longer term acclimation of the photosynthetic apparatus, obvious on both transcript and protein level (Walters, 2005; Li et al., 2009). Different species and genotypes display different capacities to acclimate their photosynthetic apparatus to an irradiance increase so it is reasonable to infer that this is at least partly genetically determined (Van Rooijen et al., 2015).

An increase in irradiance brings about changes not only in photosynthesis, but also in leaf temperature and photoreceptor activity (Larcher, 2003). The transcriptome changes provoked by an increase in irradiance are therefore complex, part of them caused by the temperature increase rather than the irradiance increase (Swindell et al., 2007). Increased irradiance and increased temperature together induce a stress response by activation of heat shock proteins and the generation of ROS originating from the

chloroplast, the latter of which is required for the photosynthetic acclimation response to excess light (Rossel et al., 2002; Vanderauwera et al., 2005; Jung et al., 2013).

In addition to the increased temperature and the induced generation of ROS, plants detect increases in the irradiance level through their cryptochrome photoreceptors (Kleine et al., 2007). Of the two distinct plant cryptochromes in *Arabidopsis thaliana* (Arabidopsis) (CRY1 and CRY2), only CRY1 responds to increases in irradiance by initiating a transcriptional response mediated by the transcription factor LONG HYPOCOTYL 5 (HY5), (Kleine et al., 2007; Lee et al., 2007).

The gene expression response to increased irradiance initiated by the heat shock factors and the response initiated via the HY5 transcription factor are considered to be two distinct gene activation pathways, distinct both in function and in time (Yamamoto et al., 2004). The heat shock factors are thought to induce a direct response to cope with the ROS that are already formed; whereas the HY5-induced gene expression responds slower, and is thought to function in protecting the cells from newly formed ROS.

All transcriptome studies of Arabidopsis that analysed the response to increased irradiance so far, have used the Col-0 accession. This study includes additional, natural, accessions of Arabidopsis with contrasting photosynthesis responses to increased irradiance (Van Rooijen et al., 2015), to reveal which common and genotype-specific transcriptional responses are associated with differences in acclimation of photosynthesis efficiency. In addition, analysing different time-points within one study allows identification of transient expression patterns throughout the acclimation response.

MATERIALS AND METHODS

Plant material and growth conditions

Three *Arabidopsis* accessions, Columbia-0 (Col-0, CS76113), Gabelstein-0 (Ga-0, CS76133) and Tossa de Mar-1 (Ts-1, CS76268), were grown as previously described (Van Rooijen et al., 2015). In short, the plants were grown on rockwool in a 10h/14h day/night cycle, with the temperature set at 20/18°C (day/night), and relative humidity set at 70%. CO₂ levels were ambient. Under controlled conditions, plants in the light were kept at a constant irradiance of 100 $\mu\text{mol m}^{-2} \text{s}^{-1}$ (Philips 610 fluorescent tubes, MASTER TL5 HO, 80W). In the increased irradiance treatment, the irradiance was increased to 550 $\mu\text{mol m}^{-2} \text{s}^{-1}$ at the onset of the photoperiod on the 25th day after sowing. In the increased temperature treatment, the irradiance was kept at 100 $\mu\text{mol m}^{-2} \text{s}^{-1}$, but the temperature was increased from 20°C to 30 °C during the day. Photosynthesis efficiency was measured as previously described (Van Rooijen et al., 2015).

RNA sample preparation

On the 25th day after sowing, rosettes of plants were harvested 1 hour (1h) after the start of the photoperiod and flash-frozen in liquid nitrogen. Only for the Col-0 accession this was repeated at 3.5 hours (3.5h) after the start of the photoperiod, as well as one day later, at 1 hour after the start of the photoperiod, so 25 hours (25h) after increasing the irradiance to 550 $\mu\text{mol m}^{-2} \text{s}^{-1}$. Three rosettes for each accession-treatment combination were pooled as one sample for RNA isolation, in three replications.

Total RNA was extracted using the Direct-zol RNA mini prep kit from Zymo Research (www.zymoresearch.com). The RNA quality control, labelling, microarray hybridization and data extraction were performed at ServiceXS B.V. (part of GenomeScan B.V., Leiden, The Netherlands). The RNA concentration was measured using a DropSense96 spectrophotometer (Trinean N.V., Gentbrugge, Belgium). The RNA quality and integrity was determined using Lab-on-Chip analysis on the Agilent 2100 BioAnalyzer (Agilent TEchnologies, Inc., Santa Clara, CA, U.S.A.). Single-strand-cDNA (ss-cDNA) was prepared using the Ovation[®] PicoSL WTA System V2 (NuGEN Technologies, Inc., San Carlos, CA, U.S.A.) according to the manufacturer's specifications, with an input of 50 ng total RNA. Labelling and fragmentation of the ss-cDNA was performed with the Encore[™] Biotin Module (NuGEN Technologies, Inc., San Carlos, CA, U.S.A.).

Microarray hybridization, scanning and data analysis

Per sample, 2.5 µg of the labeled ss-cDNA was hybridized onto an AraGene 1.1ST Array plate (Affymetrix, Santa Clara, CA, U.S.A.). Hybridization and scanning was performed on a GeneTitan (Affymetrix, Santa Clara, CA, U.S.A.). Image analysis and extraction of raw expression data was performed with the Affymetrix Expression Console™ v1.2.1. with “Gene-level Default: RMA-Sketch” settings. Raw data were analysed using the Bioconductor packages in the statistical programming language R (<http://www.r-project.org/>)(Gentleman et al., 2004). The microarray oligonucleotide probe data were gene annotated using the TAIRT v19 cdf file (<http://brainarray.mbni.med.umich.edu/Brainarray/Database/CustomCDF/19.0.0/tairt.asp>) and gene expression was normalized using the Robust Multi-array Average (RMA) algorithm (Irizarry et al., 2003), after which a linear model was fitted for every gene. The empirical Bayes method was used to determine significant differences between the samples and the Benjamini and Hochberg method was used for adjustment of the P values for multiple testing (Benjamini and Hochberg, 1995; Efron and Tibshirani, 2002).

Quantitative Reverse Transcription PCR (qRT-PCR)

In a separate experiment, but with identical experimental set-up as used for the microarray experiment, rosettes were likewise harvested, on the 25th day after sowing, for all accession-treatment combinations at 1 and 3.5 h after the start of the photoperiod, and immediately frozen in liquid nitrogen. Three rosettes for each accession-treatment combination were pooled as one sample for RNA isolation, in three replications. RNA was extracted according to Onate-Sánchez and Vicente-Carbajosa (2008). After normalization of RNA concentrations, cDNA was synthesized using the Iscript cDNA synthesis kit from Bio-RAD (www.bio-rad.com). qRT-PCR was performed with three technical replicates for each biological replicate using the SYBR-green mastermix from Bio-RAD. Three reference genes were used for normalization: *UBIQUITIN7 (UBQ7, At2g35635)*, *CYTOCHROME B5 ISOFORM E (CB5E, At5g53560)*, and *UBIQUITIN THIOESTERASE (At1g28120)*, based on previous report. Expression levels of *UBQ7* and *CB5E* were previously found to be constant under excess light (Jung et al., 2013; Wunder et al., 2013), and expression levels of *UBIQUITIN THIOESTERASE* were previously found to be stable in several genome-wide expression studies involving irradiance changes (Genevestigator database (Hruz et al., 2011), <https://genevestigator.com/gv/>). The primers used for qRT-PCR are listed in Table S7.

RESULTS

Heat shock response and RNA binding protein genes are among the core group of genes responding to an increase in irradiance

Three *Arabidopsis* accessions, Col-0, Ga-0 and Ts-1, were grown for 25 days under $100 \mu\text{mol m}^{-2} \text{s}^{-1}$ growth irradiance (low light, LL), and then shifted to an increased irradiance ($550 \mu\text{mol m}^{-2} \text{s}^{-1}$, high light, HL), a condition which saturates photosynthesis (Van Rooijen et al., 2015). Upon exposure to increased irradiance, the accessions show different photosynthesis efficiencies, as determined by measuring ΦPSII (the light-use efficiency of photosystem II (PSII) electron transport, also known as F_q'/F_m') (Fig. 1A). A rosette transcriptome analysis was performed for these accessions to identify a core set of genes of which the response associates with increased photosynthesis efficiency. This analysis will also be used to identify accession-specific responses. In addition, a time-series transcriptome analysis was performed, for Col-0 only, to investigate the effect of diurnal rhythm on gene expression.

The effect of the genotype is larger than the time effect, although both can be distinguished from control experiments (Fig. 1B). Genes that were statistically significantly more than 1.4-fold up- or down-regulated after the increased irradiance treatment compared to the control treatment were identified (Fig. 2), which we will further refer to as 'responsive genes'.

Figure 1. Genotypic effect on photosynthetic response to increased irradiance

(A) Representative photosynthetic (Φ_{PSII}) phenotypes for Arabidopsis accessions Col-0, Ts-1 and Ga-0, grown for 24 days in $100 \mu\text{mol m}^{-2} \text{s}^{-1}$ growth irradiance and subsequently 6 days in $550 \mu\text{mol m}^{-2} \text{s}^{-1}$ growth irradiance, measured from day 23 (first day of measurement) until day 31, at four time-points per day; (B) Dendrogram on Pearson distance measure between microarray-based transcriptome data representing gene expression in rosettes of Arabidopsis accessions Col-0, Ts-1 and Ga-0 exposed to low light (LL; $100 \mu\text{mol m}^{-2} \text{s}^{-1}$ growth irradiance) control conditions or increased irradiance (high light, HL; $550 \mu\text{mol m}^{-2} \text{s}^{-1}$ growth irradiance), sampled at 1h, 3.5h, and 25h after lights on (control, LL) or after the switch to increased irradiance (HL), in three experimental replicates (R1, R2 and R3).

A total of 752, resp. 440 genes was more than 1.4-fold up- or down-regulated, when compared to untreated plants, in at least one of the three accessions one hour after the irradiance increase from 100 to $550 \mu\text{mol m}^{-2} \text{s}^{-1}$ (Fig. 2A). Of these responsive genes, 161 up-regulated and 59 down-regulated genes were shared among all three accessions (Fig. 2A). A total of 1664, resp. 1356 genes was more than 1.4-fold up- or down-regulated, when compared to untreated Col-0 plants either at 1, 3 or 25 hours after the switch to increased irradiance (Fig. 2B). Of these responsive genes, 115 up-regulated genes and 120 down-regulated genes were responding at all time-points (Fig. 2B).

Figure 2. Genotype- and time-specific gene expression response to increased irradiance

(A) Venn diagrams displaying the number of significantly ($p=0.05$) differentially (more than 1.4-fold up- or down-regulated) expressed genes when comparing rosettes of control plants ($100 \mu\text{mol m}^{-2} \text{s}^{-1}$ growth irradiance) of three accessions (Col-0, Ga-0, or Ts-1) to those of plants one hour after exposure to increased irradiance ($550 \mu\text{mol m}^{-2} \text{s}^{-1}$ growth irradiance); (B) Idem when comparing rosettes of control Col-0 plants ($100 \mu\text{mol m}^{-2} \text{s}^{-1}$ growth irradiance) at 1 hour (h), 3.5 h or 25 h after lights on, to those of Col-0 plants at 1 h, 3.5 h or 25 h after exposure to increased irradiance ($550 \mu\text{mol m}^{-2} \text{s}^{-1}$ growth irradiance); (C) Idem when comparing differentially expressed genes shared by all accessions (a) with those shared by all time-points in Col-0 (b). Arrows indicate up- and down-regulation compared to controls.

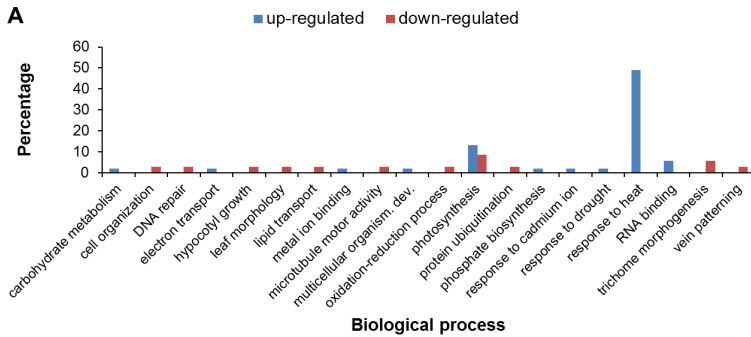

In order to establish a core set of Arabidopsis genes constituting the general response to an increase in irradiance, the genes in common to both comparisons (i.e. accessions and time-points) were selected (Fig. 2C), meaning 53 up- and 35 down-regulated genes (Tables S1 and S2). Gene ontology analysis of this core set showed that heat shock response, photosynthesis and RNA binding were enriched processes among the up-regulated genes; while only modest enrichment for a genes involved in photosynthesis was found among the down-regulated genes (Fig. 3A). Figure 3B lists all genes classified in one of the enriched biological processes, and their expression difference when compared to control plants. Most prominent in terms of induced expression are the heat response genes, while most of the down-regulated genes show only modest down-regulation (Fig. 3B).

Comparing the fold changes of the core responsive genes between the three accessions (Ga-0, Ts-1, and Col-0) or between the three time-points (1, 3.5, and 25 hrs after exposure to irradiance increase) revealed differential responsiveness (e.g. 15-fold upregulated in Col-0, 1.8-fold in Ga-0, and 5-fold in Ts-1; where all are above 1.4-fold change, but 15-, 1.8- and 5-fold are significantly different from each other) between

accessions and/or time-points for some of the core genes (Tables S1 and S2). To distinguish if this differential responsiveness was high light specific or was common between the three accessions and/or three time-points, we selected the differentially responsive genes between accessions or between time-points that were not differentially expressed in control conditions and referred to those as high light specifically differentially responsive genes. Two, resp. 27, resp. 9 genes were found high light specifically differentially responsive between accessions, between time-points, or between both accessions and time-points (Tables S1 and S2). The two high light specifically responsive core genes up-regulated to different extent between accessions were *DEHYDRATION RESPONSIVE ELEMENT BINDING 2A (DREB2A)* and *SERINE-ARGININE RICH RNA BINDING PROTEIN 45a (SR45a)*, annotated to photosynthesis-related transcription factor activity and RNA alternative splicing, respectively (Fig. 3B and Table S1). The 27 high light specifically responsive core genes up-regulated to different extent between time-point or between both accessions and time-points were all heat shock response genes (Fig. 3B and Table S1). Given the annotations of these high light specific responsive core genes, we focussed on similar processes/functions when analysing the accession- and time-point-specific gene expression responses.

Figure 3 (on next page). Gene ontology and functional annotation of Arabidopsis rosette genes showing core transcriptional response upon exposure to increased irradiance.

(A) Gene ontology enrichment for biological process of Arabidopsis rosette genes differentially expressed at 1, 3.5 or 25 hrs after exposure to increased irradiance when compared to control plants, either when comparing accessions Ga-0, Ts1, and Col-0 or time-points (Col-0 only); (B) Heat map for fold changes in increased irradiance conditions versus control conditions of core genes with biological functions in photosynthesis (yellow highlighted), response to heat (grey highlighted), and RNA binding (green highlighted). Core genes are more than 1.4-fold up- or down regulated in all time-points and accessions. For the complete gene list see Supplementary Tables S1 and S2. G-1 = Ga-0 time-point 1h; T-1 = Ts-1 time-point 1h; C-1 = Col-0 time-point 1h; C-3.5 = Col-0 time-point 3.5h; C-25 = Col-0 time-point 25h.

Differential expression in genes for heat shock response and lipid remodelling when comparing phenotypically contrasting accessions

Accession-specific expression responses were characterized between three photosynthetically contrasting accessions to identify any associations between gene expression responses and photosynthesis efficiency responses to increased irradiance. A total of 752, resp. 440 genes was more than 1.4-fold up- or down-regulated, when compared to untreated plants, in at least one of the three accessions one hour after the irradiance increase from 100 to 550 $\mu\text{mol m}^{-2} \text{s}^{-1}$ (Fig. 2A). Of these 1192 responsive genes, 155 genes were identified as accession-specific responsive genes (Tables S3 and S4), meaning they were also differentially ($P=0.05$) responsive between two or three accessions when comparing Col-0, Ga-0 and Ts-1 (e.g. 15-fold upregulated in Col-0, 1.8-fold in Ga-0, and 5-fold in Ts-1). Of these 155 accession-specific responsive genes, 123 were found high light specifically differentially responsive between accessions (and not different between accessions independent of irradiance, Tables S3 and S4).

The up-regulated accession-specific responsive genes were enriched for the biological processes of heat shock response, lipid remodelling and photosynthesis (Fig. 4A). The down-regulated time-point-specific responsive genes were enriched for cell organization, photosynthesis response, and RNA binding (Fig. 4A). Figure 4B lists all genes classified in one of the enriched biological processes, and their expression difference when compared to control plants. Most prominent in terms of expression are the heat shock response genes (Fig. 4B).

Differential expression in genes for photosynthetic and heat shock response when comparing sequential time-points after increased irradiance in Col-0

Time-point-specific expression responses were characterized in Col-0 between three time-points after irradiance increase to identify transient expression patterns throughout the acclimation response and to study the effect of diurnal rhythms on gene expression response during long-term acclimation. A total of 1664, resp. 1356 genes was more than 1.4-fold up- or down-regulated, when compared to untreated Col-0 plants either at 1, 3 or 25 hours after the switch to increased irradiance (Fig. 2B). When comparing the fold changes of these 2785 responsive genes, 2280 genes were identified as time-specific responsive genes, meaning they were differentially ($P=0.05$) responsive between two or three time-points when comparing 1, 3.5, and 25 hours after irradiance increase (e.g. 15-fold upregulated at 1 hour and 1.8-fold at 3.5 hour after irradiance increase; at both time-

points classified above 1.4 but time-point-specifically). Increasing the threshold to 2.0 fold up- or down regulated to be more exclusive resulted in 229, resp. 155 genes more than 2.0 fold up- or down-regulated (Supplementary Tables S5 and S6). Of these 384 time-specific responsive genes, 270 were found high light specifically differentially responsive between time-points (Tables S5 and S6).

The more than 2.0 fold up-regulated time-point-specific responsive genes were enriched for the biological processes of photosynthesis response, heat shock response, lipid remodelling, RNA binding and carbohydrate metabolism (Fig. 5A). The down-regulated time-point-specific responsive genes were enriched for cell organization, photosynthesis response, and lipid remodelling (Fig. 5A). Figure 5B lists all time-point-specific responsive genes classified in one of the enriched biological processes, and their expression difference when compared to control plants.

Figure 4. Gene ontology and functional annotation of Arabidopsis rosette genes showing accession-specific transcriptional response upon exposure to increased irradiance.

(A) Gene ontology enrichment for biological process of Arabidopsis rosette genes differentially ($P=0.05$) expressed at 1 hr after exposure to increased irradiance when comparing control plants with plants exposed to increased irradiance in minimal one accession and differentially ($P=0.05$) expressed between two or three accessions when comparing Ga-0, Ts1, and Col-0; (B) Heat map for fold changes in increased irradiance conditions versus control conditions of accession-specific responsive genes ($P=0.05$) with enriched biological functions photosynthesis (yellow highlight), response to heat (grey highlight), RNA binding (green highlight), carbohydrate metabolism (blue highlight), photoreceptor activity (pink highlight), lipid remodelling (light-green highlight), and cell organization (orange highlight). Accession-specific responsive genes are more than 1.4-fold up- or down regulated in minimal one accession measured 1h after irradiance increase and in addition are differentially ($P=0.05$) up- or down-regulated between two or three accession when comparing Ga-0, Ts1, and Col-0. Only enriched biological processes among these accession-specific responsive genes are presented, for complete list see Supplementary Tables S3 and S4. G-1 = Ga-0 time-point 1h; T-1 = Ts-1 time-point 1h; C-1 = Col-0 time-point 1h.

Figure 5. Gene ontology and functional annotation of Arabidopsis Col-0 rosette genes showing time-point-specific transcriptional response upon exposure to increased irradiance.

(A) Gene ontology enrichment for biological process of Arabidopsis Col-0 rosette genes differentially ($P=0.05$) expressed after exposure to increased irradiance when comparing control plants with plants exposed to increased irradiance at minimal one time-point and differentially ($P=0.05$) expressed between two or three time-points when comparing 1, 3.5 and 25 hrs after exposure to increased irradiance; (B) Heat map for fold changes in transcription when comparing increased irradiance conditions versus control conditions of time-specific responsive genes ($P=0.05$) with enriched biological functions photosynthesis (yellow highlight), response to heat (grey highlight), RNA binding (green highlight), carbohydrate metabolism (blue highlight), photoreceptor activity (pink highlight), lipid remodelling (light-green highlight), and cell organization (orange highlight). Time-specific responsive genes are more than 2.0-fold up- or down regulated in minimal one time-point after irradiance increase in Col-0 increase and in addition are differentially ($P=0.05$) up- or down-regulated between two or three time-points when comparing 1, 3.5 and 25 hrs after exposure to increased irradiance. Only enriched biological processes among these time-specific responsive genes are presented, for complete list see Supplementary Tables S5 and S6. C-1 = Col-0 time-point 1h; C-3.5 = Col-0 time-point 3.5h; C-25 = Col-0 time-point 25h. The colour-scale is similar to figures 3 and 4.

Light response versus heat response

In order to distinguish between the direct effects of an increase in irradiance and the indirect effect caused by the increase in temperature due to the increased irradiance, the expression of nine genes, selected from the classes of differentially expressed genes with enriched biological functions (Fig. 3, 4 and 5), was determined using quantitative reverse transcriptase PCR (qRT-PCR). For this experiment, plants were grown at either increased irradiance or increased temperature but no increased irradiance, conditions, and compared to plants grown under control conditions (no increased irradiance, no increased temperature). Of the core genes we selected two genes involved in RNA binding (*SR45a* [At1g07350] and *SR30* [At1g09140]) to compare their expression under these conditions (Fig. 6). The up-regulation of *SR45a* and *SR30* in response to excess light was observed for Col-0 and Ga-0 at 1 h after lights on, but not in Ts-1 and not after 3.5 h after lights on in either accession. Both genes were also induced by increased temperature, not significantly different from the induction by increased irradiance.

Another core responsive gene encodes for the transcription factor *GLK2* (At5g44190), which was down-regulated upon increased irradiance (Fig 3.). Both Col-0 and Ga-0 showed a down-regulation of *GLK2*, at 1h after the irradiance increase, but not after the temperature increase (Fig. 6C). After 3.5 hours *GLK2* was found to be up-regulated in Col-0 in response to an irradiance increase, but not to a temperature increase. Expression of *GLK2* in Ts-1 was unaltered when comparing treatments.

Figure 6 (on next page). Expression of genes selected for their response to increased irradiance to distinguish response to increase irradiance and response to increased temperature

Expression differences measured as fold changes (average \pm SE) upon qRT-PCR analysis, of genes selected for their specific response based on the microarray analysis, determined at 1 h (1H; orange) and 3.5 h (3.5H; red) after an irradiance increase from 100 to 550 $\mu\text{mol m}^{-2} \text{s}^{-1}$ (HL), as well as 1 h (light blue) and 3.5 h (dark blue) after a temperature increase from 20 to 30°C (HT), compared to control conditions, 1 h after lights on; (A) SR45a [At1g07350]; (B) SR30 [At1g09140]; (C) GLK2 [At5g44190]; (D) HSFA2 [At2g26150]; (E) HOP3 [At4g12400]; (F) CPN60beta2 [At3g13470]; (G) SPX1 [At5g12150]; (H) GDPD1 [At3g02040]; (I) DREB2A [At5g05410]. Letters indicate statistically significant differences as determined by analysis of variance ($P < 0.05$).

The largest group among both the core as well as accession-specific responsive genes were heat shock response genes (Fig. 3A). Three of these genes were selected for further analysis, *HSFA2* [At2g26150]), up-regulated in all accessions; *HOP3* [At4g12400]), most upregulated in Col-0; and *CPN60BETA2* [At3g13470], up-regulated only in Col-0 and Ga-0. *HSFA2* was confirmed to be induced 1 h after both the irradiance increase and the temperature increase in both Col-0 and Ga-0, but only after 3.5 h after temperature increase in Ts-1 (Fig. 6D). Expression of *HOP3* was confirmed by qRT-PCR to be increased one hour after the irradiance increase as well as after temperature increase for Col-0 and for Ga-0, though after temperature increase the expression of *HOP3* was induced in Ts-1 similarly as in Col-0 and Ga-0 (Fig. 6E). In all accessions the activation of *HOP3* had significantly reduced by 3.5 hours after the induction of any stress treatment. Expression of *CPN60Beta2* was not confirmed by qRT-PCR to be up-regulated in response to irradiance increase (Fig. 6F).

Another biological process enriched among the accession-specific responsive genes is classified as lipid remodelling (Fig. 4A and 5A). Two genes (*SPX1* [At5g12150] and *GDPD1* [At3g02040]) were selected for further analysis. qRT-PCR showed that expression of *SPX1* was strongly activated in Col-0 and to lesser extent in Ga-0 during the first hour after the irradiance increase (Fig. 6G). Similar results were found for *GDPD1*, except for an increase in *GDPD1* expression for Ts-1 after 3.5 hours of exposure to high temperature (Fig. 6H).

The transcription factor *DREB2A* [At5g05410] is well known for its response to drought, but is also known to be heat responsive (Sakuma et al., 2006). It was found among the accession-specific responsive genes (Fig. 4B), and was selected to further analyse its expression response to excess light and to a temperature increase without a light increase. qRT-PCR confirmed that expression was increased only in Col-0 in the first hour of the irradiance increase, but not after only temperature increase (Fig. 6I).

Of the nine genes selected for qRT-PCR confirmation of the microarray results, eight were confirmed to be responsive to increased irradiance (Fig. 6). Of these eight confirmed genes, four genes (*GLK2*, *SPX1*, *GDPD1*, and *DREB2*) were found to be irradiance increase specific and not to be responsive to temperature increase only (Fig. 6). All of these four genes were accession-specifically responsive, with an absent response in Ts-1 for all four genes. The four genes responsive to both irradiance and temperature increase (*SR30*, *SR45a*, *HSFA2*, and *HOP3*) were accessions-specific as well, with also for these genes an absent response in Ts-1. For *SR30*, *SR45a*, *HSFA2*,

and *HOP3*, the accession-specific effect was more pronounced after irradiance increase than after temperature increase (Fig. 6).

DISCUSSION

This study investigated whether association of increases in Φ_{PSII} with time following an increase in growth irradiance (Fig. 1A) with gene expression patterns (Fig. 2A) in natural accessions of *Arabidopsis* would reveal which gene responses are associated with high photosynthesis efficiency acclimation. In addition, analysing different time-points in Col-0 within one study (Fig. 2B) would allow identification of transient expression patterns throughout the acclimation response. A core set of *Arabidopsis* genes was established by selecting the core responsive genes in common to both comparisons (i.e. accessions and time-points, Fig. 2C), constituting the general response to an increase in irradiance.

Transient gene expression through time reveals photosynthetic acclimation

Plants have evolved three mechanisms for sensing increased irradiance. This can be through several classes of photoreceptors (phototropins, phytochromes and cryptochromes), responding to irradiance levels directly; but also through biochemical signals (reactive oxygen species, ROS); and metabolic signals (sugar levels or protein phosphorylation status), (Li et al., 2009). Our study reveals gene expression responses in all three sensing mechanisms (Fig. 7A). It confirms the photoreceptor response mediated through the CRY1/HY5 genetic regulators leading to induced expression of many flavonoid biosynthesis genes (Fig. 5B) (Vanderauwera et al., 2005; Kleine et al., 2007); it confirms the biochemical response mediated through heat shock factors leading to induced expression of ROS scavenging genes (Fig. 5B); and it confirms the metabolite response through the up-regulated ERF/AP2 transcription factor family (Fig. 5B), known to sense distorted metabolite levels in response to increased irradiance, leading to systemic induced acclimation (Rossel et al., 2007; Moore et al., 2014; Vogel et al., 2014). In addition, it identifies another increased irradiance response, sensing distorted internal phosphate metabolite levels leading to induced expression of membrane lipid remodelling genes (Fig. 7B).

Photosynthetic acclimation is known to occur in several phases. Around three hours after the irradiance increase the initial photoprotection response, provoking a rapid physiological response, including q_E type quenching and increased CO_2 fixation activity (Demmig-Adams and Adams, 1992; Niyogi, 1999; Li et al., 2009), will be replaced by the more long-term photoacclimation response, leading to a change in the composition of mesophyll cells in terms of their proteins, lipids, pigments, and other cofactors involved in electron transport and reactive-oxygen species metabolism (Bailey et al., 2004; Walters, 2005). This photosynthetic acclimation response involves alterations in photosynthetic

protein structures, and is thought to stay active over days (Walters, 2005). However, our study shows that gene expression levels the next day early morning (25 hours after increased irradiance) correlate better with gene expressions one hour after increased irradiance (considered to be within the photoprotection response) than with gene expressions at 3.5 hours after increased irradiance (considered to be after the switch to the photoacclimation response) (Fig. 1B). This suggests that the diurnal rhythm has more effect on plant gene expression than the effect of the increased irradiance. This effect of diurnal rhythms on photosynthetic gene expression can be explained by the importance of the interaction of the increased irradiance with the increased temperature. The light onset in the morning is followed by a temperature increase, causing the reappearance of differentially expressed heat responsive genes to re-occur on several mornings after the increased growth irradiance (Fig. 5B).

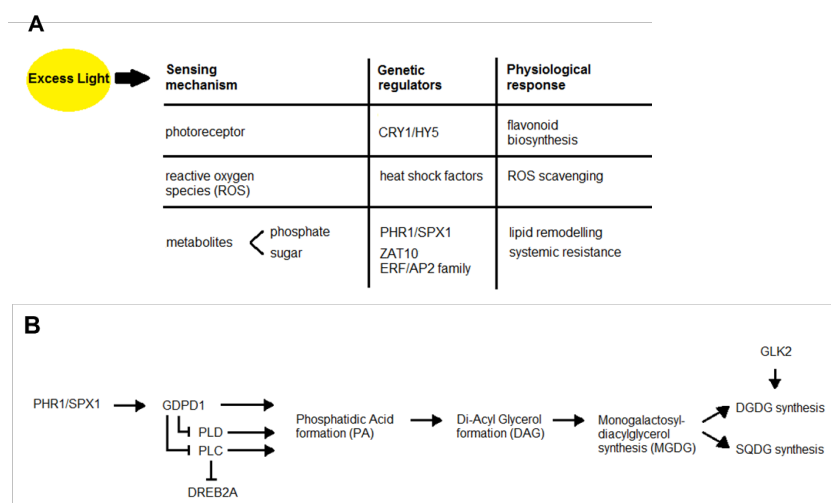

Figure 7. Model summarizing (A) the signal transduction pathways leading to transcriptional responses upon increased irradiance; and (B) the signal transduction pathway leading to phosphate deficiency dependent lipid remodelling, for which several genes were found to be up-regulated in response to increased irradiance.

CRY1 = CRYPTOCHROME 1; HY5 = LONG HYPOCOTYL 5; PHR1 = PHOSPHATE STARVATION RESPONSE 1; ZAT10 = SALT TOLERANCE ZINC FINGER 10; ERF/AP2 = ETHYLENE RESPONSE FACTOR/ APETALA2; SPX1 = SYG1, PHO81, AND XPR1 HOMOLOGUE 1; GDPD1 = GLYCEROPHOSPHO-DIESTER-PHOSPHO-DIESTERASE1; PLD = PHOSPHOLIPASE D; PLC = PHOSPHOLIPASE C; DREB2A = DEHYDRATION RESPONSE ELEMENT BINDING PROTEIN 2A; DGDG = DIGALACTOSYL DIACYLGLYCEROL; SQDG = SULFOQUINOVOSYL DIACYLGLYCEROL; GLK2 = GOLDEN-LIKE 2

From 3.5 h after the irradiance increase transcripts involved in RNA-binding are upregulated (Fig. 5), which will contribute to *de novo* protein synthesis, and is in line with the expression of new proteins as part of the acclimation response (Walters, 2005). Two genes regulating alternative splicing of many downstream RNAs are known to be up-regulated already within one hour after increased irradiance (*SERINE/ARGININE-RICH PROTEIN 45a* and *30 [SR45a and SR30]*) (Rossel et al., 2002; Tanabe et al., 2007). The observation that *SR45a* and *SR30* are up-regulated within one hour after increased irradiance suggests these genes are important regulators initiating a translational response of many genes that are induced in response to increase irradiance after 3.5 hours by alternatively splicing the mRNAs of these genes. In addition to the induced expression of many RNA-binding genes 3.5 h after the irradiance increase, these alternative splicing events contribute to the synthesis of new proteins, being part of the acclimation response (Walters, 2005). In our study, both *SR45a* and *SR30* are classified as core responsive genes, meaning they were responsive in all accessions and all time-points (Fig. 3B), although the subsequent qRT-PCR experiments showed there is some variation in the level of expression depending on accession and time-point (Fig. 4B, 5B, 6A, and 6B). *SR45a* was less up-regulated after a temperature increase compared to irradiance increase, the accession-specific effect was lost after temperature increase, and the increase in *SR45a* transcript was most obvious in the first hour after the irradiance increase (Fig. 6A and 6B), although both genes are up-regulated in increased irradiance conditions compared to control conditions also after 3.5 hours and after 25 hours (Fig. 5, 6A, and 6B). By regulating alternative splicing of many downstream genes, *SR45a* is an important regulator of the high light response. In an *sr45a* null mutant over 200 genes involved in signal transduction, regulation of transcription, protein turn-over and cell cycle regulation are altered in expression, with at least 10 of them through differences in alternative splicing (Yoshimura et al., 2011). *SR30* has not been investigated in great detail yet, but the similarity in gene expression profile (Fig 6B) and the similarity in subcellular localization (Mori et al., 2012) suggests a similar biological function as for *SR45a*. Its early activation and its involvement in the regulation of expression of many transcriptional activators make it likely that *SR45a* (and possibly also *SR30*) initiates a gene responsive pathway activating photosynthetic acclimation in response to increased irradiance.

Photoreceptor response

Three types of photoreceptors are known to be involved in the response to increased irradiance: cryptochrome (CRY), phytochrome (PHY), and phototropin (PHOT), (Li et al.,

2009). The CRY1 photoreceptor is known to regulate a large number of genes in response to increased irradiance through the HY5 transcription factor (Kleine et al., 2007). *CRY*, *PHY*, or *PHOT* were not induced in any of the three accessions upon increased irradiance; nor did we see any induced transcription of *HY5*, suggesting regulation at the protein level. However, accession-specific increase in expression of two down-stream targets of HY5 was found (Fig. 4B), and a homologue of HY5 (*HY5 HOMOLOGUE [HYH]*) was found to be time-point-specific responsive (Fig. 5B). The function of HYH partially overlaps with that of HY5, and the accumulation of the HYH protein depends on the expression of HY5 (Holm et al., 2002). The increased expression of HYH together with two down-stream targets of HY5 confirms the involvement of the CRY1/HY5 response pathway. Two phytochrome signalling genes were down-regulated, one of which is *PHYTOCHROME KINASE SUBSTRATE 4 (PKS4)*, a phytochrome signalling component involved in phototropism, phosphorylated in a PHOT1-dependent manner (Demarsy et al., 2012); the other a phytochrome kinase substrate-related protein with unknown molecular function (Fig. 5B). Together, these suggest a phytochrome-receptor response to increased irradiance mediating a phototropism response, not directly related to photosynthesis efficiency response.

Biochemical response

Two major biochemical signals are known to be responsive to increased irradiance, a pH-change within the chloroplast across the thylakoid membrane beginning within milliseconds after the induction of the irradiance increase (proton gradient dependent regulation) and redox signals mediated via changes in the degree of thioredoxin reduction, the degree of plastoquinone reduction and increased formation of ROS (redox-dependent regulation). The redox changes are a result from combined irradiance- and temperature increases (Apel and Hirt, 2004). This combined irradiance and temperature effect causes activation of heat shock proteins and heat shock factors, initiating photosynthetic acclimation responses (Jung et al., 2013).

Using heat filters to block infrared light and thus reduce the heating effect that often accompanies and irradiance increase (Rossel et al., 2002), or by running parallel experiments with light and temperature increases and a temperature increase with no irradiance increase (as done in this study), it is possible to separate of the acclimation responses of an irradiance increase from those due to a temperature increase. We found most pronounced expression induction in response to increased irradiance of several genes encoding heat shock proteins and/or heat shock factors (Fig. 3), of which

some were accession-specifically (Fig. 4) and some time-point-specifically induced (Fig. 5). The expression of heat shock genes was least induced in Ts-1 (Fig. 4B), an observation that is in line with its observed low photosynthetic efficiency response to excess irradiance (Fig. 1A).

qRT-PCR confirmed the accession-specific expression response of *HSFA2* (Fig. 6D), a gene known to be associated with photosynthesis acclimation through the ascorbate peroxidase pathway (Jung et al., 2013) and the expression of *HOP3* (Fig. 6E). *HOP3* is known to assist in undamaged import of photosynthetic pre-proteins synthesized outside the chloroplast by interacting with HSP70 and HSP90 (Fellerer et al., 2011). Both *HSFA2* and *HOP3* were induced in Ga-0 and Col-0, but not Ts-1, again in line with the differences found in photosynthesis efficiency measurements for these accessions (Fig. 1A).

Metabolite response

Response to changed metabolite levels resulting from increased irradiance levels are sensed and signalled by the ERF/AP2 transcription factor family (Moore et al., 2014; Vogel et al., 2014). Members of this family showed transcriptional response to increased irradiance (Fig. 3, 4, and 5). The ERF/AP2 transcription factors are induced by *ZAT10*, a transcription factor activated by a MAP kinase (Nguyen et al., 2012; Vogel et al., 2014). *ZAT10* was found to be transcriptionally up-regulated in this study (Fig. 5B). *ZAT10* has been reported to initiate a systemic acclimation response to excess light (Rossel et al., 2007; Munekage et al., 2015).

One regulatory gene that was characterized before to be responsive to increased irradiance is *SPX1* (Rossel et al., 2002). *SPX1*, so-called because it shares a domain with the yeast proteins Syg1 and Pho81, and the human protein Xpr1, is a phosphate-dependent inhibitor of the transcription factor PHOSPHATE STARVATION RESPONSE 1 (PHR1), (Puga et al., 2014). The physical interaction between *SPX1* and PHR1 is reduced in the absence of inorganic phosphate (Pi), leading to transcription of many Pi starvation induced genes by PHR1 (Bustos et al., 2010; Puga et al., 2014). Among these PHR1-induced genes is *SPX1*, but the *SPX1* protein is unable to bind PHR1 until Pi becomes available again (Puga et al., 2014). In this study, *SPX1* was up-regulated in Col-0 and to a lesser extent in Ga-0 (but not Ts-1) one hour after the irradiance increase, (Fig. 6G). It was also found to be specifically responsive to irradiance increase and not to temperature increase (Fig. 6G). This agrees with Rossel et al (2002) who found that *SPX1* was specifically induced by one hour fHL (filtered for the heat-producing infrared).

Therefore, we conclude that SPX1, acting in concert with PHR1, rapidly initiates a pathway of increased irradiance responsive genes that is independent of heat shock, and is associated with natural variation in photosynthesis efficiency acclimation (Fig. 1A). Expression of *PHR1* was not responsive to increased irradiance; probably because *PHR1* transcription levels are kept stable by SPX1. Besides *SPX1*, the genes *GLK2*, *GDPD1* and *DREB2A* were found to be accession-specifically induced in response to increased irradiance independent of heat shock (Fig. 6). The next paragraph describes how these three genes connect to lipid remodelling, summarized in Fig. 7B.

Phosphate-deficiency-dependent lipid remodelling response

Several lipid remodelling genes are activated one hour after the irradiance increase, mainly in Col-0 (Fig. 4 and 5). Increased irradiance induces a condition where more phosphate is required for additional photosynthesis structures and where photosynthetically produced sugars are in excess. An interaction between phosphate and sugar metabolism is known to exist on the transcriptional level (Müller et al., 2007); several genes involved in galactolipid biosynthesis were up-regulated in response to combined phosphate starvation and sugar accumulation (Müller et al., 2007). The interaction between phosphate and sugar metabolism was hypothesized to be important for either (1) maintenance of the ratio of available Pi and carbon by reducing the cellular sucrose content via galactolipid synthesis; or (2) supply of galactolipids as components of the plasma membrane to support enhance growth under sucrose supplementation (Murakawa et al., 2014). Our study supports this hypothesis, as both phosphate-deficiency-initiated lipid remodelling genes as well as carbohydrate (sucrose) metabolism genes were found to be light-responsive (Fig. 4 and 5).

Compared to Ga-0 and Ts-1, there is enhanced expression in Col-0 of several genes involved in galactolipid biosynthesis (Fig. 4 and Table S3) and reduced expression of one particular gene (*GOLDEN2-LIKE2* [*GLK2*], Table S4). Golden2-like transcription factors (GLK) are required for chloroplast development by regulating genes involved in chlorophyll biosynthesis (Waters et al., 2009). *GLK2* was shown to be a pivotal regulator of *DGD1*, which encodes for the key enzyme of di-galactosyl-diacyl-glycerol (DGDG) synthesis (Kobayashi et al., 2014). DGDG is a bilayer-forming galactolipid, important for the integrity of the chloroplast protein-import apparatus (Chen and Li, 1998). In addition, DGDG replaces phospholipids in several organelles and membranes in phosphate-limited conditions (Härtel et al., 2000). *GLK2* expression was repressed in Col-0 and Ga-0 (but not Ts-1) one hour after increased irradiance, and activated in Col-0 and Ga-0 (but not

Ts-1) 3.5 hours after increased irradiance (Fig. 6C). Additionally, it was found to be specifically responsive to light increase (and not to temperature increase; Fig. 6C). This expression pattern implies that GLK2-induced DGDG replacement of phospholipids is activated only after 3.5 hours of excess light.

Three metabolic pathways are known for the release of Pi from phospholipids during Pi deficiency (Ruelland et al., 2015), two of which – galactolipid formation through the generation of phosphatidic acid (PA) by phospholipase C (first route) or, alternatively, phospholipase D (second route) – are extensively studied (Gaude et al., 2008; Nakamura et al., 2009). *GLYCEROPHOSPHO-DIESTER-PHOSPHO-DIESTERASE1* (*GDPD1*) is another gene known to respond to phosphate limitation that was found up-regulated upon increased irradiance (Fig. 4B and 5B); *GDPD1* is suggested to mediate the third route for the release of Pi from phospholipids during Pi starvation (Cheng et al., 2011). In our experiment, the *GDPD1* pathway is the only of the three phosphate limitation activated pathways normally up-regulated in excess light, that is significantly higher induced in Col-0 compared to Ga-0 and Ts-1 (Fig. 6H). The promoters of the *GDPD* family were found to all include Pi response elements binding to the PHR1 transcription factor (Cheng et al., 2011). To release Pi from phospholipids, the phospholipids are catalyzed into glycerophosphodiester and then hydrolyzed into glycerol-3-phosphate (G-3-P) by *GDPD*. It is unknown how Pi is released from G-3-P in Pi starved plants, but is suggested to be released via the *de novo* pathway of DGDG and/or SQDG synthesis (Cheng et al., 2011). Through this pathway, G-3-P is first converted into phosphatidic acid (PA) and then Pi is released in the subsequent conversion of PA into di-acyl-glycerol (DAG) by phosphatidic acid phosphohydrolases (PAH), (Nakamura et al., 2009). DAG is the direct substrate for synthesis of either MGDG (by *MGD1*, *MGD2*, and *MGD3*), DGDG (by *DGD1* and *DGD2*), or SQDG (by *SQD1* and *SQD2*), where MGDG is the precursor of both end-products DGDG and SQDG. The *gdpd1* mutant did not affect DGDG content, but SQDG content was not measured (Cheng et al., 2011). In this study, *DGD1* and *DGD2* were not transcriptionally responsive to excess light, whereas *SQD1* and *SQD2* were both up-regulated, only in Col-0, comparable to *SPX1* and *GDPD1* (Fig. 4B and 5B). Therefore, this study supports the hypothesis of Cheng et al (2011) in the part of release of extra Pi needed in phosphate-limited conditions mediated through SQDG synthesis. We hypothesize that the preference of SQDG over DGDG for replacement of phospholipids for releasing extra Pi in response to excess light is explained by the fact that SQDG brings a charge balance to the photosynthetic membranes that is overcharged as a result of the excess light, as, in contrast to MGDG and DGDG, SQDG is negatively charged. We suggest this preference for SQDG is mediated by reduced DGDG synthesis as result

of decreased *GLK2* expression leading to reduced *DGD1* expression (Fig. 7B). When after ~ 3.5 hrs, the charge balance is recovered, *GLK2* transcription is induced (Fig. 6C), leading to activation of DGDG synthesis.

Besides the PHR transcription factor, we found expression of another transcription factor gene previously implicated to be responsive to increased irradiance, encoding the dehydration-responsive element binding protein *DREB2A* (Rossel et al., 2002). *DREB2A* is induced by hydrogen peroxide and is known as a key regulator of drought response, though it is known to be involved in response to heat stress (Sakuma et al., 2006). *DREB2A* belongs to the ERF/AP2-type transcription factor family, binding to drought responsive elements (DRE) in the promoters of transcriptional target genes. *DREB2A* is transcriptionally up-regulated one hour after irradiance increase, only in Col-0 (Fig. 6I), as are *SPX1* and *GDPD1*. It is known that the expression of *DREB2A* is repressed by the phosphoinositide dependent-phospholipase C (PI-PLC) pathway in basal conditions (Ruelland et al., 2013), one of the pathways for the release of Pi from phospholipids. We propose that the activation of the GDPD pathway, as a result of Pi limitation, outcompetes the PLC pathway, leading to reduced PLC-mediated repression of *DREB2A*, leading to activation of drought responsive genes, explaining the crosstalk (Fig. 7B).

Conclusion

Our gene expression analysis shows the existence of a gene activation pathway for photosynthetic acclimation to increased irradiance that starts with the *SPX1*-mediated activation of the transcription factor *PHR1* and activates the physiological process of membrane lipid remodelling (Fig. 7B). The involvement of *PHR1* for photosynthetic responses to high light has been demonstrated before (Nilsson et al., 2011); the current study adds insights into the physiological mechanism behind it. It is hypothesized to involve the replacement of phospholipids by SQDG (preferred of DGDG) for releasing extra Pi needed for photosynthetic structures and for creating a charge balance to the photosynthetic membranes that is overcharged as a result of the excess light.

In addition, we suggest a gene activation pathway that starts with the activation of the regulators *SR45a* and *SR30*, which mediate alternative splicing activities. However, the downstream targets of these regulators and their involvement with photosynthetic acclimation remain to be elucidated.

This study aimed to explain natural variation in photosynthetic acclimation to increased irradiance at the transcriptional level, for which we studied gene regulation in three

accessions. Based on the results of this study, stronger expression of heat responsive genes in the accession Ga-0 might explain its slightly higher photosynthesis efficiency compared to Col-0. The absence of induced expression of heat responsive genes in Ts-1 partly explains its lower photosynthetic efficiency. The importance of the combined light and heat shock responsive pathway to increased irradiance is well known for the scavenging of reactive oxygen species for the maintenance of proper functioning of the photosynthetic membrane. Furthermore, a new, increased irradiance responsive PHR-mediated gene activation pathway was found, acting on membrane remodelling. This pathway was active in both Ga-0 and Col-0, providing additional explanation for the higher photosynthesis efficiencies in these accessions compared to Ts-1, in which the activation of both the heat shock responsive pathway as well as the PHR-mediated pathway is absent.

ACKNOWLEDGEMENTS

We thank Dr. Wilco Ligterink for his help with analysing the microarray data. This project was carried out within the research programme of BioSolar Cells, co-financed by the Dutch Ministry of Economic Affairs.

SUPPLEMENTARY TABLES AND FIGURES

Table S1. Core genes responsive to irradiance increase; genes more than 1.4-fold up-regulated at all time points in Col-0 as well as in both Ga-0 and Ts-1 at 1 hour after light onset, when comparing plants exposed to increased irradiance to control plants.
Uniogeed fold changes are shown, green shading indicates accession-specific difference in expression present in control conditions independent of irradiance increase, orange shading indicates high light specific accession- or time-point differences. Acc. spec. = A accession-specific difference (P=0.05) when comparing Col-0, Ga-0 and Ts-1; Time spec. = Time-specific difference (P=0.05) when comparing 1, 3.5, and 25 hours; Acc. spec. in cont. = Accession-specific difference in expression present in control conditions, independent of irradiance increase; Time spec. in cont. = Time-specific difference in expression present in control conditions, independent of irradiance increase; HL spec. acc. = High light specific accession difference; HL spec. time = High light specific time-point difference

| Atg02840 | Encodes a member of the DREB8 subfamily A-6 or ERFAP2 transcription factor family. The protein contains one AP2 domain. | 2.47 | 1.69 | 1.60 | 3.02 | 1.77 | 3.02 | 1.77 | photosynthesis; response | transcription factor activity | nucleus | no | no | no | no |
| Atg050410* | Encodes the transcription factor DREB2A that specifically binds to DRE/CRT cis elements including DREB2B. The protein contains one AP2 domain. Overexpression of transcriptional activator DREB2A confers drought stress tolerance but only slight freezing tolerance in transgenic Arabidopsis plants. | 3.64 | 1.42 | 1.46 | 2.24 | 3.86 | 2.24 | 3.86 | photosynthesis; response; heat | transcription factor activity | nucleus | yes | yes | yes | yes |
| Atg07990 | Encodes a cytosolic ascorbate peroxidase APX1. Ascorbate peroxidases are enzymes that catalyze the conversion of ascorbate to ascorbyl radicals. In Arabidopsis, three cytosolic (APX1, APX2, APX3), two chloroplastic types (Stromal APX, thylakoid APX), and three microsomal (APX4, APX5, APX6) isoforms. At least part of the APX1 gene is transcribed from a second promoter that is induced by drought stress and scavenged by APX1. Expression of the gene is downregulated in the presence of paraquat, an inducer of photooxidative stress. | 1.47 | 1.68 | 1.50 | 1.59 | 1.61 | 1.59 | 1.61 | photosynthesis; response to heat | H2O2 scavenging | cytoplasm | no | no | no | no |
| Atg016050* | Encodes a protein with pyridoxal phosphate synthase activity whose transcripts were detected mostly in roots and accumulate during senescence. | 2.89 | 1.65 | 1.57 | 2.85 | 2.72 | 2.85 | 2.72 | pyridoxal phosphate biosynthesis | protein binding | cytoplasm | no | yes | no | yes |

|-----------|--|------|------|------|------|------|-----------------------|-------------------------------|-----------------------|---------------------|---------------------|---------------|---------------|
| A5294500 | One of three genes in A. thaliana encoding multiprotein bridging factor 1, a highly conserved transcriptional coactivator. May serve as a bridging factor between a bZIP factor and TBP. Its expression is induced by salicylic acid, jasmonic acid, ethylene, and abscisic acid. It is involved in hydrogen peroxide, and application of abscisic acid or salicylic acid. Constitutive expression enhances the tolerance of transgenic plants to various biotic and abiotic stresses. | 2.55 | 1.84 | 1.72 | 2.46 | 2.73 | unknown | transcription factor activity | nucleus | no | yes | | |
| A5591484 | Encodes bZIP protein; FUNCTIONS IN: DNA binding, sequence-specific DNA binding transcription factor activity; INVOLVED IN: regulation of transcription, DNA dependent | 2.44 | 1.52 | 1.56 | 2.39 | 2.13 | unknown | transcription factor activity | nucleus | no | yes | | yes |
| A5593930 | Encodes ATP-BINDING CASSETTE F2 (ABC F2), member of GCN subfamily | 1.91 | 2.03 | 1.53 | 1.51 | 1.61 | unknown | transporter | plasma membrane | yes | no | | |
| A11907500 | Unknown protein | 3.43 | 2.47 | 3.25 | 2.18 | 1.80 | unknown | unknown | nucleus | no | no | | yes |
| A11921550 | Calcium-binding EF-hand family protein | 5.07 | 1.57 | 2.02 | 2.87 | 2.78 | unknown | unknown | cytoplasm | yes | no | yes | yes |
| A3324750 | Unknown protein | 1.84 | 2.68 | 4.22 | 1.74 | 1.90 | unknown | unknown | nucleus | no | no | | yes |
| A33251238 | Potential natural antisense gene, locus overlaps with AT3G51240 | 1.61 | 2.53 | 1.74 | 1.46 | 2.03 | unknown | unknown | unknown | yes | no | | yes |
| A4918422 | Unknown protein | 2.37 | 1.44 | 1.69 | 1.90 | 1.59 | unknown | unknown | mitochondria | no | no | | yes |
| A4926888 | Upstream open reading frames (ORFs) are small open reading frames found in the 5' UTR of a mature mRNA, and can potentially modulate translational regulation of the largest, or major, ORF (mORF). CDSORF49 represents a conserved upstream opening reading frame relative to major ORF CDSORF41. | 2.60 | 1.66 | 1.74 | 1.91 | 1.97 | unknown | unknown | mitochondria | no | yes | | yes |
| A55913890 | Unknown protein | 1.44 | 1.57 | 1.76 | 2.38 | 1.58 | unknown | unknown | nucleus | no | no | | no |

Table S2 Core genes responsive to irradiance increase; genes more than 1.4-fold down-regulated in all time points in Col-0 as well as in both Ga-0 and Ts-1 at 1 hour after light onset, when comparing plants exposed to increased irradiance to control plants.

Unlogged fold changes are shown, green shading indicates accession-specific difference in expression present in control conditions independent of irradiance increase, orange shading indicates high light specific accession- or time-point differences. Acc. spec. = Accession-specific difference ($P=0.05$) when comparing Col-0, Ga-0 and Ts-1; Time spec. = Time-specific difference ($P=0.05$) when comparing 1, 3.5, and 25 hours; Acc. spec. in cont. = Accession-specific difference in expression present in control conditions, independent of irradiance increase; Time spec. in cont. = Time-specific difference in expression present in control conditions, independent of irradiance increase; HL spec. acc. = High light specific accession difference; HL spec. time = High light specific time-point difference.

|-----------|--|------|-------|------|------|------|----------------------------------|-------------------------------|-----------------------|------------|------------|---------------------|---------------------|---------------|---------------|
| At3g22170 | Encodes GUS1/2 (GUS1, GUS2). Both genes help promote activity in the leaf-vein direction. The LINC2 homologous LINC2 (At5g15800) has similar function. | 0.52 | 0.47 | 0.50 | 0.50 | 0.56 | cell elongation and biogenesis | protein binding | nucleus | no | no | no | no | | |
| At5g44680 | DNA topoisomerase specifically inhibits: FUNCTIONS N: DNA 5-methyladenine glycosylase 1 activity, DNA topoisomerase activity, INVOLVED IN: DNA repair, base-excision repair, DNA topoisomerase activity, INVOLVED IN: DNA repair, base-excision repair, auxin levels in a time-of-day, specific manner. | 0.58 | 0.40 | 0.51 | 0.65 | 0.66 | DNA repair | hydrolase activity | nucleus | no | yes | no | yes | | |
| At5g17300 | Multiple transcription factors (NICE1, IRISQUELLE1) that regulates hypocotyl growth by regulating free auxin levels in a time-of-day, specific manner. | 0.45 | 0.70 | 0.50 | 0.47 | 0.33 | hypocotyl growth | transcription factor activity | nucleus | no | yes | no | yes | | |
| At1g71030 | Encodes a nuclear, myb family, transcription factor, MYB_LIKE_2 (MYBL2). It is related to other other myb-like proteins. Its myb domain consists of a single repeat. A proline-rich region potentially involved in transactivation is found in the C-terminal part of the protein. Its transcript accumulates mainly in leaves. | 0.52 | 0.27 | 0.52 | 0.31 | 0.36 | leaf morphology | transcription factor activity | nucleus | yes | yes | yes | yes | | |
| At5g46460 | Bifunctional inhibitor/lipid transfer protein/seed storage 2S albumin superfamily protein; FUNCTIONS N: lipid binding; INVOLVED IN: lipid transport | 0.38 | 0.17 | 0.23 | 0.43 | 0.40 | lipid transport | lipid binding | extracellular | no | yes | no | no | | yes |
| At5g20110 | Durin light chain type 1 family protein; FUNCTIONS N: microtubule motor activity; INVOLVED IN: microtubule-based process | 0.56 | 0.64 | 0.55 | 0.56 | 0.63 | microtubule motor activity | hydrolase activity | cytoplasm | no | no | no | no | | |
| At5g19170 | Chloroplast large/germ member of a family of enzymes similar to iron-cis-epoxyketonoid dioxygenase | 0.43 | 0.29 | 0.18 | 0.56 | 0.45 | oxidation-reduction process | protein binding | chloroplast | no | yes | yes | no | | yes |
| At5g44190 | Encodes GLK2, Golden2-like 2, one of a pair of partially redundant nuclear transcription factors that regulate chloroplast development in a cell-autonomous manner. GLK1, Golden2-like 1, is encoded by At2g02070. GLK1 and GLK2 regulate the expression of the photosynthetic apparatus. | 0.54 | 0.60 | 0.36 | 0.58 | 0.53 | photosynthesis | transcription factor activity | nucleus | no | yes | no | no | | yes |
| At5g07580 | Encodes a member of the ERF (ethylene response factor) subfamily B-3 of ERF/AP2 transcription factor family. The protein contains one AP2 domain. There are 18 members in this subfamily including ATERF-1, ATERF-2, AND ATERF-5. | 0.67 | 0.56 | 0.60 | 0.55 | 0.58 | photosynthesis; drought response | transcription factor activity | nucleus | no | no | no | no | | |
| At5g25190 | Encodes a member of the ERF (ethylene response factor) subfamily B-6 of ERF/AP2 transcription factor family. The protein contains one AP2 domain. There are 12 members in this subfamily including RMZ1.1. | 0.54 | 0.32 | 0.50 | 0.56 | 0.65 | photosynthesis; drought response | transcription factor activity | nucleus | no | yes | no | no | | yes |
| At1g91900 | Phototropin-responsive NPH3 family protein; FUNCTIONS N: signal transducer activity; INVOLVED IN: response to light stimulus | 0.63 | 0.47 | 0.55 | 0.58 | 0.56 | protein ubiquitination | signal transducer activity | plasma membrane | no | no | no | no | | |
| At1g93300 | Encodes G1L2-LIKE 1 (G1L1); a plant transcription factor that contains two separate, but similar, trihex DNA-binding domains, similar to G1L2. Gene is expressed in all aerial parts of the plant, with higher level of expression in siliques. AtG1L2 was thought to be a duplicated copy of the gene but is likely to be a cloning artifact, the result of a chimeric clone. | 0.46 | 0.47 | 0.42 | 0.48 | 0.60 | trichome morphogenesis | transcription factor activity | nucleus | no | no | no | no | | |
| At2g01024 | In a tandem repeat with AT2g35432 (TCL1) and AT2g35420 (ETC2), it encodes a single repeat R3 MYB transcription factor that is involved in the negative regulation of trichome formation. | 0.44 | 0.52 | 0.47 | 0.64 | 0.68 | trichome morphogenesis | transcription factor activity | nucleus | no | no | no | no | | |

| A1927070 | Encodes PHOSPHOMANNANOSE ISOMERASE 2 (PM2), also known as DARK INDUCED 9 (DIN9) a protein with phosphomannose isomerase activity that is involved in synthesis of ascorbic acid. Expression is induced after 24 hours of dark treatment in Arabidopsis thaliana. The gene is expressed specifically in tissues undergoing secondary wall thickening. This is a member of glycosyl hydrolase family 3 and has six other closely related members. | 1.37 | 1.16 | 2.01 | carbohydrate metabolism | mannose-6-phosphate isomerase activity | Cytoplasm | no |
| A15243360 | Encodes a bifunctional (beta-D-xylosidase) (alpha-L-arabinofuranosidase) required for pectic arabinan modification. Located in the extracellular matrix. Gene is expressed specifically in tissues undergoing secondary wall thickening. This is a member of glycosyl hydrolase family 3 and has six other closely related members. | 1.05 | 1.07 | 1.72 | carbohydrate metabolism | pectic arabinan modification | extracellular | yes |
| A1978820 | D-mannose binding lectin protein with Apple-like catohydrase-binding domain; FUNCTIONS IN: sugar binding | 0.92 | 0.92 | 1.44 | carbohydrate metabolism | sugar binding | plasma membrane | no |
| A1956650 | Encodes PRODUCTION OF ANTHOCYANIN PIGMENT 1 (PAP1), a putative MYB domain containing transcription factor involved in anthocyanin metabolism and radical scavenging. Essential for the sucrose-mediated expression of the chloroplast redox genes. Arab and ethylene responsiveness of PAP1 transcription is lost in myp12 mutants. | 3.12 | 1.12 | 0.77 | carbohydrate metabolism | transcription factor | nucleus | yes |
| A2911270 | Citrate synthase-related; FUNCTIONS IN: transference activity, transferring acyl groups, acyl groups converted into acyl on transfer INVOLVED IN: cellular carbohydrate metabolic process | 1.44 | 0.88 | 1.03 | carbohydrate metabolism | transference activity | mitochondria | yes |
| A15267100 | Nucleotide:sugar transporter family protein | 1.46 | 1.58 | 0.97 | carbohydrate metabolism | transport | membrane | no |
| A14237180 | Myb family transcription factor, contains Pfam domain, PR02049: Myb-like DNA-binding domain, also isolated as a putative cytoskeletal protein in a yeast screen | 1.52 | 1.50 | 0.99 | cell organization and biogenesis | transcription factor activity | nucleus | no |
| A1958840 | Encodes a peroxisomal polyamine oxidase PAOX, involved in the back-conversion polyamine degradation pathway. | 1.08 | 1.08 | 1.60 | cellular amino acid metabolism | polyamine degradation | nucleus | no |
| A15253970 | Encodes tyrosine aminotransferase which is strongly induced upon aging and coronatine treatment | 1.22 | 1.03 | 1.69 | cellular amino acid metabolism | transference activity | cytoplasm | no |
| A2903240 | EXS (ERD1XPR1S1G1) family protein | 0.96 | 1.24 | 1.48 | cellular response to abiotic stress | unknown | plasma membrane | no |
| A1424010 | Encodes a protein similar to cellulose synthase | 1.48 | 0.80 | 0.91 | cellulose biosynthesis | cellulose synthase | plasma membrane | yes |
| A1426150 | Encodes a member of the GATA factor family of zinc finger transcription factors. Modulate chlorophyll biosynthesis and glutamate synthase (GLU1F-GOAT) expression. | 0.77 | 1.23 | 1.42 | chlorophyll biosynthesis | transcription factor activity | nucleus | yes |
| A1954770 | Tetratricopeptide repeat (TPR)-like superfamily protein | 0.74 | 0.77 | 1.45 | chloroplast organization | unknown | nucleus | yes |
| A15259220 | Highly ABA-induced PP2C gene 1 (HA1); FUNCTIONS IN: protein serine/threonine phosphatase activity, catalytic activity; INVOLVED IN: response to water deprivation, response to abiotic acid stimulus; LOCATED IN: chloroplast | 3.53 | 2.42 | 1.37 | chloroplast organization; stomatal movement | phosphatase activity | cytoplasm | yes |

| Gene ID | Gene name and description | C-1 | G-1 | T-1 | GO Biological Process | GO Molecular Function | GO Cellular Component | Acc. spec. in cont. |
|-----------|--|------|------|------|-----------------------------|-------------------------------|-----------------------|---------------------|
| A0221130 | Cyclophilin-like peptidyl-prolyl cis-trans isomerase family protein | 1.75 | 1.40 | 1.07 | circadian rhythm | protein binding | cytoplasm | yes |
| A1568090 | Disease resistance protein (TR-NBS class); FUNCTIONS IN: transmembrane receptor activity, nucleoside-5'-triphosphatase activity, nucleotide binding, ATP binding | 2.37 | 1.21 | 0.95 | defense response | kinase activity | chloroplast | no |
| A4623310 | Encodes a cytoskeletal receptor-like protein kinase. | 0.95 | 1.07 | 1.44 | defense response | kinase activity | extracellular | no |
| A4603980 | Encodes an atypical dual-specificity phosphatase involved in the negative regulation of defense response to a bacterial pathogen, P. syringae pv. tomato. | 2.27 | 1.36 | 1.60 | defense response | MAP kinase activity | cytoplasm | no |
| A3191970 | CYP707M4. Encodes a cytochrome P450 protein with ABA 8-hydroxylase activity, involved in ABA catabolism. | 1.89 | 1.45 | 1.09 | electron transport | ABA catabolism | extracellular | no |
| A31914620 | Purative cytochrome P450 (CYP72A8). | 2.02 | 0.80 | 0.74 | electron transport | unknown | unknown | no |
| A0283830 | LIPID TRANSFER PROTEIN 2 (LTP2); involved in lipid transfer between membranes. Belongs to a family of Lipid Transfer proteins. | 2.05 | 0.79 | 0.47 | lipid remodeling | lipid transfer | golgi; extracellular | no |
| A02911810 | MONOGALACTOSYLGLYCEROL SYNTHASE 3 (MGDS3); MGDS3 is the major enzyme for galactolipid metabolism during phosphate starvation. Does not contribute to galactolipid synthesis under P-sufficient conditions. | 1.64 | 1.04 | 1.05 | lipid remodeling | MGDS biosynthesis | chloroplast | no |
| A0520410 | MONOGALACTOSYLGLYCEROL SYNTHASE 2 (MGDS2). Encodes a type B monogalactosylglycerol (MGDG) synthase under P-sufficient conditions. Does not contribute to galactolipid synthesis under P-sufficient conditions but does under P starvation. | 2.22 | 1.18 | 1.68 | lipid remodeling | MGDG biosynthesis | chloroplast | no |
| A31917790 | PURPLE ACID PHOSPHATASE 17 (PAP17); Expression is upregulated in the shoot of cax1/cax3 mutant. | 2.91 | 1.64 | 1.40 | lipid remodeling | phosphatase activity | extracellular | no |
| A3192040 | Encodes a member of the glycerophosphodiester phosphodiesterase (GDPD) family. Has glycerophosphodiester phosphodiesterase activity. Functions in maintaining cellular phosphate homeostasis under phosphate starvation. | 6.54 | 2.26 | 2.98 | lipid remodeling | phospholipid catabolism | cytoplasm | yes |
| A4633030 | SQD1, involved in sulfolipid biosynthesis | 2.31 | 1.41 | 1.63 | lipid remodeling | SQDG biosynthesis | chloroplast | no |
| A4591220 | SQD2, involved in sulfolipid biosynthesis | 2.32 | 1.14 | 1.45 | lipid remodeling | SQDG biosynthesis | chloroplast | no |
| A0228660 | SPX domain gene 2 (SPX2) | 1.85 | 1.18 | 1.47 | lipid remodeling | unknown | nucleus | no |
| A43633790 | AtMyb in repeat family protein / regulator of chromosome condensation (RCC) family protein | 1.50 | 1.04 | 1.16 | lipid remodeling | unknown | nucleus | no |
| A0520150 | SPX DOMAIN GENE 1 (SPX1); Expression is upregulated in the shoot of cax1/cax3 mutant. | 4.30 | 1.29 | 1.97 | lipid remodeling | unknown | nucleus | yes |
| A43603990 | METALLOTHIONEIN 2A (MT2A); binds to and detoxifies excess copper and other metals, limiting oxidative damage | 1.39 | 1.00 | 0.92 | metal ion binding | copper detoxification | unknown | no |
| A0291040 | S-adenosyl-L-methionine-dependent methyltransferases superfamily protein | 1.57 | 1.40 | 2.48 | methylsation | methyltransferase activity | chloroplast | no |
| A43621070 | Encodes a protein with NAAD(H) kinase activity. | 1.48 | 1.17 | 1.71 | NAD metabolic process | NAD+ kinase activity | cytoplasm | no |
| A4620820 | FAD-binding Benzene family protein; FUNCTIONS IN: electron carrier activity, oxidoreductase activity, FAD binding, catalytic activity, INVOLVED IN: oxidation reduction | 0.86 | 0.74 | 1.46 | oxidation-reduction process | electron transport | chloroplast | no |
| A0222240 | Myo-inositol 1-phosphatase isozyme 2 (MIPS2). E expressed in leaf, root and silique. Immunolocalization experiments with an antibody recognizing MIPS1, MIPS2, and MIPS3 showed endoplasmic localization. | 1.64 | 1.27 | 0.93 | phospholipid biosynthesis | choryphyl catabolic process | cytoplasm | no |
| A1522830 | INDOLE-3-ACETIC ACID 6 (IA6); an exogenous dominant suppressor of the hy2 mutant phenotype. Also exhibits aspects of constitutive photomorphogenic phenotype in the absence of hy2. | 1.15 | 1.40 | 2.00 | photomorphogenesis | transcription factor activity | nucleus | no |
| A45623730 | Encodes REPRESSOR OF UV-B PHOTOMORPHOGENESIS 2 (RUP2). Functions as a repressor of UV-B signaling. | 1.04 | 1.12 | 1.57 | photoreceptor activity | photoreceptor organization | cytoplasm | no |

| Gene ID | Gene name and description | C-1 | G-1 | T-1 | GO Biological Process | GO Molecular Function | GO Cellular Component | Acc. spec. in cont. |
|-----------|--|-------|------|------|--|--|-----------------------|---------------------|
| A1562220 | Encodes REPRESSOR OF UV-B PHOTOMORPHOGENESIS 1 (RUP1), a transcription protein whose gene expression is induced by UV-B. This induction is reduced in the <i>hy5</i> mutant and may be a target of HY5 during UV-B response. Functions as a repressor of UV-B signaling. | 1.37 | 1.38 | 2.22 | photoreceptor activity | chromatid organization | chromoplast | no |
| A1564020 | Fibrillin precursor protein. The fibrillin precursor, but not the mature protein interacts with AB2. Regulated by abscisic acid response regulators. Involved in abscisic acid-mediated photoprotection. | 2.26 | 2.94 | 0.95 | photosynthesis | photoprotection | chloroplast | yes |
| A15620880 | Encodes ERF53, a drought-induced transcription factor. Belongs to the AP2/ERF superfamily, and has a highly conserved AP2 domain. Regulates drought-responsive gene expressions by binding to the GCC box and/or dehydration-responsive element (DRE) in the promoter of downstream genes. | 2.84 | 2.50 | 1.68 | photosynthesis; response to drought | transcription factor activity | nucleus | no |
| A15656410 | Encodes DREB2A, a transcription factor that specifically binds to DRE/CRT cis elements (responsive to drought and low-temperature stress). Belongs to the DREB subfamily A-2 of ERF/AP2 transcription factor family (DREB2A). | 3.64 | 2.24 | 3.96 | photosynthesis; response to drought | transcription factor activity | nucleus | no |
| A11516420 | Encodes MCB, a methyltransferase (cytochrome P450-dependent) that is involved in promoting programmed cell death in response to hydrogen peroxide (H2O2), UV light, and methylviologen (MV). | 1.07 | 1.16 | 1.94 | response to abscisic acid; programmed cell death | cytochrome P450 endoperoxidase | unknown | no |
| A15643190 | Galactose oxidase/ferlin repeat superfamily protein | 1.05 | 0.98 | 1.45 | protein catabolism | ubiquitin-protein transferase activity | nucleus | no |
| A11562710 | Encodes a vacuolar processing enzyme belonging to a novel group of cyclase proteases that is expressed specifically in seeds and is essential for the proper processing of storage proteins. | 1.44 | 0.89 | 0.95 | protein storage | hydrolase activity | unknown | no |
| A15628590 | Phosphoglycerate mutase, 2,3-bisphosphoglycerate-independent:FUNCTIONS IN: manganese ion binding, phosphoglycerate mutase activity, 2,3-bisphosphoglycerate-independent phosphoglycerate mutase activity, catalytic activity, metal ion binding | 1.49 | 1.35 | 1.11 | response to cadmium ion | glucose catabolic process | cytoplasm | no |
| A11563880 | Encodes glutathione transferase GSTU28 belonging to the tau class of GSTs. | 2.87 | 2.69 | 4.76 | response to cadmium ion | glutathione transferase | cytoplasm | no |
| A11565980 | Thioredoxin-dependent peroxidase 1 (TPX1) | 1.45 | 0.74 | 0.98 | response to cadmium ion | peroxidase | cytoplasm | no |
| A15646340 | A member of Arabidopsis BAG (BCL-2-associated atrogenic) proteins, plant homologs of mammalian regulators of apoptosis. Expression of BAG6 in leaves was strongly induced by heat stress | 7.26 | 9.31 | 4.27 | response to heat | chaperone | nucleus | no |
| A15613470 | Encodes a subunit of chaperonins CHAPERONIN-6/BETA2 (CPN6/BETA2) that are involved in mediating the folding of newly synthesized, translocated, or stress-denatured proteins. | 2.02 | 2.20 | 1.40 | response to heat | chaperone | chloroplast | no |
| A15621670 | HSP20-like chaperones superfamily protein | 4.25 | 4.54 | 2.61 | response to heat | chaperone | cytoplasm | no |
| A15643260 | Chaperone protein dnaJ-related | 1.21 | 0.95 | 1.62 | response to heat | chaperone | chloroplast | no |
| A15651440 | HSP20-like chaperones superfamily protein | 7.07 | 6.57 | 3.97 | response to heat | chaperone | mitochondria | no |
| A11563070 | Agglutinin-promoting Bax ribonuclease-1 family protein | 4.02 | 1.58 | 1.19 | response to heat | glutamate binding | unknown | no |
| A11563540 | HSP20-like chaperones superfamily protein | 8.12 | 7.41 | 3.23 | response to heat | heat shock protein | cytoplasm | no |
| A11571000 | Chaperone DnaJ-domain superfamily protein;FUNCTIONS IN: heat shock protein binding | 3.91 | 3.43 | 1.94 | response to heat | heat shock protein | cytoplasm | no |
| A1562120 | Heat-shock protein 70T.2 (HSP70T.2) | 2.60 | 3.37 | 2.02 | response to heat | heat shock protein | cytoplasm | no |
| A15638970 | J domain protein localized in ER lumen, shows similarity to HSP40 proteins and is induced by heat stress. | 4.69 | 4.32 | 3.08 | response to heat | heat shock protein | endoplasmic reticulum | no |
| A15646230 | HEAT SHOCK PROTEIN 17.4 (HSP17.4) | 10.13 | 7.49 | 4.88 | response to heat | heat shock protein | cytoplasm | no |
| A15612400 | Hsp3, one of the 36 carboxy-terminal clamp (CC)-tail atropicopeptide repeat (TPR) proteins with potential to interact with Hsp60/Hsp70 as co-chaperones. | 9.12 | 5.02 | 4.13 | response to heat | heat shock protein | unknown | yes |

| Gene ID | Gene name and description | C-1 | G-1 | T-1 | GO Biological Process | GO Molecular Function | GO Cellular Component | Acc. spec. in cont. |
|-----------|--|------|------|------|--|-------------------------------|-----------------------|---------------------|
| A1961320 | Encodes heat stress-associated 32-kD protein. Up-regulated by heat shock. Thermotolerance in a knockout mutant was compromised following a long recovery period (> 24 h) after acclimation heat shock treatment. | 2.29 | 2.69 | 1.72 | response to heat | heat shock protein | nucleus | no |
| A1965200 | MITOCHONDRION-LOCALIZED SMALL HEAT SHOCK PROTEIN 23.6 (HSP23.6-MITO) | 5.64 | 8.13 | 3.93 | response to heat | heat shock protein | mitochondria | no |
| A1969590 | Heat shock protein 70 (HSP70-5) | 2.90 | 2.66 | 1.66 | response to heat | heat shock protein | mitochondria | no |
| A1969600 | HEAT SHOCK PROTEIN 81.2 (HSP81.2), a member of heat shock protein 90 (HSP90) gene family | 2.05 | 1.25 | 2.27 | response to heat | heat shock protein | cytoplasm | yes |
| A1917870 | Encodes ETHYLENE-DEPENDENT GRAVITROPISM-DEFICIENT AND YELLOW-GREEN-LIKE 3 (EDY3), a SZP-like putative metalloprotease. Homolog of EDY1 found in cyanobacteria. | 4.49 | 4.09 | 2.14 | response to heat | metalloprotease activity | mitochondria | no |
| A19251910 | Member of Heat Stress Transcription Factor (Hsf) family, HSPA7A | 6.21 | 5.31 | 3.29 | response to heat | transcription factor | nucleus | no |
| A1968510 | AAR2 protein family | 1.24 | 1.73 | 1.15 | response to heat | unknown | chloroplast | no |
| A1913200 | GRAM domain family protein | 2.27 | 1.63 | 1.13 | response to heat | unknown | cytoplasm | no |
| A1964510 | TUNICAMYCIN INDUCED 1 (TNI1), a plant-specific ER stress-inducible protein. TNI1 mutation affects pollen surface morphology | 4.90 | 3.32 | 2.94 | response to heat | unknown | chloroplast | yes |
| A1917860 | Kunitz family trypsin and protease inhibitor protein | 2.35 | 1.81 | 1.33 | response to nitrate; nitrate transport | protease inhibitor | extracellular | no |
| A1965560 | myb-like transcription factor family protein | 1.89 | 1.14 | 1.07 | response to nitrate; nitrate transport | transcription factor | nucleus | no |
| A1967360 | Encodes a serine/threonine rich-like protein, SRM45. Involved in the regulation of stress-responsive alternative splicing. | 2.65 | 3.44 | 2.34 | RNA binding | alternative splicing | unknown | no |
| A1918510 | Embryo defective 2444 (em2444); FUNCTIONS IN: RNA binding, nucleoside binding, nucleic acid binding | 1.46 | 1.29 | 1.09 | RNA binding | unknown | nucleus | no |
| A1966860 | Encodes a member of GMYF subfamily class (GMYF2) whose activity is activated by auxin and auxin-like compounds. Enzyme involved in the ABA signaling during seed germination, dormancy and seedling growth. | 2.01 | 1.25 | 0.97 | seedling growth | kinase activity | cytoplasm | no |
| A1914720 | Member of MAP Kinase (MPK 9). | 1.49 | 1.15 | 0.97 | signal transduction | MAP kinase activity | nucleus | no |
| A1917340 | Alpha/beta-Hydrolases superfamily protein | 1.67 | 1.35 | 0.82 | unknown | hydrolyase activity | cytoplasm | no |
| A1917130 | Plant invertase/galactin methyltransferase inhibitor superfamily protein | 1.89 | 1.49 | 1.21 | unknown | hydrolyase activity | extracellular | no |
| A1916260 | Wall-associated kinase family protein; FUNCTIONS IN: kinase activity, INVOLVED IN: protein amino acid phosphorylation | 0.85 | 0.93 | 1.74 | unknown | kinase activity | extracellular | no |
| A1965630 | Concanavalin A-like lectin protein kinase family protein | 1.65 | 2.20 | 1.36 | unknown | kinase activity | plasma membrane | no |
| A1968170 | Encodes a protein 'NUCLEAR FACTOR Y, SUBUNIT C2' (NF-YC2) with similarity to a subunit of the CCAAT promoter motif binding complex of yeast. One of two members of this class (NF-YB) and expressed in vegetative and reproductive tissues | 2.36 | 2.38 | 1.40 | unknown | transcription factor activity | nucleus | no |
| A1968670 | Myb-like transcription factor family protein | 2.12 | 1.42 | 1.41 | unknown | transcription factor activity | nucleus | no |
| A1967590 | A20/AN1-like zinc finger family protein | 1.84 | 1.98 | 1.21 | unknown | transcription factor activity | nucleus | no |
| A1966800 | ABS (activator-lagged BR1 suppressor 1)-interacting factor 1 (AIF1) | 0.90 | 1.25 | 1.67 | unknown | transcription factor activity | nucleus | no |
| A1968575 | AB1 (live binding protein 3) (AIF3) | 2.48 | 1.75 | 1.25 | unknown | transcription factor activity | nucleus | yes |

| AHg540790 | Unknown protein | 1.43 | 1.07 | 0.67 | unknown | unknown | nucleus | no |
| AHg541740 | Dipease resistance protein (DRES, DRR, drr) family; FUNCTIONS IN: transmembrane receptor activity, nucleoside-diphosphate activity, nucleoside triphosphate activity, ATP binding | 2.04 | 1.02 | 1.16 | unknown | unknown | nucleus | no |
| AHg541750 | Dipease resistance protein (DRES, DRR, drr) family; FUNCTIONS IN: transmembrane receptor activity, nucleoside-diphosphate activity, nucleoside triphosphate activity, ATP binding | 1.65 | 0.96 | 1.06 | unknown | unknown | nucleus | no |
| AHg52420 | Unknown protein | 1.21 | 1.08 | 1.91 | unknown | unknown | cytoplasmic vesicle | no |
| AHg53048 | Potential natural antisense gene, locus overlaps with AT5053650 | 1.76 | 1.37 | 1.17 | unknown | unknown | unknown | no |
| AHg54670 | SPFH8 and 7PH8 domain-containing membrane-associated protein family | 1.61 | 1.02 | 1.30 | unknown | unknown | plasma membrane | no |

Table S4. Accession specific genes responsive to irradiance increase; genes more than 1.4-fold down-regulated at 1 hour after light onset when comparing plants exposed to increased irradiance to control plants. Irradiance in one, two or three accessions of Col-0, Ga-0 and Ts-1 and differentially (P=0.05) down-regulated between two or three accessions when comparing Col-0, Ga-0 and Ts-1.

Unlogged fold changes are shown, grey shaded values are <1.4 fold down-regulated, green shading indicates accession-specific difference in expression present in control conditions independent of irradiance increase. Acc. spec. in cont. = Accession-specific difference in expression present in control conditions, independent of irradiance increase

| Gene ID | Gene name and description | C-1 | G-1 | T-1 | GO Biological Process | GO Molecular Function | GO Cellular Component | Acc. spec. in cont. |
|-----------|---|------|------|------|----------------------------------|-------------------------------|-----------------------|---------------------|
| At1g71030 | Encodes a putative myb family transcription factor, MYBL2. In contrast to most other myb-like proteins its myb domain consists of a single repeat. A proline-rich region potentially involved in transactivation is found in the C-terminal part of the protein. Its transcript accumulates mainly in leaves. | 0.62 | 0.31 | 0.36 | alcoholamin biosynthesis | transcription factor activity | nucleus | yes |
| At4g00150 | Belongs to one of the LOM (LOST MERISTEMS) genes: AT2G45160 (LOM1), AT3G06030 (LOM2) and AT4G00150 (LOM3). LOM1 and LOM2 promote cell differentiation at the periphery of shoot meristems and help to maintain their polar organization. Member of Alpha-Expansin Gene Family. Involved in the formation of nematode-induced syncytia in roots of Arabidopsis thaliana. | 0.49 | 0.62 | 0.78 | cell organization and biogenesis | transcription factor activity | nucleus | no |
| AU2g00510 | Member of Alpha-Expansin Gene Family. Involved in the formation of nematode-induced syncytia in roots of Arabidopsis thaliana. | 0.48 | 0.53 | 0.85 | cell organization and biogenesis | unknown | extracellular | no |
| At2g18810 | Encodes Oxidation-related Zinc Finger 1 (OZF1), a plasma membrane protein involved in oxidative stress. | 1.16 | 0.77 | 0.81 | chlorophyll catabolic process | transcription factor activity | nucleus | no |
| At3g26740 | Transcripts are differentially regulated at the level of mRNA stability at different times of day controlled by the circadian clock. mRNAs are targets of the RNA degradation pathway mediated by the circadian clock (DCL1) instability dependent. | 0.82 | 0.54 | 0.44 | circadian rhythm | unknown | chloroplast | yes |
| At5g28740 | Encodes a choroplaid ferriic chelate reductase, FRO7. Shows differential splicing and has three different mRNA products. Expressed in the root, flower and cotyledon. | 0.52 | 0.89 | 0.49 | electron transport | ferriic chelate reductase | chloroplast | yes |
| At3g26470 | Member of C/P89A. | 0.70 | 0.86 | 1.40 | oxidation-reduction process | unknown | unknown | yes |
| At4g26470 | Encodes a member of the DREB subfamily A-1 of ERF/AP2 transcription factor family (GFP2). The protein contains one AP2 domain and is involved in responses to cold, drought, salinity, abscisic acid, and circadian rhythm. | 1.36 | 0.66 | 0.82 | phytoalexin biosynthesis | transcription factor activity | nucleus | no |
| At5g21590 | encodes a member of the ERF (ethylene response factor) subfamily B-3 of ERF/AP2 transcription factor family. The protein contains one AP2 domain. There are 16 members in this subfamily including ATERF-1, ATERF-2, AND ATERF-3. | 0.93 | 0.64 | 0.65 | phytoalexin biosynthesis | transcription factor activity | nucleus | no |
| At4g15660 | Thioredoxin superfamily protein. It is involved in iron homeostasis in this subfamily including ATFER-1, ATFER-2, AND ATFER-3. Disulfide isomerase activity. NVOU5D RN. Not from Arabidopsis. | 0.68 | 1.22 | 1.37 | redox homeostasis | isomerase | cytoplasm | yes |
| At2g18050 | Encodes HISTONE H1-3 (HIS-13); a structurally divergent linker histone whose gene expression is induced by dehydration and ABA. | 1.17 | 0.72 | 0.49 | response to drought | transcription factor activity | nucleus | yes |
| At5g14120 | Major scaffold superfamily protein | 0.68 | 0.89 | 1.24 | response to nitrate | unknown | vacuole | no |
| At4g03110 | Encodes a putative RNA-binding protein that is located in the cytoplasm and is involved in the hypersensitive response and Arabidopsis thaliana tobacco etch virus immunity. | 0.68 | 1.00 | 1.01 | RNA binding | RNA binding | cytoplasm | no |
| At3g26160 | RNA-binding (RRM/RDRMP motifs) family protein | 0.64 | 0.70 | 0.98 | RNA binding | transcription factor activity | nucleus | yes |
| At5g26310 | Encodes a class I HDZc (homeodomain-leucine zipper) protein that is a positive regulator of ABA-responsiveness, mediating the inhibitory effect of ABA on growth during seedling establishment. | 0.75 | 0.64 | 0.51 | seedling growth | transcription factor activity | nucleus | no |
| At1g52290 | Encodes a member of the proline-rich extensin-like receptor kinase (PREK) family. This family consists of 15 predicted receptor kinases (PRLK1-15653/587). | 0.69 | 0.83 | 1.03 | unknown | kinase activity | plasma membrane | no |
| AU2g00970 | MYB C1 | 1.14 | 0.67 | 0.73 | unknown | transcription factor activity | nucleus | no |
| At3g26970 | Encodes a member of the basic helix-loop-helix transcription factor family protein. | 0.99 | 0.69 | 0.40 | unknown | transcription factor activity | nucleus | yes |
| At5g15310 | Member of the R2R3 factor gene family, MYB16. | 0.68 | 0.93 | 1.09 | unknown | transcription factor activity | nucleus | no |

| Gene ID | Gene name and description | C-1 | G-1 | T-1 | GO Biological Process | GO Molecular Function | GO Cellular Component | Acc. spec. in cont. |
|-----------|---|------|------|------|-----------------------|-------------------------------|-----------------------|---------------------|
| At5g53200 | TRPTYCHON (TRY) | 0.60 | 0.82 | 1.06 | unknown | transcription factor activity | nucleus | no |
| At1g22160 | Unknown protein. | 1.44 | 0.81 | 0.86 | unknown | unknown | mitochondria | no |
| At1g72430 | SAUR-like auxin-responsive protein family | 0.58 | 0.93 | 1.13 | unknown | unknown | nucleus | yes |
| At3g17230 | EXORDIUM like 5 (EXL5) | 0.64 | 0.88 | 0.86 | unknown | unknown | extra cellular | no |
| At3g06145 | Unknown protein | 0.54 | 0.57 | 0.87 | unknown | unknown | mitochondria | yes |
| At3g48970 | Member of EXPANSIN-LIKE. | 0.59 | 0.84 | 1.11 | unknown | unknown | extra cellular | no |
| At4g17245 | RING-U-box superfamily protein | 0.54 | 0.85 | 0.83 | unknown | unknown | unknown | no |
| At5g10150 | Unknown protein | 0.48 | 0.58 | 0.74 | unknown | unknown | nucleus | no |
| At5g18020 | SAUR-like auxin-responsive protein family | 0.47 | 0.73 | 0.88 | unknown | unknown | mitochondria | yes |
| At5g28319 | Unknown protein | 0.67 | 1.04 | 1.12 | unknown | unknown | mitochondria | yes |
| At5g49800 | Unknown protein | 1.39 | 1.02 | 0.88 | unknown | unknown | unknown | yes |

Table S5. Time specific genes responsive to irradiance increase; genes more than 2.0-fold up-regulated in Col-0 when comparing plants exposed to increased irradiance to control plants, at 1, 3.5 or 25 hours after the irradiance increase and differentially (P=0.05) up-regulated between two or three time-points when comparing 1, 3.5, and 25 hours. Unlogged fold changes are shown, grey shaded values are >2.0 fold up-regulated, green shading indicates accession-specific difference in expression present in control conditions independent of irradiance increase. Time spec. in cont. = 1 Time-specific difference in expression present in control conditions, independent of irradiance increase

| Gene ID | Gene name and description | C-1 | C-3.5 | C-25 | GO Biological Process | GO Molecular Function | GO Cellular Component | Time spec. in cont. |
|-----------|---|------|-------|------|----------------------------------|----------------------------------|-----------------------|---------------------|
| A13514440 | Encodes 9-cis-epoxycarotenoid dioxygenase, a key enzyme in the biosynthesis of abscisic acid. Regulated in response to drought and salinity. Expressed in roots, flowers and seeds. Localized to the chloroplast stroma and thylakoid membrane. | 2.56 | 1.19 | 2.10 | abscisic acid biosynthesis | oxidation-reduction process | chloroplast | no |
| A13263090 | Encodes a protein with ABA 8'-hydroxylase activity, involved in ABA catabolism. Member of the CYP707A gene family. | 1.05 | 2.10 | 1.17 | abscisic acid catabolism | oxidoreductase activity | chloroplast | no |
| A14593950 | Belongs to cytochrome P450 and is involved in typtophan metabolism. Converts Trp to indole-3-acetylaldehyde (IAA), a precursor to IAA, and indole gluconolactams. | 1.03 | 2.20 | 1.15 | amino acid metabolism | cell organization and biogenesis | chloroplast | no |
| A11918130 | alpha-amylase, putative / 1,4-alpha-D-glucan glucoamylase | 0.91 | 2.03 | 0.95 | carbohydrate metabolism | enzyme, alpha amylase | extra cellular region | yes |
| A11948100 | Pectin lyase-like superfamily protein | 1.62 | 2.22 | 1.84 | carbohydrate metabolism | enzyme, pectin lyase | extra cellular region | yes |
| A13262007 | SWEET4, a nodulin MN3 family protein | 0.86 | 2.13 | 0.86 | carbohydrate metabolism | nodulin family protein | plasma membrane | no |
| A14592020 | Encodes an isomylase-like protein. Mutant studies show that the gene is strongly involved in starch breakdown. A GUS-reporter product was shown to localize to the surface of chloroplastic structures reminiscent of starch granules. In the Arabidopsis mutant, starch granules were reduced in size and number. | 1.20 | 2.10 | 1.86 | carbohydrate metabolism | starch degradation | chloroplast | yes |
| A14515210 | Cytosolic beta-amylase expressed in rosette leaves and inducible by sugar. RANT mutants have reduced beta amylase in leaves and stems. | 1.62 | 7.15 | 5.40 | carbohydrate metabolism | starch degradation | chloroplast | yes |
| A14517090 | Encodes a beta-amylase targeted to the chloroplast. Transgenic BMV8 RNAi lines fail to accumulate maltose during cold shock suggesting that maltose accumulation coincides with BMV8 expression. Apart from maltose, the sugar content of the RNAi lines were similar to wildtype (glucose and sucrose unaffected). | 0.93 | 2.19 | 0.94 | carbohydrate metabolism | starch degradation | chloroplast | yes |
| A15513170 | Encodes a member of the SWEET1 sucrose efflux transporter family proteins. | 1.48 | 2.57 | 3.61 | sucrobioside metabolism | transporter | plasma membrane | no |
| A11951600 | glucose-6-Phosphate/phosphate transporter 2 (GPT2) | 4.13 | 12.55 | 6.76 | sucrobioside metabolism | transporter | plasma membrane | no |
| A11957590 | Pectinacetyltransferase family protein | 1.19 | 2.44 | 1.28 | cell organization | hexosaccharide phosphorylation | chloroplast | yes |
| A14523990 | encodes a protein similar to cellulase synthase | 1.27 | 2.16 | 1.47 | cell organization and biogenesis | cell organization and biogenesis | extra cellular region | yes |
| A14525150 | Encodes a member of the G371, beta3 family of rice finger transcription factors. Modulate chlorophyll biosynthesis and glutamate synthase (GLUT1F-GOGAT) expression. | 0.77 | 2.72 | 0.46 | chlorophyll biosynthesis | cell organization and biogenesis | plasma membrane | yes |
| A11956090 | Disease resistance protein (TR-NBS class) | 2.37 | 0.94 | 1.77 | defense response | defense factor activity | nucleus | yes |
| A14503990 | Encodes an atypical dual-specific phosphatase involved in the negative regulation of defense response to a bacterial pathogen, P. syringae pv. tomato. | 2.27 | 1.17 | 1.46 | defense response | hydrolase activity | cytoplasm | no |
| A14526870 | Encodes one of the two subunits in the genome. Gene expression is enhanced by methyl jasmonate treatment. It is involved in the defense response to B. cinera. | 1.02 | 2.27 | 1.37 | defense response | hydrolase activity | chloroplast | no |
| A15511740 | Disease resistance protein (TR-NBS-LRR class) family | 2.04 | 0.91 | 1.32 | defense response | signal transduction | nucleus | yes |

| Gene ID | Gene name and description | C-1 | C-3,5 | C-25 | GO Biological Process | GO Molecular Function | GO Cellular Component | Time spec. in cont. |
|----------|--|------|-------|------|---------------------------------------|----------------------------------|-----------------------|---------------------|
| A1528470 | Member of the plant WRKY transcription factor family. Regulates the antagonistic relationship between defense pathways for necrotrophic and biotrophic fungal pathogens. Located in nucleus. Involved in response to various abiotic stresses, especially salt stress. | 2.47 | 0.78 | 1.81 | defense response | transcription factor activity | nucleus | yes |
| A1528350 | Regulator of chromosome condensation (RCC1) family protein | 2.07 | 1.10 | 1.64 | DNA modification | chromatin binding | unknown | no |
| A1527410 | Encodes a NAC transcription factor induced in response to desiccation. It is localized to the nucleus and acts as a transcriptional activator in abscisic acid-mediated dehydration response. | 2.15 | 0.91 | 2.20 | drought response | transcription factor activity | nucleus | no |
| A1510040 | Encodes glycinecine c. Promoter directs preferential expression in vascular tissues of cotyledons, leaves, roots, and hypocotyls, and in stems. | 1.42 | 2.05 | 1.35 | electron transport | electron carrier activity | mitochondria | no |
| A1525450 | Cytochrome bd ubiquinol oxidase, 14kDa subunit | 3.63 | 1.43 | 2.40 | electron transport | mitochondrial electron transport | mitochondria | no |
| A1158600 | GS22, a galactinol synthase that catalyzes the formation of galactinol from UDP-galactose and myo-inositol. GS22 transcript is induced in response to oxidative damage-inducing agent. Plants over-expressing GS22 have increased tolerance to salt, chilling, and high-light stress. | 2.49 | 1.23 | 1.36 | formation of galactinol | transferase activity | nucleus | yes |
| A1158600 | encodes a flavonoid-7-O-rhamnosyltransferase involved in the formation of rhamnosylated flavonoids | 1.36 | 2.03 | 1.58 | formation of rhamnosylated flavonoids | transferase activity | nucleus | no |
| A1518910 | Encodes a peroxisomal protein with acyl-CoA synthetase activity that is responsible for the activation of acetate for entry into the glyoxylate cycle. | 1.13 | 2.25 | 1.09 | formation of glyoxylate cycle | nucleotide binding | peroxisome | yes |
| A1525770 | Encodes allelic oxidase. One of four genes in Arabidopsis that encode this enzyme, which catalyzes an essential step in jasmonic acid biosynthesis. | 1.12 | 1.16 | 2.38 | jasmonic acid biosynthesis | unknown | chloroplast | yes |
| A1211740 | Member of the NAC transcription factor family and more specifically, the ONAC922 subfamily. Involved in leaf and inflorescence stem morphogenesis. | 2.29 | 0.75 | 1.98 | leaf morphogenesis | transcription factor activity | nucleus | yes |
| A1152300 | Encodes GRANULE BOUND STARCH SYNTHASE 1 (GBSS1); a UDP-Glycocytransferase superfamily protein | 0.97 | 2.44 | 0.92 | starch biosynthesis | glycosyl transferase | chloroplast | yes |
| A1158450 | RXWR, FUNCTIONS IN hydrolase activity, acting on ester bonds, lipase activity | 1.23 | 2.42 | 1.13 | lipid remodeling | hydrolase activity | chloroplast | yes |
| A1237870 | Bifunctional inhibitor/lipid-transfer protein/seed storage 2S albumin superfamily protein | 1.25 | 2.22 | 1.16 | lipid remodeling | lipid binding | extracellular region | no |
| A1242540 | Encodes COLD-REGULATED 15A (COR15A); a cold-regulated gene whose product is targeted to the chloroplast. Cor15a protects stromal proteins from aggregation under various stress conditions. | 1.88 | 2.36 | 1.27 | lipid remodeling | lipid binding | chloroplast | yes |
| A1526930 | LIPID TRANSFER PROTEIN 3 (LTP3); predicted to encode a PR (pathogenesis-related) protein. Belongs to the lipid transfer protein (PR-14) family. | 2.11 | 4.65 | 1.85 | lipid remodeling | lipid binding | extracellular region | yes |
| A1526940 | Encodes MONOGALACTOSYLGLYCEROL SYNTHASE 2 (MG2); a Type B monogalactosylglycerol (MGDG) synthase. Strongly induced by phosphate deprivation, and in non-photosynthetic tissues. Does not contribute to galactolipid synthesis under P-sufficient conditions but does under P starvation. | 2.22 | 0.83 | 1.08 | lipid remodeling | MGDG synthesis | chloroplast | no |
| A1549300 | Encodes SULFOQUINOVOSIDIACGLYCEROL 1 (SQD1); involved in sulfolipid biosynthesis | 2.31 | 1.45 | 1.65 | lipid remodeling | SQDG synthesis | chloroplast | no |
| A1521220 | Encodes SULFOQUINOVOSIDIACGLYCEROL 2 (SQD2); a UDP-sulfolipase DAG sulfolipid transferase that is involved in sulfolipid biosynthesis and whose expression is responsive to both phosphate (P) and phosphate (Pi) in both roots and shoots. | 2.32 | 0.80 | 1.12 | lipid remodeling | SQDG synthesis | chloroplast | no |
| A1520240 | Encodes SENESCENCE-RELATED GENE 3 (SRG3); a member of the glycerophospholipid transferase (GDP) family. | 6.54 | 0.97 | 1.85 | lipid remodeling | transcription factor activity | chloroplast | yes |
| A1520150 | Encodes SPX DOMAIN GENE 1 (SPX1). Expression is upregulated in the shoot of a xyl1 oak3 mutant. Additionally, its expression is responsive to both phosphate (Pi) and phosphate (Pi) in both roots and shoots. | 4.30 | 0.99 | 1.07 | lipid remodeling | unknown | nucleus | yes |
| A1171870 | Encodes ETHYLENE-DEPENDENT GRAVITROPISM-DEFICIENT AND YELLOW-GREEN-LINE 3 (EODY3), a SZP-like putative metalloprotease. | 4.49 | 1.31 | 1.81 | metal ion binding | metalloprotease | chloroplast | no |
| A1524930 | Metal-dependent protein hydrolase | 1.08 | 2.39 | 1.61 | metal ion binding | protein hydrolase | mitochondria | no |
| A1527450 | HEAVY METAL ASSOCIATED ISOPRENILATED PLANT PROTEIN 21 (HIPP21); heavy metal transport/ detoxification superfamily protein | 1.07 | 2.35 | 1.26 | metal ion binding | transporter | nucleus | no |

| Gene ID | Gene name and description | C-1 | C-3.5 | C-25 | GO Biological Process | GO Molecular Function | GO Cellular Component | Time spec. in cont. |
|-----------|---|------|-------|------|-------------------------|--------------------------------|-------------------------------|---------------------|
| At5g22750 | Heavy metal transport/uptake sugarfamily protein | 1.86 | 0.87 | 2.01 | metal ion binding | transporter | nucleus | no |
| At5g03780 | Encodes a cytosolic methionine synthase, involved in methionine regeneration via the activated methyl cycle (or SAM cycle) | 1.44 | 2.01 | 1.57 | methionine regeneration | transferase activity | chloroplast | yes |
| At5g17609 | Encodes a homolog of HY2 (HYH), involved in phyB signaling pathway. | 1.24 | 2.16 | 0.92 | photoreceptor response | HY2 homologue | nucleus | yes |
| At5g22840 | Encodes EARLY LIGHT-INDUCIBLE PROTEIN (ELIP1) | 2.97 | 9.66 | 5.03 | photosynthesis | chlorophyll binding | chloroplast | yes |
| At4g14690 | Encodes EARLY LIGHT-INDUCIBLE PROTEIN 2 (ELIP2) | 2.95 | 5.11 | 5.54 | photosynthesis | chlorophyll binding | chloroplast | yes |
| At1g98200 | Encodes a thioesterase-like protein (AT1G98200/ELN1, AT1G98200/FLN2), mutants display mutant chloroplast development, general plant growth and development defects and defects in PEP-dependent transcription. | 0.92 | 1.42 | 2.27 | photosynthesis | thioesterase | chloroplast | no |
| At5g44090 | Encodes a thioesterase-like protein (AT5G44090/ELN1, AT5G44090/FLN2), a member of the pfl6-cathoxylase kinase family, involved in chloroplast development, general plant growth and development defects and defects in PEP-dependent transcription. | 0.90 | 1.31 | 2.45 | photosynthesis | thioesterase | chloroplast | no |
| At3g28900 | Encodes ACEF16, a 16-kDa plastid outer membrane protein involved in plastid import of protobiopteridine oxidoreductase | 1.01 | 2.19 | 1.18 | photosynthesis | chloroplast protein import | chloroplast | no |
| At3g13470 | Encodes a subunit of chloroplast chaperonins that are involved in mediating the folding of newly synthesized, translocated, or stress-denatured proteins. | 2.02 | 1.60 | 2.42 | photosynthesis | chloroplast protein import | chloroplast | no |
| At5g04530 | Encodes a protein with RNase Z activity suggesting a role in rRNA processing. Protein contains a signal sequence for import into the chloroplast. | 0.91 | 1.58 | 2.23 | photosynthesis | chloroplast transcrip/govern | chloroplast | no |
| At5g23910 | NAD(P)-binding Rossmann-fold superfamily protein | 1.20 | 1.03 | 2.77 | photosynthesis | salicylic acid biosynthesis | unknown | no |
| At5g29590 | At5g29590 (ASMAT1) encodes a methyl-CoA synthetase, or O-methyltransferase that is constitutively expressed with a epistatic 5-O-anticyanidin glucosyltransferase (At4g14690). The enzyme is involved in the malonylation of anthocyanins in Arabidopsis. | 1.17 | 1.28 | 2.66 | photosynthesis | flavonoid biosynthesis | cytoplasm | no |
| At4g14690 | The At4g14690 encodes an anthocyanidin 5-O-glucosyltransferase specifically glucosylating the 5-position of the flavonoid A-ring. | 1.07 | 1.13 | 2.09 | photosynthesis | flavonoid biosynthesis | chloroplast | no |
| At4g22880 | Encodes leucocyanidin 4-hydroxylase, which is involved in proanthocyanin biosynthesis. Mutant analysis suggests that this gene is also involved in vacuole formation. | 1.97 | 1.35 | 7.59 | photosynthesis | flavonoid biosynthesis | cytoplasm | yes |
| At5g07990 | Required for flavonoid 2' hydroxylase activity. Enzyme abundance relative to CHS determines Quercetin/Kaempferol metabolic ratio. | 1.21 | 1.72 | 4.03 | photosynthesis | flavonoid biosynthesis | extra-cellular region | no |
| At5g08640 | Encodes FLAVONOL SYNTHASE 1 (FLS1) that catalyses formation of flavonoid from dihydroflavonol. Co-expressed with CH and CHS (RT-PCR). | 1.40 | 2.16 | 2.22 | photosynthesis | flavonoid biosynthesis | cytoplasm | no |
| At5g13300 | Encodes chalcone synthase (CHS), a key enzyme involved in the biosynthesis of flavonoids. Required for the accumulation of purple anthocyanins in leaves and stems. Also involved in the regulation of auxin transport and the modulation of root gravitropism. | 1.29 | 1.99 | 2.04 | photosynthesis | flavonoid biosynthesis | cytoplasm | yes |
| At5g17220 | Encodes GLUTATHIONE S-TRANSFERASE PH12 (GSTF12) belonging to the phi class of GSTs. Likely to function as a carrier to transport anthocyanin from the cytosol to vacuoplasts. | 1.91 | 1.29 | 6.66 | photosynthesis | flavonoid biosynthesis | cytoplasm | yes |
| At5g24800 | At5g24800 encodes a flavonoid 3-O-glucosyltransferase. Catalyzes the conversion of dihydroquercetin to leucocyanidin in the biosynthesis of anthocyanins. Not expressed in roots (RT-PCR). | 1.56 | 1.39 | 6.68 | photosynthesis | flavonoid biosynthesis | endoplasmic reticulum | yes |
| At5g04880 | Encodes a penicillin 3-oxo-acyl-CoA thioesterase 2 precursor. EC2.3.1.18 thioesterase. AT5G04880.1 is named PRT1 and AT5G04880.2 is named PRT2. | 1.16 | 1.48 | 2.20 | photosynthesis | flavonoid biosynthesis | peroxisome | yes |
| At5g22210 | Enzyme-specific protein 3, (AT53) | 1.80 | 1.89 | 4.23 | photosynthesis | flavonoid biosynthesis | acrosed component of membrane | no |
| At3g51240 | Encodes flavanone 3-hydroxylase that is constitutively expressed with chalcone synthase and chalcone isomerase. Regulates flavonoid biosynthesis. Not responsive to auxin or ethylene stimulus (RT-PCR). | 1.64 | 2.43 | 1.75 | photosynthesis | flavonoid biosynthesis | cytoplasm | yes |
| At5g44090 | Encodes an anthocyanin 3-O-glucosyl-2'-O-acetyltransferase involved in anthocyanin modification that converts cyanidin 3-O-glucoside to cyanidin 3-O-xyloxy(1-2)-glucoside. Its preferred sugar donor is UDP-xylose. | 1.20 | 1.26 | 2.70 | photosynthesis | glycosyl flavonoid transferase | chloroplast | no |

| Gene ID | Gene name and description | C-1 | C-3,5 | C-25 | GO Biological Process | GO Molecular Function | GO Cellular Component | Time spec. in cont. |
|-----------|---|------|-------|------|----------------------------------|--|-----------------------|---------------------|
| A1503770 | Encodes an NADPH-dependent aldo-keto reductase that can act on a wide variety of substrates in vitro including saturated aldehydes and ketones. The protein is located in the chloroplast where it may play a role in detoxifying reactive carbonyl compounds that threaten to impair the photosynthetic process. | 1.19 | 2.37 | 1.71 | photosynthesis | H2O2 scavenging | chloroplast | no |
| A1503850 | Encodes a protein that possesses S-allylthiosulfinate synthase activity and lacks O-acetylserine(thiol)lyase activity. | 0.87 | 1.02 | 2.10 | photosynthesis | H2O2 scavenging | chloroplast | no |
| A14931870 | Encodes GLUTATHIONE PEROXIDASE 7 (GPX7) | 1.96 | 3.65 | 2.51 | photosynthesis | H2O2 scavenging | chloroplast | yes |
| A15041780 | A15041780 encodes an enzyme involved in the early steps of NAD biosynthesis. In contrast to the EC 1.4.3.16 (i.e. NAD synthase) that catalyzes the reaction L-aspartate + O ₂ → iminoaspartate (beta-iminoaspartate) + H ₂ O ₂ . | 0.91 | 2.08 | 0.75 | photosynthesis | NAD metabolism | mitochondria | yes |
| A1504470 | VEGETATIVE STORAGE PROTEIN 2 (VSP2), has acid phosphatase activity, dependent on the presence of divalent cations (Mg ²⁺ and Mn ²⁺). The protein shows a related development, induced in response to abscisic acid, jasmonic acid, salt, water deficiency and wounding. | 1.15 | 3.65 | 1.99 | photosynthesis | nutrient mobilization | chloroplast | no |
| A15044780 | VEGETATIVE STORAGE PROTEIN 1 (VSP1), an acid phosphatase similar to soybean vegetative storage proteins. Gene expression is induced by wounding and jasmonic acid. | 1.26 | 7.95 | 3.06 | photosynthesis | nutrient mobilization | chloroplast | no |
| A14904020 | Fibrin precursor protein. The fibrin protein, but not the mature protein interacts with ABI2. Regulated by abscisic acid response regulators. Involved in abscisic acid-mediated photoprotection. | 2.26 | 1.87 | 1.33 | photosynthesis | photoprotection | chloroplast | yes |
| A11927720 | Encodes SALT TOLERANCE ZINC FINGER 10 (ZAT10), acts as a transcriptional repressor and is responsive to chitin oligomers. Also involved in response to photooxidative stress. | 3.15 | 1.09 | 2.38 | photosynthesis | photoprotection, transcription factor | nucleus | yes |
| A1529820 | RESPONSIVE TO HIGH LIGHT 41 (RH41), encodes a zinc-finger protein involved in high light and cold acclimation. The protein is induced in response to high light and cold stresses and shows a constitutive increase in expression level of 15 cold-responsive genes, including CBF genes. Also, lines overexpressing this gene exhibits a small but reproducible increase in freeze tolerance. Because of the repression of the CBF genes by the overexpression of this gene, the authors speculate that this gene may be involved in negative regulatory circuit of the CBF pathway. | 2.48 | 0.99 | 1.55 | photosynthesis | transcription factor activity | nucleus | yes |
| A12974460 | *MYB12 belongs to subgroup 7 of the R2R3-MYB family. It strongly activates the promoters of chalcone synthase (CHS), flavone 3-hydroxylase (F3H), flavonoid 3-O-glucosyltransferase (F3GT) and dihydroflavonol 4-reductase (DFR), but cannot activate the promoters of isoflavone 3-hydroxylase (I3H) and dihydroflavonol 4-reductase (DFR). | 1.82 | 1.17 | 3.04 | photosynthesis | transcription factor activity, transcription factor activity, biosynthesis | nucleus | no |
| A11545570 | Encodes PHYLLOESTER SYNTHASE 1 (PES1), a protein with both ester synthase and diacylglycerol synthase activities that is involved in the deposition of free glycol and free fatty acids in the form of PHYLLOESTER in chloroplasts, a process involved in maintaining the integrity of the photosynthetic membrane during abiotic stress and senescence. | 1.12 | 2.34 | 1.44 | photosynthesis | transcription factor activity | chloroplast | no |
| A11928370 | encodes a member of the ERF (ethylene response factor) subfamily B-1 of ERF/AP2 transcription factor family. | 2.68 | 1.22 | 2.13 | photosynthesis; drought response | transcription factor activity | nucleus | yes |
| A11974820 | encodes a member of the DREB subfamily A-5 of ERF/AP2 transcription factor family. | 3.85 | 0.85 | 3.55 | photosynthesis; drought response | transcription factor activity | nucleus | no |
| A12903880 | Encodes ERF5A, a drought-induced transcription factor. Belongs to the AP2/ERF superfamily. | 2.84 | 1.62 | 1.93 | photosynthesis; drought response | transcription factor activity | nucleus | no |
| A14971500 | Encodes a member of the ERF (ethylene response factor) subfamily B-3 of ERF/AP2 transcription factor family (ATERF-1). The protein contains one AP2 domain. There are 18 members in this subfamily including ATERF-1, ATERF-2, AND ATERF-5. | 1.64 | 0.92 | 2.11 | photosynthesis; drought response | transcription factor activity | nucleus | no |
| A1506410 | Encodes DRE BINDING PROTEIN 2A (DREB2A), a transcription factor that specifically binds to DRE/CRT cis-elements (high and low-temperature stress), belongs to the DREB subfamily A-2 of ERF/AP2 transcription factor family (DREB2A) | 3.64 | 1.42 | 1.46 | photosynthesis; drought response | transcription factor activity | nucleus | yes |
| A15111590 | encodes a member of the DREB subfamily A-4 of ERF/AP2 transcription factor family. | 1.48 | 2.21 | 1.33 | photosynthesis; drought response | transcription factor activity | nucleus | no |

| Gene ID | Gene name and description | C-1 | C-3,5 | C-25 | GO Biological Process | GO Molecular Function | GO Cellular Component | Time spec. in cont. |
|-----------|--|-------|-------|------|-----------------------|----------------------------------|-----------------------|---------------------|
| A1562860 | Encodes a member of the Lon protease-like proteins (Lon1/AN562860, Lon2/AN57040, Lon3/AN595760, Lon4/AN595780). These proteins are involved in the degradation of abnormal, damaged and unstable proteins. Lon proteases are responsible for the degradation of abnormal, damaged and unstable proteins. | 1.10 | 2.40 | 1.55 | metabolism | cell organization and biogenesis | mitochondria | no |
| A1311020 | Unknown protein | 3.21 | 0.87 | 1.50 | respiration | anaerobic respiration | nucleus | no |
| A11563540 | HSP20-like chaperones superfamily protein | 8.12 | 3.32 | 3.45 | response to heat | chaperone | cytoplasm | no |
| A11564000 | HSP20-like chaperones superfamily protein | 3.23 | 1.56 | 1.88 | response to heat | chaperone | cytoplasm | yes |
| A11971000 | Chaperone DnaJ-domain superfamily protein | 3.91 | 1.16 | 1.23 | response to heat | chaperone | cytoplasm | no |
| A12946240 | A member of Arabidopsis BAG (BAG2-associated atrogenase) proteins, plant homologs of mammalian regulators of apoptosis. Expression of BAG3 in leaves was strongly induced by heat stress. | 7.26 | 1.50 | 3.05 | response to heat | chaperone | nucleus | no |
| A15948570 | Encodes one of the 36 carboxylesterase (CE) gene family members (CE1-CE36). These proteins are involved in the degradation of abnormal, damaged and unstable proteins. | 9.47 | 3.27 | 4.30 | response to heat | chaperone | cytoplasm | yes |
| A14928780 | Unknown protein | 1.48 | 1.76 | 2.00 | response to heat | chaperone | cytoplasm | no |
| A12621150 | Encodes HEAT SHOCK TRANSCRIPTION FACTOR 22 (HSFA22); member of Heat Stress Transcription Factor (HSF) family. Involved in response to imbalanced protein accumulation in the cytosol. | 3.69 | 1.63 | 1.81 | response to heat | heat shock factor | chloroplast | yes |
| A13251910 | HEAT SHOCK TRANSCRIPTION FACTOR 7A (HSFA7A); member of Heat Stress Transcription Factor (HSF) family | 6.21 | 1.10 | 2.18 | response to heat | heat shock factor | nucleus | yes |
| A14969890 | HEAT SHOCK FACTOR 2 (HSFA2); encodes a protein whose sequence is similar to heat shock factors that regulate the expression of heat shock genes. It is induced by heat shock. However, the expression of this gene did not result in the increase or decrease of heat shock proteins. | 2.60 | 1.66 | 1.74 | response to heat | heat shock factor | nucleus | yes |
| A11569860 | HSP20-like chaperones superfamily protein | 4.55 | 1.42 | 2.54 | response to heat | heat shock protein | cytoplasm | no |
| A11974310 | Encodes ClpB1, which belongs to the Clp family protease/heat shock protein 100 (Clp/Hsp100) family. | 5.50 | 2.14 | 2.55 | response to heat | heat shock protein | chloroplast | yes |
| A12019310 | HSP20-like chaperones superfamily protein | 2.02 | 1.63 | 1.45 | response to heat | heat shock protein | cytoplasm | no |
| A13201560 | DNA heat shock family protein | 4.46 | 1.66 | 2.40 | response to heat | heat shock protein | cytoplasm | yes |
| A12025140 | Encodes ClpB4, which belongs to the Clp family protease/heat shock protein 100 (Clp/Hsp100) family. | 3.13 | 1.58 | 2.12 | response to heat | heat shock protein | chloroplast | no |
| A12025500 | HSP20-like chaperones superfamily protein | 14.12 | 9.75 | 6.82 | response to heat | heat shock protein | cytoplasm | no |
| A12021220 | heat shock protein 701-2 (HSP701-2) | 2.60 | 1.36 | 2.00 | response to heat | heat shock protein | cytoplasm | no |
| A13068970 | J domain protein localized in ER lumen, shows similarity to HSP40 proteins and is induced by heat stress. | 4.69 | 1.58 | 2.51 | response to heat | heat shock protein | endoplasmic reticulum | no |
| A13069350 | Encodes one of the Arabidopsis orthologs of the human Hsp70-binding protein 1 (HspBP-1) | 4.70 | 1.31 | 1.50 | response to heat | heat shock protein | cytoplasm | yes |
| A13069320 | Encodes a high molecular weight member of the FK506 binding protein (FKBP) family. It has three FKBP12-like domains, a tripeptide repeats, and a putative calmodulin binding domain. Modulates thermotolerance by interacting with HSP90,1 and affecting the accumulation of HSP90-regulated sHSPs. | 2.58 | 1.25 | 1.58 | response to heat | heat shock protein | cytoplasm | no |
| A13068220 | HEAT SHOCK PROTEIN 17.4 (HSP17.4); member of the class I small heat shock protein (sHSP) family, which accounts for the majority of sHSPs in tubular areas. | 10.13 | 4.69 | 4.88 | response to heat | heat shock protein | cytoplasm | no |

| Gene ID | Gene name and description | C-1 | C-3,9 | C-25 | GO Biological Process | GO Molecular Function | GO Cellular Component | Time spec. in cont. |
|-----------|---|-------|-------|-------|-----------------------|------------------------|-----------------------|---------------------|
| A1g912400 | Encodes HSPs (Hsp3), one of the 36 carboxylate clamp (CO) hetero-coiled repeat (TPR) proteins (Praad 2010, Dubredet 2008, Dubredet 2008) with potential to interact with Hsp90/17 as co-chaperones. | 9.12 | 3.43 | 3.77 | response to heat | heat shock protein | nucleus | yes |
| A1g91320 | Encodes heat stress-associated 32-kD protein. Up-regulated by heat shock. Thermotolerance in a knockout mutant was compromised following a lag recovery period (> 24 h) after acclimation heat shock treatment. | 2.29 | 1.17 | 1.86 | response to heat | heat shock protein | nucleus | no |
| A1g92300 | AHSP23,emile mRNA, nuclear gene encoding mitochondrial | 5.64 | 2.83 | 3.04 | response to heat | heat shock protein | mitochondria | no |
| A1g92490 | Heat shock protein 70 (Hsp 70) family protein (Hsp702) | 2.10 | 1.23 | 1.62 | response to heat | heat shock protein | cytosol | no |
| A1g92990 | heat shock protein 70 (Hsc70-5); nuclear | 2.90 | 1.96 | 1.78 | response to heat | heat shock protein | mitochondria | no |
| A1g912000 | Encodes HEAT SHOCK PROTEIN 17.6A (HSP17.6A), a cytosolic small heat shock protein with chaperone activity that is induced by heat and osmotic stress and is also expressed late in seed development. | 20.49 | 5.26 | 12.83 | response to heat | heat shock protein | cytoplasm | no |
| A1g927670 | HSP20-like chaperones superfamily protein | 4.25 | 1.31 | 4.08 | response to heat | heat shock protein | cytoplasm | no |
| A1g921440 | HSP20-like chaperones superfamily protein | 7.07 | 4.39 | 4.07 | response to heat | heat shock protein | mitochondria | no |
| A1g92840 | Encodes a cytosolic heat shock protein AHSR90.1. AHSR90.1 interacts with disease resistance signaling components SOT1b and RAR1 and is required for RRS2-mediated resistance. | 7.76 | 2.68 | 3.41 | response to heat | heat shock protein | cytosol | yes |
| A1g93070 | SGS domain-containing protein | 3.56 | 1.46 | 2.31 | response to heat | unknown | nucleus | no |
| A1g96080 | Unknown protein | 2.72 | 1.38 | 1.36 | response to heat | unknown | cytoplasm | yes |
| A1g913200 | Encodes a protein with unknown function that is involved in hormone mediated regulation of seed germination/ dormancy. | 2.27 | 1.12 | 1.65 | response to heat | unknown | cytoplasm | no |
| A1g94510 | Encodes Tunicamycin induced 1 (TIN1), a plant-specific ER stress-inducible protein. TIN1 mutation affects pollen surface morphology. Transcriptionally induced by treatment with the N-glycosylation inhibitor tunicamycin. | 4.90 | 2.36 | 2.22 | response to heat | unknown | chloroplast | yes |
| A1g960200 | A member of heat shock protein 90 (HSP90) gene family. Expressed in all tissues and abundant in root apical meristem, pollen and sporium. Expression is induced by heat, abscisic acid (ABA), and NaCl. Interacts with HsfA1D in the cytosol and P1b helicase and the guanylyltransferase HsfA1d. DDB1 hot spot to ADP/ATP. | 2.05 | 1.32 | 1.18 | response to heat | chaperone | CoG1 apparatus | yes |
| A1g913490 | Encodes mitochondrial ADP/ATP carrier | 1.08 | 2.25 | 1.44 | response to nitrate | ammonium transporter | chloroplast | no |
| A1g94780 | encodes an ammonium transporter protein believed to act as a high affinity transporter. It is expressed in the root, primarily in endodermal and cortical cells, and contributes to ammonium uptake in the root. | 1.13 | 2.85 | 1.18 | response to nitrate | ammonium transporter 1 | plasma membrane | yes |
| A1g96870 | Encodes a low affinity nitrate transporter NRT1.7. Expressed in phloem. Responsible for source-to-sink remobilization of nitrate. | 1.28 | 2.57 | 1.63 | response to nitrate | nitrate transporter | plasma membrane | no |
| A1g97860 | Kunitz family trypsin and protease inhibitor protein | 2.35 | 0.98 | 1.23 | response to nitrate | protease inhibitor | cell wall | no |
| A1g97350 | Encodes a serine/arginine rich-like protein, SR45a. Involved in the regulation of stress-responsive alternative splicing. | 2.65 | 1.75 | 1.98 | RNA binding | alternative splicing | spliceosomal complex | yes |
| A1g99140 | Encodes a serine-arginine rich RNA binding protein SR30) involved in regulation of splicing (including splicing of heat). | 2.36 | 2.30 | 1.67 | RNA binding | alternative splicing | nucleus | no |
| A1g927280 | Gene encodes a methyltransferase-like protein involved in pre-mRNA processing. | 1.13 | 2.06 | 1.31 | RNA binding | methyl transferase | nucleus | no |
| A1g922310 | PUTATIVE MITOCHONDRIAL RNA HELICASE 1 (PMH1). Sequence similarity of DEAD-box RNA helicases. Binds RNA and DNA. Involved in drought, salt and cold stress responses. | 0.91 | 2.01 | 1.16 | RNA binding | organellar RNA editing | nucleus | no |
| A1g15440 | Encodes a nuclear protein that is a ribosome biogenesis co-factor. Mutants display aberrant RNA processing and female gametophyte development. | 1.04 | 2.04 | 1.21 | RNA binding | ribosome biogenesis | nucleus | no |

| Gene ID | Gene name and description | C-1 | C-3.5 | C-25 | GO Biological Process | GO Molecular Function | GO Cellular Component | Time spec. in cont. |
|-----------|---|------|-------|------|-----------------------|--|--------------------------------|---------------------|
| A1522100 | RNA cyclase family protein | 1.07 | 2.05 | 1.28 | RNA binding | ribosome biogenesis | nucleus | no |
| A1529890 | Ribosomal protein S4 | 1.23 | 2.00 | 1.36 | RNA binding | ribosome biogenesis | cytosol | no |
| A1646500 | encodes a fibrin, a key nucleolar protein in eukaryotes which associates with box C/D small nucleolar RNA (snRNAs) directing 2'-O-methylation of the RNA. | 1.02 | 2.02 | 1.56 | RNA binding | rRNA editing | nucleus | yes |
| A1568880 | encodes a member of SNF1-related protein kinases (SnRK2), whose activity is activated by ionic (salt) and non-ionic (osmotic) osmotic stress. Enzyme involved in the ABA signaling during seed germination, dormancy and seedling growth. | 2.01 | 0.89 | 1.32 | seedling growth | kinase activity | cytoplasm | yes |
| A13916000 | Encodes a protein with pyridoxal phosphate synthase activity whose transcripts were detected mostly in roots and accumulate during senescence. The protein was found in very low abundance, which prevented a specific localisation. | 2.89 | 1.65 | 1.57 | sensory perception | protein binding | cytoplasm | yes |
| A1191810 | Encodes JASMONATE-ZIM-DOMAIN PROTEIN 1 (JAZ1), a nuclear-localized protein involved in jasmonate signaling | 4.20 | 1.27 | 3.77 | signal transduction | protein binding | nucleus | yes |
| A1192520 | PLATLH2 domain-containing lipoygenase family protein | 2.33 | 1.19 | 2.20 | signal transduction | signal transduction | chloroplast | no |
| A1193070 | LIFEGUARD 4 (LEGA4), a box inhibitor-1 family protein | 4.02 | 1.05 | 1.33 | unknown | glutamate binding | integral component of membrane | no |
| A11943910 | P-loop containing nucleoside triphosphate hydrolases superfamily protein | 1.22 | 1.26 | 2.03 | unknown | hydrolase activity | Golgi apparatus | no |
| A12623010 | serine carboxypeptidase-like 9 (SCPL9) | 1.25 | 2.03 | 2.48 | unknown | hydrolase activity | extracellular region | yes |
| A1267420 | Cysteine proteinases superfamily protein | 1.40 | 3.05 | 0.98 | unknown | hydrolase activity | unknown | yes |
| A1363320 | ATPase, AAA-type, CDC48 protein | 3.05 | 1.81 | 2.57 | unknown | hydrolase activity | cytosol | no |
| A1417470 | alpha-beta-Hydrolases superfamily protein | 0.99 | 2.70 | 1.45 | unknown | hydrolase activity | chloroplast | no |
| A1528310 | Encodes a protein shown to have methyl IAA esterase activity in vitro. This protein does not act on methyl-IA, MeSA, MeGA4, or MeGA9 in vitro. | 1.01 | 1.45 | 2.18 | unknown | hydrolase activity | cytoplasm | no |
| A11918640 | Encodes a S-adenosyl-L-methionine:jasmonic acid carboxyl methyltransferase (JMT) that catalyzes the formation of methyljasmonate from jasmonic acid. | 0.92 | 2.39 | 1.17 | unknown | jasmonic acid methyltransferase activity | nucleus | no |
| A13011620 | P-loop containing nucleoside triphosphate hydrolases superfamily protein | 1.41 | 2.47 | 1.11 | unknown | kinase activity | mitochondria | no |
| A1310530 | TransducinWD40 repeat-like superfamily protein | 0.92 | 2.05 | 1.23 | unknown | nucleoside binding | nucleus | no |
| A1264660 | member of Cyclochroma b5 | 1.22 | 1.35 | 2.01 | unknown | oxidation-reduction process | integral component of membrane | yes |
| A13644970 | Cyclochrome P450 superfamily protein | 1.07 | 0.96 | 2.22 | unknown | oxidation-reduction process | unknown | no |
| A1260830 | encodes a protein whose sequence is similar to 2-oxoglutarate-dependent dioxygenase | 1.19 | 2.50 | 1.18 | unknown | oxidoreductase activity | cytoplasm | no |
| A14112290 | Copper amine oxidase family protein | 1.10 | 2.13 | 1.16 | unknown | oxidoreductase activity | Golgi apparatus | yes |
| A11905010 | OPC-810 CoA ligase1 (OPCL1); FUNCTIONS IN: 4-oxumarate-CoA ligase activity | 1.92 | 1.08 | 2.08 | unknown | phenylpropanoid metabolic process | peroxisome | yes |
| A12618220 | Encodes a protein that might have inorganic pyrophosphatase activity. | 1.06 | 2.10 | 1.40 | unknown | phosphate ion homeostasis | cytoplasm | no |
| A12638170 | Encodes a high affinity vacuolar calcium antiporter. | 1.15 | 2.10 | 1.10 | unknown | phosphate ion homeostasis | chloroplast | no |

| Gene ID | Gene name and description | C-1 | C-3,5 | C-25 | GO Biological Process | GO Molecular Function | GO Cellular Component | Time spec. in cont. |

| A1920210 | glutamate decarboxylase 4 (GAD4) | 1.19 | 2.49 | 1.28 | unknown | protein binding | nucleus | no |
| A19203060 | ED3, is an F-box protein involved that mediates the regulation of abscisic acid signalling. | 1.59 | 2.11 | 1.48 | unknown | protein binding | nucleus | no |
| A19173325 | Kunitz family 1 type 1 and protease inhibitor protein | 1.39 | 5.63 | 4.26 | unknown | protein metabolism | extracellular region | yes |
| A19189020 | Unknown protein | 1.99 | 0.78 | 2.17 | unknown | response to oxidative stress | unknown | no |
| A19101185 | Encodes a Gibberellin-regulated GASAGAST/Shakin family protein | 1.21 | 3.67 | 2.21 | unknown | signal transduction | extracellular region | no |
| A1914720 | member of MAP Kinase | 1.49 | 2.16 | 1.51 | unknown | signal transduction | nucleus | no |
| A19247710 | encodes a arginine decarboxylase (ADC), a rate-limiting enzyme that catalyzes the first step of polyamine (PA) biosynthesis via the PCDC pathway in Arabidopsis thaliana. | 1.25 | 2.80 | 1.26 | unknown | signal transduction | nucleus | no |
| A191671210 | DNA-directed RNA polymerase, subunit M, archaeal | 1.12 | 2.05 | 1.02 | unknown | transcription | nucleus | no |
| A19195180 | MYB13, member of MYB3R- and R2R3- type MYB- encoding genes | 1.50 | 2.38 | 0.99 | unknown | transcription factor activity | nucleus | yes |
| A19195170 | 'NUCLEARFACTOR Y, SUBUNIT C2' (NF-YC2) | 2.36 | 1.34 | 2.30 | unknown | transcription factor activity | nucleus | no |
| A191958870 | myx-like transcription factor family protein | 2.12 | 0.99 | 1.51 | unknown | transcription factor activity | nucleus | no |
| A191959490 | Pattergen-induced transcription factor. | 2.59 | 1.03 | 2.32 | unknown | transcription factor activity | nucleus | yes |
| A19211150 | Encodes a protein with a B-box domain predicted to act as a transcription factor. Expression of the BBX23 gene is affected by monoclonal antibody 10A11. | 1.17 | 2.42 | 0.77 | unknown | transcription factor activity | nucleus | yes |
| A19211890 | B-box type zinc finger family protein | 1.18 | 3.86 | 1.02 | unknown | transcription factor activity | nucleus | yes |
| A19241500 | One of three genes in A. thaliana encoding multiplexin-binding factor 1, a highly conserved transcriptional coactivator. May serve as a binding factor between a bZIP factor and TBP. | 2.35 | 1.94 | 1.72 | unknown | transcription factor activity | nucleus | yes |
| A19252610 | Member of the R2R3 factor gene family. | 1.37 | 1.50 | 2.11 | unknown | transcription factor activity | nucleus | no |
| A19254840 | bZIP protein; FUNCTIONS IN: DNA binding, sequence-specific DNA binding transcription factor activity | 2.44 | 1.52 | 1.56 | unknown | transcription factor activity | nucleus | no |
| A19249330 | Member of the R2R3 factor gene family. | 1.03 | 2.26 | 0.91 | unknown | transcription factor activity | nucleus | yes |
| A19252900 | Encodes GSTF6, a glutathione transferase belonging to the phi class of GSTs. | 1.16 | 1.16 | 3.04 | unknown | transferase activity | cytoplasm | no |
| A19153360 | Encodes glutathione transferase GSTU28; belonging to the tau class of GSTs. | 2.87 | 1.14 | 1.36 | unknown | transferase activity | cytoplasm | yes |
| A19216890 | UDP-Glycosyltransferase superfamily protein | 1.12 | 2.12 | 1.37 | unknown | transferase activity | cytoplasm | yes |
| A19203460 | acetyl CoA:(2S)-hexan-1-ol acyltransferase (CHAT) | 0.94 | 2.16 | 1.12 | unknown | transferase activity | chloroplast | yes |
| A19115490 | Encodes a protein that might have synaptic acid UDP-glucose glucosyltransferase activity. | 1.32 | 2.03 | 1.24 | unknown | transferase activity | cytoplasm | no |
| A19116590 | encodes a gene similar to cellulose synthase | 1.06 | 6.69 | 3.95 | unknown | transferase activity | unknown | no |
| A19247790 | Leucine carboxyl methyltransferase | 1.17 | 2.27 | 0.93 | unknown | transferase activity | Cofactor | yes |
| A19258770 | Undecaprenylphosphatide synthetase family protein | 1.54 | 2.17 | 1.04 | unknown | transferase activity | chloroplast | yes |

| A15628470 | Unknown protein | 0.89 | 1.57 | 2.43 | unknown | unknown | chloroplast | no |
| A15629480 | ACP1 encodes a novel C12-binding protein, which shares sequence similarities with calmodulins. The expression of ACP1 is induced by NaCl. | 1.19 | 2.42 | 0.85 | unknown | unknown | cytoplasm | yes |
| A15624165 | Unknown protein | 3.62 | 1.39 | 2.72 | unknown | unknown | chloroplast | no |
| A15621820 | Unknown protein | 1.43 | 2.06 | 1.24 | unknown | unknown | chloroplast | no |
| A15623067 | Encodes a Plant thionin family protein | 1.39 | 2.26 | 1.96 | unknown | unknown | extracellular region | yes |
| A15624401 | Unknown protein | 4.63 | 1.63 | 1.28 | unknown | unknown | mitochondria | yes |
| A156200170 | Unknown protein | 1.44 | 2.17 | 2.64 | unknown | unknown | mitochondria | no |
| A156200620 | Unknown protein | 1.44 | 2.17 | 2.64 | unknown | unknown | mitochondria | no |
| A15624580 | RING-U-box superfamily protein | 1.48 | 2.48 | 1.48 | unknown | zinc ion binding | nucleus | yes |
| A15626540 | PYRIDOXINE BIOSYNTHESIS 2 (PDX2); encodes a protein predicted to function in tandem with PDX1 to form glutamine amidotransferase complex with involved in vitamin B6 biosynthesis. PDX2 is predicted to function as glutaminase within the complex. | 1.23 | 2.05 | 1.23 | vitamin B6 biosynthesis | hydrolase activity | cytoplasm | no |

Table S6. Time specific genes responsive to irradiance increase; genes more than 2.0-fold down-regulated in Col-0 when comparing plants exposed to increased irradiance to control plants, at 1, 3.5 or 25 hours after the irradiance increase and differentially (P=0.05) down-regulated between two or three time-points when comparing 1, 3.5, and 25 hours. Unlogged fold changes are shown, grey shaded values are <2.0 fold down-regulated, green shading indicates accession-specific difference in expression present in control conditions independent of irradiance increase. Time spec. in cont. = Time-specific difference in expression present in control conditions, independent of irradiance increase

| Gene ID | Gene name and description | C-1 | C-3.5 | C-25 | GO Biological Process | GO Molecular Function | GO Cellular Component | Time spec. in cont. |
|-----------|---|------|-------|------|--------------------------------------|---------------------------------------|-----------------------|---------------------|
| A1504955 | Encodes an alanine which is involved in alanine degradation and assimilation. Gene expression was induced when alfalfa was added to the medium. The insertion mutant, alan m2-1, did not grow well on the MS medium where alanine, instead of ammonium nitrate, was supplied. | 0.97 | 0.32 | 0.71 | alanine degradation and assimilation | hydrolase activity | endoplasmic reticulum | no |
| A1503300 | Involved in mucilage formation. Mutants form columbia and colar cell wall architecture of the mucilage cells resembles wild-type. However, mutant seeds completely lack seed coat mucilage. This mutation appears to represent a later step in the biosynthesis of mucilage. Encodes a beta-galactosidase involved in beta-D-galactose biosynthesis. Member of Glycoside Hydrolase Family 35 | 0.80 | 0.40 | 0.64 | carbohydrate metabolism | beta galactosidase | extracellular region | no |
| A1965590 | Encodes a protein with beta-hexosaminidase activity. Located on the plasma membrane. | 0.72 | 0.46 | 0.73 | carbohydrate metabolism | beta-hexosaminidase activity | plasma membrane | no |
| A1503350 | Legume lectin family protein. FUNCTIONS IN: carbohydrate binding, binding | 0.47 | 0.48 | 0.86 | carbohydrate metabolism | lectin family protein | chloroplast | yes |
| A1971880 | Sucrose transporter gene induced in response to nematodes; member of Sucrose-proton symporter family. | 0.81 | 0.62 | 0.65 | carbohydrate metabolism | sucrose-proton symporter | plasma membrane | no |
| A1453320 | Pectin lyase-like superfamily protein | 0.64 | 0.67 | 0.44 | carbohydrate metabolism | unknown | extracellular region | no |
| A1969530 | Member of Alpha-Egagranin Gene Family. Naming convention from the Egagranin Working Group (Kende et al., Plant Mol Bio). | 0.76 | 0.41 | 0.49 | cell organization | cell organization and biogenesis | extracellular region | no |
| A1501420 | Encodes PIN-FORMED 4 (PIN4), a putative auxin efflux carrier that is localized in developing and mature root meristems. It is involved in the maintenance of embryonic auxin gradients. A role for PIN4 in generating a sink for auxin below the shoot apical meristem has been reported. PIN4 is expressed in the shoot apical meristem. In the root, PIN4 is detected around the quiescent center and cells surrounding it, and localizes basally in protovascular cells. | | | | cell organization | cell organization and biogenesis | unknown | no |
| A15028120 | Encodes an auxin influx transporter. AUX1 resides at the apical plasma membrane of protoxylem cells and at highly dynamic subpopulations of Golgi apparatus and endosomes in all cell types. AUX1 action in the lateral root cap and/or root meristem is essential for auxin-induced lateral root emergence. Shoot supplied ammonium targets AUX1 and inhibits lateral root emergence. | 0.67 | 0.59 | 0.48 | cell organization | cell organization and biogenesis | plasma membrane | no |
| A15026010 | Member of Alpha-Egagranin Gene Family. Naming convention from the Egagranin Working Group (Kende et al., 2004, Plant Mol Bio). Involved in the formation of nematode-induced syncytia in roots of Arabidopsis thaliana. | 0.48 | 0.16 | 0.31 | cell organization | cell organization and biogenesis | extracellular region | no |
| A1901120 | Encodes a condensing enzyme. KCS1 (3-ketocyclo-CoA synthase 1) which is involved in the critical fatty acid elongation process in wax biosynthesis. | 0.69 | 0.59 | 0.44 | cell organization | fatty acid biosynthetic | endoplasmic reticulum | no |
| A1452340 | Encodes a vacuolar processing enzyme belonging to a novel group of cysteine proteases that is expressed in vegetative organs and is up-regulated in association with various types of cell death and under stressed conditions. They are essential in processing seed storage proteins and for mediating the susceptible response of toxin-induced cell death. | 0.94 | 0.44 | 0.80 | cell organization | hydrolase activity | extracellular region | no |
| A14916520 | autophagy 8f (ATG8F) | 0.90 | 0.40 | 0.90 | cell organization | microtubule cytoskeleton | unknown | no |
| A1490260 | Encodes a G2a2 and Cu2+-binding protein. N-terminal myristylation on glycite 2 appears to enable it to associate tightly with the plasma membrane. Recombinant PCA11 interacts strongly with phosphatidylinositol (3,5)-bisphosphate (PIPins) (3,5)P2 and PIPins (3,4,5)P2 (see also PIPins and PIPins(4,5)). It also interacts with cardanolin (Cdn) in a calcium-dependent manner. Cardanolin is a protein that is induced in Arabidopsis roots by the plant hormone ethylene and the PIPinase, PCA11 has an apparent Kd of 10 uM for Cu2+ and can bind six ions per protein. Transcript levels for PCA11 first fall and then rise following exposure to CuCl2. Mannitol, sorbitol, and the ligand oligopeptide also increase expression. | 0.88 | 0.39 | 0.49 | cell organization | microtubule cytoskeleton organization | chloroplast | no |
| A1490150 | Belongs to one of the LOM (LOST MERISTEMS) genes: AT2G46160 (LOM1), AT2G46230 (LOM2), and AT2G46150 (LOM3). LOM1 and LOM2 promote cell differentiation at the periphery of shoot meristems and help to maintain their polar organization; | 0.49 | 0.97 | 0.57 | cell organization | transcription factor activity | nucleus | no |

| Gene ID | Gene name and description | C-1 | C-25 | GO Biological Process | GO Molecular Function | GO Cellular Component | Time spec. in cont. |
|------------|--|------|------|-----------------------|----------------------------------|-----------------------|---------------------|
| A1503210 | Encodes a member of xyloglucan endotransglucosyltransferases (XTHs) that catalyze the cleavage and molecular rearrangement of the cell wall. Gene is expressed in shoot apical region, flower buds, flower stalks and internodes bearing flowers. | 0.88 | 0.48 | 0.81 | transferrase activity | extracellular region | no |
| A15032370 | Encodes a lysyl-containing receptor-like kinase LYK4. Shares overlapping function with LYK5 in mediating chitin-triggered immune responses. | 0.76 | 0.43 | 0.72 | kinase activity | chloroplast | no |
| A15045330 | Encodes a sucrose-rich repeat arabinogalactan protein-kinase that is expressed ubiquitously. FL52 is involved in MAP kinase signaling pathway of flagellin, a protein elicitor of the defense response. FL52 is detected for degradation by the bacterial chitinase ligase AvrPtb3. | 0.78 | 0.47 | 0.56 | protein binding | plasma membrane | yes |
| A15049080 | Encodes a protein with cysteine protease inhibitor activity. Overexpression increases tolerance to abiotic stresses (for salt, osmotic, cold stress). | 0.83 | 0.44 | 0.76 | protease activity | extracellular region | no |
| A11508970 | ATP binding cassette transporter. Localized to the plasma membrane in uninfected cells. In infected leaves, the protein is induced in a salicylic acid-dependent manner. Required for plasma resistance. Has Cd transporter activity (Cd2+ extrusion pump) and contributes to heavy metal resistance. | 0.91 | 0.43 | 1.03 | transporter activity | plasma membrane | no |
| A15049220 | Undersideraxin conserved protein | 1.04 | 0.34 | 0.75 | defense response | chloroplast | no |
| A15049420 | Disease resistance protein (TIR-NEIS class) | 0.86 | 0.37 | 0.71 | defense response | cytoplasm | no |
| A115011920 | Histone H3 K4-specific methyltransferase SET7/9 family protein | 0.67 | 0.44 | 0.62 | DNA modification | chloroplast | no |
| A13042610 | Plays role in DNA-damage repair/abscission. Partially complements RepA-phenotypes. | 0.76 | 0.45 | 0.71 | DNA repair | chloroplast | no |
| A15056860 | Encodes a cytochrome N-glucosyltransferase that is involved in cytokinin homeostasis and cytokinin response in plants through cytochrome N-glucosylation. Expression is induced by ABA, mannitol and drought stress. Analysis of overexpressors and loss of function mutants indicate a role in response to osmotic and drought stress. | 0.58 | 0.38 | 0.52 | transferase activity | unknown | no |
| A15021460 | Glutaredoxin family protein | 0.48 | 0.30 | 0.33 | electron transport activity | cytoplasm | yes |
| A15046130 | Encodes a putative transcription factor (MYB4b) that functions to regulate flavonoid biosynthesis primarily in cotyledons. | 0.44 | 1.04 | 0.70 | transcription factor activity | nucleus | no |
| A14603400 | Encodes a GH3-related gene involved in red light-specific hypocotyl elongation. Analysis of sense and antisense transgenic plants suggests that DFL2 is located downstream of red light signal transduction and determines the degree of hypocotyl elongation. The gene encodes a gamma-glutamyl transferase (AKA gamma-glutamyl transferase, EC 2.3.2.2) that is located in vascular tissues (predominantly phloem) of leaves and is involved in the degradation of glutathione. The encoded enzyme also migrates oxidatively as a by metabolizing GSSG (oxidized form of GSH - glutathione) in the apoplast. | 0.71 | 0.88 | 0.48 | signal transduction | cytoplasm | no |
| A14508640 | Bifunctional inhibitor/lipid-transfer protein/seed storage 2S albumin superfamily protein | 0.87 | 0.46 | 0.85 | transferase activity | extracellular region | no |
| A15045180 | Bifunctional inhibitor/lipid-transfer protein/seed storage 2S albumin superfamily protein | 0.90 | 0.41 | 0.68 | lipid binding | chloroplast | no |
| A14622490 | Bifunctional inhibitor/lipid-transfer protein/seed storage 2S albumin superfamily protein | 1.52 | 0.43 | 1.05 | lipid remodelling | extracellular region | yes |
| A15046460 | Pyruvate cyclase/acyltransferase and lipid transport superfamily protein | 0.38 | 0.17 | 0.23 | lipid binding | cytoplasm | no |
| A15023080 | GDSL_m00f esterase/acyltransferase/lipase. Enzyme group with broad substrate specificity that may catalyze acyltransferase or hydrolase reactions with lipid and non-lipid substrates. | 0.87 | 0.44 | 0.81 | lipid remodelling | chloroplast | no |
| A11509390 | GDSL_m00f esterase/acyltransferase/lipase. Enzyme group with broad substrate specificity that may catalyze acyltransferase or hydrolase reactions with lipid and non-lipid substrates. | 0.67 | 0.43 | 0.84 | transferase activity | chloroplast | no |
| A13041370 | GDSL_m00f esterase/acyltransferase/lipase. Enzyme group with broad substrate specificity that may catalyze acyltransferase or hydrolase reactions with lipid and non-lipid substrates. | 0.96 | 0.50 | 0.59 | transferase activity | extracellular region | no |
| A14617460 | Encodes a class II HD-ZIP protein that regulates meristematic activity in different tissues, and that it is necessary for the correct formation of the gymnosium. | 0.78 | 0.50 | 0.69 | transcription factor activity | nucleus | no |
| A15048720 | Encodes a plasma membrane-located ferri-chelate reductase. Its mRNA is expressed in green aerial tissues (shoot, flower and cotyledon) in a light- and cell differentiation-specific manner. | 0.79 | 0.27 | 0.55 | ferri-chelate reductase activity | membrane | no |
| A15048790 | Encodes a plasmalemma-glucose-6-phosphate dehydrogenase that is sensitive to reduction by DTT and whose mRNA is more prevalent in developing organs but absent in the root. | 0.67 | 0.37 | 0.77 | oxidation-reduction activity | chloroplast | no |
| A15049060 | Glucose-methanol-choline (GMC) oxidoreductase family protein | 0.76 | 0.34 | 0.50 | oxidation-reduction | unknown | no |
| A14627710 | member of CYP709B | 0.89 | 0.41 | 0.90 | oxidation-reduction | unknown | no |
| A15046690 | Encodes a thioneodon (WCRRC1) localized in chloroplast stroma. Contains a WCRRC motif. | 0.84 | 0.41 | 0.78 | oxidation-reduction | chloroplast | no |
| A15048800 | Thioredoxin superfamily protein | 0.75 | 0.30 | 0.68 | oxidation-reduction | cytoplasm | no |

| Gene ID | Gene name and description | C-1 | C-25 | GO Biological Process | GO Molecular Function | GO Cellular Component | Time spec. in cont. |
|-----------|--|------|------|-----------------------------------|-------------------------------|-----------------------|---------------------|
| A1923290 | sinapoylglucose:malate sinapoyltransferase. Catalyzes the formation of sinapoylmalate from sinapoylglucose. Mutants accumulate excess sinapoylglucose. | 0.86 | 0.67 | phenylpropanoid metabolic process | transferase activity | extracellular region | no |
| A1594190 | Encodes phytochrome kinase substrate 4, a phytochrome signaling component involved in photoperiodism. It is phosphorylated in a pH-dependent manner in vitro. Phosphorylation is transient and regulated by a type 2 protein phosphatase. | 0.65 | 0.62 | photoreceptor activity | phytochrome signaling | plasma membrane | no |
| A11918810 | phytochrome kinase substrate-related | 0.66 | 0.43 | photoreceptor activity | unknown | plasma membrane | no |
| A14927440 | light-dependent NADPH-prochlorophyllide oxidoreductase B | 0.88 | 0.34 | photosynthesis | chlorophyll biosynthesis | chloroplast | no |
| A19241560 | unknown protein | 0.89 | 0.36 | photosynthesis | photosynthesis | nucleus | no |
| A1924430 | Encodes LIGHT-HARVESTING CHLOROPHYLL-PROTEIN COMPLEX 1 (LHC1B1) | 0.95 | 0.28 | photosynthesis | light harvesting | chloroplast | no |
| A1924320 | NAD(P)-binding Rossmann-fold superfamily protein | 0.84 | 0.44 | photosynthesis | NAD binding | unknown | no |
| A19249350 | FAD/NAD(P)-binding oxidoreductase family protein | 0.65 | 0.49 | photosynthesis | NAD binding | chloroplast | no |
| A14919170 | chloroplast-targeted member of a family of enzymes similar to nine-cis-epoxycarotenoid dioxygenase | 0.43 | 0.29 | photosynthesis | oxidation-reduction | chloroplast | yes |
| A15941190 | Encodes GLK2. Glk2-like 2, one of a pair of partially redundant nuclear transcription factors that regulate chloroplast development in a cell-autonomous manner. GLK1, Glk2-like 1, is encoded by A19240570. GLK1 and GLK2 regulate the expression of the photosynthetic apparatus. | 0.54 | 0.60 | photosynthesis | transcription factor activity | nucleus | no |
| A15925190 | encodes a member of the ERF (ethylene response factor) subfamily B-6 of ERF/AP2 transcription factor family. The protein contains one AP2 domain. There are 12 members in this subfamily including RAP2.11. | 0.54 | 0.32 | photosynthesis, drought response | transcription factor activity | nucleus | no |
| A19118950 | Phototropic-responsive NPH3 family protein | 0.67 | 0.57 | protein ubiquitination | transport | plasma membrane | no |
| A19119770 | Member of a family of proteins related to PUP1, a purine transporter. May be involved in the transport of purine and purine derivatives such as cytokinins, across the plasma membrane. | 0.78 | 0.48 | purine transport | transport | component of membrane | no |
| A19177760 | Encodes NITRATE REDUCTASE (NMR1), the cytosolic minor isoform of nitrate reductase (NR). Involved in the first step of nitrate assimilation, it contributes about 15% of the nitrate reductase activity in shoots. Similar to myohypoxanthine oxidoreductases at the N-terminus, and to FAD/NAD-binding cytochrome reductases at the C-terminus. Cofactors: FAD, heme iron (cytochrome B-557), and molybdenum-sulfur. | 0.50 | 0.73 | response to nitrate | nitrate assimilation | mitochondria | no |
| A11968840 | RAV2 is part of a complex that has been named 'regulator of the (H+)-ATPase of the vacuole and endosomal membranes' (RAVE) | 1.25 | 0.47 | response to nitrate | regulator of the (H+)-ATPase | nucleus | no |
| A19243320 | Induced by Salicylic acid, virus, fungus and bacteria involved in the phytoalexin synthesis pathway. Independent of NPR1 for induction. Induced by salicylic acid, salicylic acid, and salicylic acid. The protein has a weak ability to catalyze the formation of the P-aminobenzoate-glucose ester in vitro. But, UGT75B1 appears to be the dominant PABA acylglucosyltransferase in vivo based on the results of the in vivo assay. The substrates (S) of UGT74F2 are not known, but mutant plants lacking UGT74F2 have a decreased level of SAG and SGE. | 0.77 | 0.44 | response to nitrate | transferase activity | cytoplasm | no |
| A15944655 | RESPONSE TO LOW SULFUR 4 (LSU4) | 0.78 | 0.99 | response to sulfur | unknown | nucleus | yes |
| A19241560 | Encodes a salmodin-regulated Ca2+/NATPase that improves salt tolerance in yeast. Localized to the vacuole. Lesion mimicking mutation in Arabidopsis thaliana. Growth and survival of Arabidopsis thaliana can be suppressed by nutritional supplements that increase anion levels (e.g. 15 mM Nitrate, Chloride, or Phosphate). | 0.75 | 0.31 | salt tolerance | transport | vacuole | yes |
| A11969490 | Encodes a member of the MAC transcription factor gene family. It is expressed in floral primordia and upregulated by AP3 and P1. Its expression is associated with leaf senescence. | 1.00 | 0.31 | senescence | transcription factor activity | nucleus | no |
| A11917350 | Encodes the brassinosteroid signaling component BE3 (BR-ENHANCED EXPRESSION 3). Positively modulates the allele dominance syndrome in Arabidopsis seedlings. | 0.82 | 0.39 | shade avoidance | transcription factor activity | nucleus | no |

Chapter 5

Natural variation in photosynthetic response to increased irradiance explained by epistatic interaction between *PHOSPHATIDIC ACID PHOSPHOHYDROLASE 2* and *ASPARAGINE SYNTHETASE 2*

ABSTRACT

Photosynthetic light use efficiency is inevitably connected with the incoming growth irradiance level. Specifically acclimation to increased irradiance is crucial, as increased incoming light levels lead to the production of reactive oxygen species (ROS) that are harmful to the integral cellular structures of the plant that could be lethal when persistent. The combination of genome wide association mapping (GWAS) and linkage mapping allowed the dissection of part of the genetic complexity and the underlying genetic variation explaining phenotypic variation in photosynthetic efficiency response to increased irradiance. It revealed an epistatic relation between two genes, *PHOSPHATIDIC ACID PHOSPHOHYDROLASE 2 (PAH2)* and *ASPARAGINE SYNTHETASE 2 (ASN2)*. PAH2 acts in membrane lipid remodelling in response to phosphate starvation, and ASN2 acts in detoxifying excess ammonium levels by transporting it via asparagine from source to sink organs. Three natural alleles could be found in the GWAS population for both genes. This study shows strong indications for the involvement of specific combinations of these *PAH2* and *ASN2* natural alleles in keeping high photosynthesis efficiencies in response to increased irradiance.

INTRODUCTION

A plant's capacity and efficiency to convert incoming light and CO₂ to biomass and O₂ through the process of photosynthesis is of major interest to present society with increasing population and rising CO₂ levels, as photosynthesis uses CO₂ (and light) to produce plant biomass (Long et al., 2015). Many possible targets have been identified to manipulate for increasing photosynthetic efficiency (Evans, 2013). These targets range from the canopy level to the thylakoid membrane level and from light capture to CO₂ conductance (Evans, 2013). Understanding genetic variation for photosynthesis and its response to fluctuating environments is crucial, as it will allow plant breeders to select for the photosynthetically best performing genotypes in an early stage, which might lead to faster growth and higher yields in later stages (Athanasidou et al., 2010). This study focusses on the process of light use efficiency, a trait that is inevitably connected with the incoming growth irradiance level (Van Rooijen et al., 2015). The ability of a plant to acclimate to fluctuations in irradiances is of major importance to maintain high photosynthetic rates over those conditions (Walters, 2005; Leister, 2012; Van Rooijen et al., 2015). Specifically acclimation to increased irradiance is crucial, as increased incoming light levels lead to the production of reactive oxygen species (ROS) that are harmful to the integral cellular structures of the plant, which could be lethal when persistent (Powles, 1984).

A sudden increase in growth irradiance provokes a regulatory response in the plant's metabolism within seconds, called photoprotection (Demmig-Adams and Adams, 1992). When the high irradiance level persists for longer time, photosynthetic acclimation will change the composition of mesophyll cells in terms of their proteins, lipids, pigments, and other cofactors involved in electron transport and reactive-oxygen species metabolism (Bailey et al., 2004; Walters, 2005). Increasingly more research is being performed to identify the genetic loci that are regulating these (sub-) processes in photosynthetic acclimation (Suorsa et al., 2012; Albrecht-Borth et al., 2013; Jin et al., 2014; Van Rooijen et al., 2015). The natural allelic variants of the genes underlying such loci can be applied for breeding for photosynthetic performance (Van Rooijen et al., 2015).

Natural allelic variants result from random mutations of the genomic DNA sequence. Phenotypic variation in a trait such as photosynthetic light use efficiency can be related to variation at the genome sequence level, which allows the identification of the associated genes (Alonso-Blanco et al., 2009; Flood et al., 2011; Alonso-Blanco and Méndez-Vigo, 2014). To do this, *Arabidopsis thaliana* is the model species of choice, because of its

well-described genetics, its wide availability of natural accessions, and the ability to exploit it in genome wide association studies (GWAS), (Atwell et al., 2010; Bergelson and Roux, 2010; Ogura and Busch, 2015). GWAS are performed in populations consisting of a large number of natural isogenic lines collected from nature, that have genetically adapted to different ecological conditions over thousands of years. In order to genetically map quantitative traits to the genome, GWAS take advantage of the recombination events that have accumulated over all those generations resulting in a high mapping resolution (Bergelson and Roux, 2010). An important aspect to consider when performing GWAS is Linkage Disequilibrium (LD), which is the non-random association of alleles at different loci, affecting the number of recombination events occurring through time (Kim et al., 2007). When LD is only over short lengths in the genome, it requires a very high density of genotyping to find causal loci for a phenotypic trait in GWAS. Also the interpretation of association peaks in GWAS is not straightforward as population structure can lead to the occurrence of false positive associations; and the presence of causal alleles with low allele frequency, the presence of multiple alleles having the same phenotype, or the presence of a genetic interaction between two loci can lead to hidden heritability (Korte and Farlow, 2013). Epistasis is an example of a genetic interaction between two loci, where the phenotypic effect of one allele one locus is obscured by the genotype at another locus (Bateson, 1909).

A more traditional method to link phenotypic variation to genetics is to do family mapping (Lander and Botstein, 1989). For this, two different accessions are crossed, the heterozygous plant that arises is self-fertilized, and the segregating offspring are phenotyped for the trait of interest, and genotyped for enough molecular markers to cover the genome. Less genetic complexity exists within family mapping compared to GWAS, as it deals with the presence of only two alleles per locus, coming from the two parents, increasing the mapping power. While family mapping provides the mapping power that is lacking in GWAS, it has a very low resolution because it depends upon the limited number of recombination events that have occurred in one (or a few) generation(s). The combination of GWAS and family mapping has proven to be a successful strategy in unravelling complex plant genetics (Keurentjes et al., 2011; Motte et al., 2014).

This study uses the combination of genome wide association mapping and family mapping to identify the underlying genetic variation of phenotypic variation in photosynthetic efficiency response to increased irradiance. A GWAS population and an experimental F2 population were phenotyped for photosynthesis efficiency response to increase irradiance. Both these populations revealed to be segregating for the trait of

interest and were used for genetic mapping. Genetic mapping revealed two epistatic quantitative trait loci (QTLs) on chromosome 5 were associated to photosynthesis efficiency levels after one hour of irradiance stress in both populations. Haplotype and expression analyses revealed the underlying genes were *PHOSPHATIDIC ACID PHOSPHOHYDROLASE 2 (PAH2)* and *ASPARAGINE SYNTHASE 2 (ASN2)*, acting in the conversion of membrane phospholipids to galactolipids and the removal of excess ammonia, respectively.

This study identifies genetic epistasis, a factor that is thought to be limiting the power in genetic mapping of complex traits with many underlying genes (Korte and Farlow, 2013). Additionally, it reveals three natural alleles for both PAH2 as well as three natural alleles for ASN2 are underlying natural variation in photosynthesis efficiency in response to increased irradiance.

MATERIALS AND METHODS

Plant material and growth conditions

A set of 344 accessions was used for GWAS, as described in Chapter 3 of this thesis. The accessions S96 and SLSP30 were crossed, and one F1 plant was self-fertilized to produce an F2 mapping population. Of this F2 population, 306 plants were grown, genotyped for 384 single nucleotide polymorphisms (SNPs), and phenotyped for photosynthesis response to excess irradiance.

With the aid of the re-sequence data of the 1001 genomes project as described in (<http://1001genomes.org/>), the accessions Baa-1, Ga-0, S96, Uk-1, and Got-7 were selected to represent the ASN2-PAH2-genotype 'ASN2-5,6,7-PAH2-1,2,3,5,6'; the accessions Ra-0, Old-1, Yo-0, Faeb-4, and Broet1-6 to represent the genotype "ASN2-5,6,7-PAH2-4"; accessions Fei-0, Kin-0, Ren-1, and Chat-1 to represent the genotype "ASN2-2,3-PAH2-1,2,3,5,6"; and the accessions Ts-1, LL-0, Com-1, and SLSP30 to represent the genotype "ASN2-2,3-PAH2-4".

The T-DNA insertion knock-out line *asn2-1* (SALK_043167) was kindly donated by the laboratory of Dr. Akira Suzuki (INRA Centre de Versailles-Grignon, France). The double T-DNA insertion knock-out line *pah1pah2* (originated from SALK_042970 and SALK_047457) was kindly donated by the laboratory of Dr. Peter Eastmond (Department of Plant Biology and Crop Science, Rothamsted Research, United Kingdom).

All plants were grown and phenotyped as described in Chapter 3 of this thesis

Genetic analysis

Genome wide association analysis was performed for Φ_{PSII} -values averaged per accession (at least three replicates were used to determine the average value), combined with the 215,000 SNP database for 360 accessions (Kim et al., 2007), using a mixed model analysis software package, written within the R project environment for statistical computing (<https://www.r-project.org/>).

For analysis of the F2 population derived from the cross between S96 and SLSP30, all 306 F2 plants were genotyped for 384 SNPs using Illumina's GoldenGate Genotyping with VeraCode Technology. A genetic map was created using Joinmap 4 (Van Ooijen, 2006). Multiple QTL Mapping (MQM) was performed using MapQTL6 (Van Ooijen, 2009).

Haplotypes were generated based on all SNPs in the promoter and coding regions of the two candidate genes using the re-sequence data of 173 accessions, which are those out of the 344 GWAS accessions of which re-sequence data were available at the time of the analysis (<http://1001genomes.org/>). Those haplotypes that occurred in >4% of the 173 accessions were then associated with photosynthetic phenotypes. Haplotypes that resulted in significantly different photosynthetic response to increased irradiance (based on t-test) were further compared per SNP for association with the phenotype.

Gene expression analysis

Gene expression was determined using quantitative reverse transcriptase PCR (qRT-PCR) as described in Chapter 3 of this thesis. The primers used are listed in table S1.

Lipid profiling

Rosettes of *Arabidopsis* plants grown for 33 days in $600 \mu\text{mol m}^{-2} \text{s}^{-1}$ growth irradiance were harvested and flash-frozen in liquid nitrogen. Frozen rosettes were broken into pieces and immersed for 15 minutes in 2 ml isopropanol with 0.01% butylated hydroxytoluene (BHT), preheated to 80 °C. Subsequently, 1 ml chloroform and 0.4 ml water were added, mixed, and the solution was agitated for 1 hour at room temperature. Lipid extracts were transferred to glass tubes with Teflon-line screw-caps; 2 ml chloroform/methanol (2:1) with 0.01% BHT was added to the remaining leaf pieces, and the solution was agitated for 30 minutes at room temperature. The second lipid extract was added to the first extract and the extraction procedure was repeated until all leaf pieces became white. Subsequently, 0.5 ml of 1M potassium chloride was added to the combined extract, mixed and centrifuged to separate the lipids from the proteins and carbohydrates. The upper phase was discarded, 0.5 ml water was added to the lower phase, mixed and centrifuged. The upper phase was discarded again, and the lower phase was dried with nitrogen stream.

The dried lipid extracts were analysed by thin layer chromatography (TLC) coupled with gas-liquid chromatography (GLC).

RESULTS

Identification of two QTLs for the photosynthesis response to increased irradiance

Using 344 accessions, Φ_{PSII} was measured repeatedly three times a day in a climate chamber where the growth irradiance was increased from 100 to 550 $\mu\text{mol m}^{-2} \text{s}^{-1}$, at the onset of the photoperiod, on day 25 after sowing. The first measurement in high light was performed one hour after the irradiance increase and the second measurement 3.5 hours after the irradiance increase. Genome wide association studies (GWAS) were performed to associate these first two high light measurements with 215,000 SNPs spread over the genome of Arabidopsis. By setting the significance threshold for association peaks to a $-10\log(p)=4$, thirteen peaks of association were identified one hour after the irradiance increase and seventeen peaks 3.5 hours after the irradiance increase, with an overlap of 6 peaks (Fig. 1A and 1B). All association peaks are specific for high light, none of them appeared before the irradiance increase (Fig. S2).

In order to select the QTLs for further analysis, two GWAS accessions (S96 and SLSP30) were crossed that were polymorphic for all SNPs above our association threshold. One F1-plant was self-fertilized, and the F2 population was grown under the same conditions as the GWAS population and Φ_{PSII} values were measured at the same time points. A genetic map was created for the F2 population (Supplementary Fig S1), and QTLs for Φ_{PSII} values at the same time points as in the GWAS were mapped using family mapping (Fig 1C and 1D).

Figure 1. Mapping of photosynthesis response to excess irradiance in *Arabidopsis thaliana* (A + B) $-\log_{10}(P\text{value})$ for 215,000 single nucleotide polymorphisms (SNPs) in a genome-wide association mapping panel of 344 natural accessions (A) one hour after increased growth irradiance, and (B) three and a half hours after increased growth irradiance. The colours blue and pink distinguish the 5 chromosomes from left to right, the black dotted line represents a significance threshold arbitrarily set at $-\log_{10}(P\text{value})=4$, the red dots are SNPs that are associated with the phenotype at $-\log_{10}(P\text{value}) \geq 4$, the numbers indicate distinct association peaks; (C + D) LOD scores of 384 SNPs represented as a red line though each chromosome in an F2 mapping population arisen from a cross between two natural accessions S96 and SLSP30 (C) one hour after increased growth irradiance, and (D) three and a half hours after increased growth irradiance. The black dotted line represents a significance threshold set with a permutation test at $\text{LOD}=3$.

At one hour after the irradiance increase, the F2 population QTL map showed five QTLs. The QTL on chromosome 2 and the QTL on chromosome 4 were unstable when comparing the one hour time-point to the 3.5 hour time-point; the QTL on chromosome 3 and the other QTL on chromosome 5 were also found when Φ_{PSII} was measured before the irradiance increase (Fig. S3). Only the QTL at the end of chromosome five is specific for high light and is stable when compared to 3.5 hours after the increase (QTL2, Fig. 1C). At 3.5 hours after the irradiance increase, one more QTL on chromosome 5 was

associated with Φ_{PSII} , also specific for high light (QTL1, Fig. 1D). QTL1 disappeared on day 2 after the irradiance increase and QTL2 disappeared on day 3 after the irradiance increase (Fig. S3). QTL1 and 2 were both also found in the GWAS-profiles (Fig. 1A and 1B); with the notification that 3.5 hours after the irradiance increase these two peaks were just below our arbitrary threshold of $-\log_{10}(p)=4$ (Fig. 1B). However, both QTLs reappeared in subsequent time-points (Fig. S2). The location of the associated SNPs above $-\log_{10}(p)=4$ in GWAS or above LOD=3 in F2 family mapping for both QTLs are shown in Table 1.

Table 1. Location of the associated SNPs above $-\log_{10}(p)=4$ in GWAS or above LOD=3 in F2 family mapping for (A) QTL1 and (B) QTL2

| A | | B | |
|---|-------------------------------------|---|-------------------------------------|
| QTL1 | | QTL2 | |
| Location of associated SNPs on chromosome 5 | | Location of associated SNPs on chromosome 5 | |
| above - $\log_{10}(p)=4$ in GWAS | above LOD=3 in family mapping | above - $\log_{10}(p)=4$ in GWAS | above LOD=3 in family mapping |
| 17,186,178 | 14,853,688 | 25,956,134 | 25,149,877 |
| 17,187,071 | 16,105,691 | 25,963,073 | 25,802,730 |

The LD region in GWAS around the associated SNPs of QTL1 is 8 kb (Kim et al., 2007), which encompasses three genes according to TAIR10 (www.arabidopsis.org), which are At5g42860, At5g42870, and At5g42880. Of these three genes, only at5g42870 has a described gene function, encoding *PHOSPHATIDIC PHOSPHOHYDROLASE 2 (PAH2)*. Haplotype analysis and mutant analysis was performed for *PAH2* to prove its involvement in natural variation for photosynthesis efficiency, as described in the next paragraphs.

The LD region in GWAS around the associated SNPs of QTL2 is 50 kb (Kim et al., 2007), which encompasses twenty genes according to TAIR10, ranging from At5g64855 until At5g65020. This association peak also arose after performing GWAS in a time-course manner (Chapter 3 of this thesis). *In silico* prioritization of these twenty candidate genes

based on gene ontology, gene co-expression, gene expression in the vegetative rosette, and the presence of segregating polymorphisms in the coding sequence followed by mutant analysis highlighted At5g65010, encoding *ASPARGINE SYNTHETASE 2 (ASN2)*, as the best candidate underlying QTL2 (Chapter 3 of this thesis). Haplotype analysis and functional analysis was performed for *ASN2* to prove its involvement in photosynthesis efficiency.

Haplotype analysis

Haplotype analysis among 173 re-sequenced accessions for the *PAH2* gene resulted in 8 different alleles with allele frequencies $\geq 4\%$ (Fig. 2A). No clear difference in photosynthesis efficiency response to increased irradiance was discovered between these alleles (Fig. 2B). Sequence analysis revealed several polymorphisms were common among alleles 1, 2, 3, 5, and 6, indicated by the blue arrows in Fig. 2A. Additionally, alleles 7 and 8 showed sequence similarity (Fig. 2A). Allele 4 showed distinct from either of the other alleles, indicated by the red arrows in Fig. 2A. Grouping the 173 re-sequenced accessions according to their *PAH2* alleles based on this observation (*PAH2-1,2,3,5,6* versus *PAH2-7,8* versus *PAH2-4*) revealed higher photosynthesis efficiency in response to increased irradiance for accession with the *PAH2-1,2,3,5,6* allele (Fig. 2C).

Haplotype analysis among 173 re-sequenced accessions for *ASN2* resulted in 7 different alleles with allele frequencies $\geq 4\%$ (Fig. 2D), of which allele 2 resulted in significantly lower photosynthesis efficiency compared to the other alleles (Fig. 2E). In addition, also allele 4 has lower photosynthesis efficiency specifically at later time points (Fig. 2E). Close analysis of the sequences of alleles led to the hypothesis that the following two polymorphisms in *ASN2* are associated to the observed photosynthesis differences: the guanine (G) of alleles 5, 6 and 7 (*ASN2-5,6,7*) in the fifth intron of the coding sequence (position 25,970,333 bp) led to relatively high photosynthesis efficiency; and the cytosine (C) of alleles 2 and 3 (*ASN2-2,3*) in the tenth exon of the coding sequence (position 25,971,571 bp), leads to relatively low photosynthesis efficiency (Fig. 2D). We did not observe genotypes in which both polymorphisms were present together. Grouping the 173 re-sequenced accessions according to their *ASN2* alleles based on this observation (*ASN2-1,4* versus *ASN2-2,3* versus *ASN2-5,6,7*) revealed different photosynthesis efficiency in response to increased irradiance between accessions with the *ASN2-2,3* compared to accessions with the *ASN2-5,6,7* allele (Fig. 2F).

Figure 2 (on next page). In silico analysis of 173 re-sequenced Arabidopsis accessions (1001 genomes)

(A) Eight most abundant alleles and frequency (%) for the PAH2 gene. Gene orientation is 3' to 5'; two splice variants are indicated. SNPs differing from the Col-0 reference genome sequence (allele 8) are marked. Polymorphisms indicative of possible association with natural variation in photosynthesis efficiency are marked in red and blue; (B) Average photosynthesis efficiencies (Φ_{PSII}) (\pm SE) of accessions grouped by the eight alleles of PAH2 before and after an increase in irradiance; (C) Median Φ_{PSII} one hour after increased irradiance of accessions grouped by the identity of the two SNPs that represent best the different alleles in the PAH2 gene (N=118 for PAH2-1,2,3,5,6; N=23 for PAH2-7,8; N=32 for PAH2-4). Box = 25th and 75th percentiles; bars = min and max values; letter over bar indicates significant differences between groups in T-test series; (D) Seven most abundant alleles and frequency (%) for the ASN2 gene. Gene orientation is 5' to 3'; two splice variants are indicated. SNPs differing from the Col-0 reference genome sequence (allele 1) are marked. Polymorphisms associated with natural variation in photosynthesis efficiency are marked in red (E) Average photosynthesis efficiencies (Φ_{PSII}) (\pm SE) of accessions grouped by the seven alleles of ASN2 before and after an increase in irradiance. (F) Median Φ_{PSII} one hour after increased irradiance of accessions grouped by the identity of the two causative SNPs in the ASN2 gene (N=79 for ASN2-1,4; N=27 for ASN2-2,3; N=67 for ASN2-5,6,7). Box = 25th and 75th percentiles; bars = min and max values; letter over bar indicates significant differences between groups in T-test series.

Epistasis

Analysis of the effect of the different *PAH2* and *ASN2* alleles revealed that the variation at the *PAH2* gene only affected photosynthesis efficiency in high light when *ASN2-2,3* was present (Fig. 3A). Oppositely, the variation at the *ASN2* gene only affected photosynthesis efficiency in high light when *PAH2-4* was present (Fig. 3A). The same epistatic relation was observed in the F3 population arisen from five F2 plants grouped by their genotypes concerning the *PAH2* and *ASN2* alleles (Fig. 3B).

Figure 3. Epistasis

Median Φ_{PSII} one hour after increased irradiance of (A) the natural accessions; and (B) the F3-families arisen from the F2 population, grouped by their genotypes concerning the *PAH2* and *ASN2* alleles; Box = 25th and 75th percentiles; bars = min and max values; number over or under bar indicates statistical outliers; letter over bar indicates significant differences between groups in ANOVA.

Mutant analysis

For both the *PAH2* as the *ASN2* gene T-DNA insertion knock-out mutants are available. These were studied to further investigate the involvement of *PAH2* and *ASN2* in photosynthesis efficiency. A knock-out of *ASN2* in the Col-0 background (*asn2-1*) affected photosynthesis efficiency at the first two days after the increase in growth irradiance (Fig. 4). A knock-out of *PAH2* is expected to have no obvious phenotype as *PAH2* is known to be redundant with *PAH1*, and both genes need to be mutated to disrupt their function (Eastmond et al., 2010). The double knock-out *pah1pah2* did not affect photosynthesis efficiency on the first two days after increased growth irradiance, but after the third and fourth day it acclimated less than control (Fig. 4). The lines *asn2-1* and *pah1pah2* were crossed and the triple mutant *asn2-1pah1pah2* was selected in its progeny using mutant specific markers. The triple mutant did not affect photosynthesis efficiency in any time point compared to Col-0 (Fig. 4). To confirm the effect of the different natural alleles identified in haplotype analysis, quantitative complementation was tried for the *asn2-1* mutant, but failed to identify *ASN2* as causal for the identified QTL (Chapter 3 of this thesis).

Figure 4. Mutant analysis of *asn2-1*, *pah1pah2*, and *asn2-1pah1pah2*.

Representative photosynthetic (Φ_{PSII}) phenotypes for *Arabidopsis* Col-0, and the mutants *asn2-1*, *pah1pah2*, and *asn2-1pah1pah2*, grown for 24 days in $100 \mu\text{mol m}^{-2} \text{s}^{-1}$ growth irradiance and subsequently 6 days in $550 \mu\text{mol m}^{-2} \text{s}^{-1}$ growth irradiance, measured from day 23 (first day of measurement) until day 31, at four time-points per day; $AV \pm SE$.

Gene expression

Gene expression of *PAH2* and *ASN2* in natural accessions as well as in T-DNA knock-out insertion lines was studied to provide evidence for the involvement of both genes as underlying the two QTLs found for photosynthesis efficiency, as well as to find an explanation for the epistatic interaction between these two QTLs. There is no difference in expression of *ASN2* when comparing *ASN2-567* vs *ASN2-23* under LL, whereas *ASN2-567* is higher expressed than *ASN2-23* under HL (Fig. 5A). Additionally, the presence of the *PAH2-1,2,3,5,6* allele leads to down-regulation of *ASN2* in response to increased irradiance (Fig. 5A). Expression of *PAH1* nor *PAH2* in response to increased irradiance could not be associated to any allelic combination (Fig 5B and 5C).

In the double mutant *pah1pah2*, the expression response to increased irradiance of *ASN2* is similar as in Col-0 (Fig 6A). When *ASN2* is no longer functional (in the *asn2-1* mutant), the expression of *PAH2* is increased in response to increased irradiance, whereas the expression of *PAH1* is not (Fig 6B and 6C). In the double mutant *pah1pah2*, there is still some *PAH1* expression implying *pah1* is not a knock-out, but a knock-down. In the triple mutant *asn2-1pah1pah2*, the expression response to increased irradiance of *PAH1* is increased compared to Col-0 (Fig 6B).

Figure 5. Expression analysis of ASN2, PAH1, and PAH2 in natural Arabidopsis accessions

Expression of (A) ASN2, (B) PAH1, and (C) PAH2 measured as relative expression to the averaged value of the housekeeping genes (\pm SE) by qRT-PCR three hours after excess irradiance induction (HL) as well as in control conditions (LL), in natural Arabidopsis accessions grouped by their genotypes concerning the PAH2 and ASN2 alleles. Expression was measured in four accessions randomly chosen per genotype (Baa-1, Ga-0, S96, Uk-1, and Got-7 to represent the genotype 'PAH2-1,2,3,5,6-ASN2-5,6,7'; Ra-0, Old-1, Yo-0, Faeb-4, and Broet1-6 to represent the genotype "PAH2-4-ASN2-5,6,7"; Fei-0, Kin-0, Ren-1, and Chat-1 to represent the genotype "PAH2-1,2,3,5,6-ASN2-2,3"; and Ts-1, LL-0, Com-1, and SLSP30 to represent the genotype 'PAH2-4-ASN2-2,3'; four biological replications were used per accessions, two plants were pooled per biological replication. The * indicates significant ($P=0.05$) difference between expression in high light conditions (HL) versus expression in control conditions (LL).

HL response affects membrane lipid remodelling

PAH1 and *PAH2* convert phosphatidic acid into di-acyl-glycerol (DAG), releasing orthophosphate as by-product (Eastmond et al., 2010). This is a small step in the complex physiological process of remodelling phospholipids to the galactolipids monogalactosyl diacylglycerol (MGDG) and digalactosyl diacylglycerol (DGDG) (Nakamura et al., 2009). The lipid remodelling functions in releasing orthophosphate (Pi) from phospholipids to overcome phosphate starvation (Moellering and Benning, 2011), as well as to acclimate photosynthesis efficiency to excess light (Nilsson et al., 2011). *PAH2* and *ASN2* were hypothesized to epistatically function in balancing the intracellular Pi concentrations.

Gene expression of MGDG and DGDG synthase genes in the *asn2-1* and *pah1pah2* T-DNA knock-out insertion lines was studied to test if *ASN2* can take over the lipid remodelling function of *PAH1/2* in providing balanced Pi concentrations. No effect of increased irradiance (HL) was observed after three hours on expression of the MGDG and DGDG synthase genes compared to control conditions (LL) in Col-0, nor in the single mutant *asn2-1* or the double mutant *pah1pah2* (Fig 6D, 6E, 6F, 6G, and 6H), while all tested MGDG and DGDG synthase genes were upregulated after three hours in response to increased irradiance in the triple mutant *asn2-1pah1pah2* (Fig 6D, 6E, 6F, 6G, and 6H). The absent induction of the MGDG and DGDG synthase genes in Col-0 implies that three hours after irradiance increase is too short to activate the process of lipid remodelling to release orthophosphate. The induction of the MGDG and DGDG synthase genes in the triple mutant is correlated with the induction of *PAH1* in the triple mutant (Fig. 6B), implying *PAH1* activates lipid remodelling within three hours after the irradiance increase only when both *ASN2* and *PAH2* are knocked-out, indicating the significance of the lipid remodelling process in acclimation to increase irradiance.

To confirm the significance of lipid remodelling, lipid profiling in the *asn2-1* and *pah1pah2* T-DNA knock-out insertion lines as well as in two natural accessions with contrasting *ASN2* and *PAH2* genotypes was performed. Additionally, it was still not clear if *ASN2* could take over the lipid remodelling function of *PAH1/2*. Four lipids were quantified, two of which are galactolipids (monogalactosyldiacylglycerol [MGDG] and digalactosyldiacylglycerol [DGDG]) and two are phospholipids (phosphatidylcholine [PC] and phosphatidylglycerol [PG]). The molar ratios (the share of one class of lipids in the total amount of lipids) of MGDG were similar in the double mutant *pah1pah2* and the triple mutant *asn2-1pah1pah2*, both were lower than in Col-0 (Fig. 7A). This observation

confirms the lipid remodelling function of *PAH1* and *PAH2*, and implies *ASN2* cannot take over the lipid remodelling function of *PAH1/2*. The molar ratio of DGDG was similar in all genotypes measured (Fig. 7B), implying the effect of *PAH1/2* on lipid remodelling does not affect DGDG synthesis. Of the phospholipids, the molar ratios of PC were similar in the double mutant *pah1pah2* and the triple mutant *asn2-1pah1pah2*, both were higher than in Col-0 (Fig. 7A). The molar ratios of PG were similar in all genotypes measured. No differences were measured between Col-0 and the natural Arabidopsis accessions representing the 'PAH2-1,2,3,5,6-ASN2-5,6,7' and 'PAH2-4-ASN2-2,3' genotypes (Fig. 7).

Figure 6. Expression analysis of *ASN2*, *PAH1*, *PAH2*, *MGD1*, *MGD2*, *MGD3*, *DGD1*, and *DGD2* in Col-0, *asn2-1*, *pah1pah2*, and *asn2-1pah1pah2*.

Expression of (A) *ASN2*, (B) *PAH1*, (C) *PAH2*, (D) *MGD1*, (E) *MGD2*, (F) *MGD3*, (G) *DGD1*, (H) *DGD2* measured as relative expression to the averaged value of the housekeeping genes (\pm SE) by qRT-PCR three hours after increased irradiance induction (HL) as well as in control conditions (LL), in Col-0, and in the T-DNA knock-out mutant lines *asn2-1*, *pah1pah2*, and *asn2-1pah1pah2*. The * indicates significant ($P=0.05$) difference between expression in high light conditions (HL) versus expression in control conditions (LL).

Figure 7. Molar ratios of major lipid classes in *Arabidopsis* mutants and in natural accessions grown for 33 days in $600 \mu\text{mol m}^{-2} \text{s}^{-1}$ growth irradiance.

Molar ratio of (A) monogalactosyldiacylglycerol (MGDG); (B) digalactosyldiacylglycerol (DGDG); (C) phosphatidylcholine (PC); and (D) phosphatidylglycerol (PG) in whole rosettes of *Arabidopsis* Col-0, in the T-DNA knock-out mutant lines *asn2-1*, *pah1pah2*, and *asn2-1pah1pah2*, and in one natural accession representing the 'PAH2-1,2,3,5,6-ASN2-5,6,7' genotype and one natural accession representing the 'PAH2-4-ASN2-2,3' genotype, grown for 3 days in $600 \mu\text{mol m}^{-2} \text{s}^{-1}$ growth irradiance, ($AV \pm SE$; $N=3$). Letter above bars indicate significant differences.

Geographic distribution

In order to find any pattern of evolutionary adaptation, the coordinates of the GWAS accessions were mapped according to their genotypes concerning the *PAH2* and *ASN2* alleles (Fig. 8). The geographical distribution of European GWAS accessions grouped by the identity of the *ASN2* and *PAH2* alleles shows an east-west gradient with the photosynthetically best performing combination of alleles '*PAH2*-1,2,3,5,6-*ASN2*-5,6,7' (green) in central and eastern Europe, the two combinations of one positive and one negative photosynthetically performing allele '*PAH2*-4-*ASN2*-5,6,7' and '*PAH2*-1,2,3,5,6-*ASN2*-2,3' (combined in one colour: yellow) are mainly found in France and Spain and the photosynthetically worst performing '*PAH2*-4-*ASN2*-2,3' (red) found in France and Spain as well as in Britain (Fig. 9).

Figure 8. Geographic distribution.

Geographic distribution of European GWAS accessions grouped by their genotypes concerning the *PAH2* and *ASN2* alleles: '*PAH2*-1,2,3,5,6-*ASN2*-5,6,7' (green) and '*PAH2*-4-*ASN2*-2,3' (red), plus the two heterozygous alleles '*PAH2*-4-*ASN2*-5,6,7' and '*PAH2*-1,2,3,5,6-*ASN2*-2,3' (combined in one colour: yellow).

DISCUSSION

By combining GWAS and F2 family mapping, we identified two QTLs on chromosome 5, which have an epistatic interaction for photosynthesis efficiency response to increased irradiance. Using the high resolution of GWAS we identified the underlying genes *ASPARAGINE SYNTHASE 2 (ASN2)* and *PHOSPHATIDIC ACID PHOSPHOHYDROLASE 2 (PAH2)* as the best candidates associated to natural variation in photosynthesis efficiency response to increased irradiance.

Epistatic interaction and allelic variation for *PAH2* and *ASN2* underlying two QTLs for photosynthesis response to increased irradiance

In the GWAS, the association peak for *PAH2* (QTL1) as well as the peak for *ASN2* (QTL2) came above our arbitrary threshold at one hour after the irradiance increase (Fig. 1A), both were below the threshold at 3.5 hours after the irradiance increase (Fig. 1B), and both re-appeared in subsequent time-points (Fig. S2), revealing the QTLs depend on the environment. In the F2 family mapping, the QTL for *ASN2* appeared within one hour after the irradiance increase and it was still present after 3.5 hours, whereas the QTL for *PAH2* appeared only 3.5 hours after the increase in irradiance (Fig. 1C and 1D). Similar as in GWAS, also in the F2 family mapping the two QTLs re-appeared in subsequent time-points (Fig. S3), revealing 'genotype x environment' interaction (El-Soda et al., 2014).

Both for *ASN2* and *PAH2*, haplotype analysis revealed three distinct alleles (Fig. 2). The *PAH2-1,2,3,5,6* and the *PAH2-4* alleles reveal distinct polymorphisms compared to the *PAH2-7,8* allele (the Col-0 allele). The combination of the polymorphisms SNPs of the *PAH2-1,2,3,5,6* allele and the polymorphisms of the *PAH2-4* allele does not occur in the population. Similarly, the *ASN2-5,6,7* and *ASN2-2,3* alleles reveal distinct polymorphisms compared to the *ASN2-1,4* allele (the Col-0 allele), and the combination of polymorphisms does not occur in the population. The fact that some combinations of polymorphisms do not occur suggests that two independent mutational events happened one after the other (Fig. 9). The combination of the *PAH2-4* and *ASN2-2,3* allele is photosynthetically unfavourable (Fig 2), probably leading their low frequency in the population (Fig 9). Many more polymorphisms are present in *PAH2* than in *ASN2*, suggesting *PAH2* is functionally less important than *ASN2*, as functionally less important loci evolve at a faster rate (Kimura and Ohta, 1974). The fact that there is another gene with similar function as *PAH2*, which is *PAH1*, supports this suggestion.

Figure 9. Overview of (A) *PAH2* and (B) *ASN2* alleles

The occurrence in the population (N) and the effects on photosynthesis efficiency (Φ_{PSII}) of the alleles relative to each other are shown.

The combination of GWAS mapping and F2 family mapping allowed the discovery of an epistatic relationship between the two loci covering the *PAH2* and *ASN2* genes (Fig. 3). The epistasis was more pronounced in the F2 population than in the GWAS population (Fig. 3), explained by the less allelic diversity of the two loci in the F2 population. In the F2 population both loci have two possible alleles (either parent A or parent B), whereas in the GWAS population there are at least three alleles per locus (Fig. 2). Epistasis limits the effect of genetic variation in one locus to the presence of a specific allele at another locus, reducing the amount of accessions to determine the effect size of the QTL, limiting the genetic signal. Additionally, when the two loci are on the same chromosome there is genetic linkage, lowering the recombination events between the two loci, distorting the distribution of frequencies of allelic combinations of the two loci. Both these limitations contribute to epistasis often being seen as a limiting factor in performing GWAS, as it lowers the association of QTLs (Korte and Farlow, 2013). The epistatic effect results in the combination of two alleles (*PAH2-4* and *ASN2-2,3*) that gives a less favourable photosynthesis efficiency, which indicates that although the other alleles function sufficiently to take over the effect of a less functional allele at the other locus, this is not the case when a less functional allele occurs at both loci, implying both genes function in a similar way in photosynthesis.

***PAH2* and *ASN2* balance intracellular Pi concentrations for maintaining high photosynthesis efficiency**

PAH1 and *PAH2*, which act redundantly (Eastmond et al., 2010), are needed for remodelling phospholipids to galactolipids (Nakamura et al., 2009). The lipid remodelling functions in releasing orthophosphate (Pi) from phospholipids to overcome phosphate starvation (Moellering and Benning, 2011), as well as to acclimate photosynthesis efficiency to excess light. In photosynthesis, Pi is necessary for ATP synthesis, activation

of Rubisco, and for export of triose phosphate (Dietz and Foyer, 1986). Within the process of lipid remodelling *PAH1* and *PAH2* convert phosphatidic acid into di-acylglycerol (DAG), releasing orthophosphate as by-product (Eastmond et al., 2010). DAG is the direct substrate for synthesis of monogalactosyl diacylglycerol (MGDG), MGDG being a substrate for the synthesis of digalactosyl diacylglycerol (DGDG). DGDG is important for the integrity of the chloroplast protein-import apparatus (Chen and Li, 1998), explaining the significance of the lipid remodelling process for keeping high photosynthetic efficiencies. However, MGDG but not DGDG molar ratios were affected in the *asn2-1* and *pah1pah2* mutants, suggesting not DGDG but another galactolipid is significant for the response to increased irradiance (Fig 7). It is suggested the MGDG is converted to the negatively charged sulfoquinovosyl diacyldiglycerol (SQDG), that creates a charge balance to the photosynthetic membranes that is overcharged as a result of the excess light (Chapter 4 of this thesis).

ASN2 is one of three members of the small asparagine synthetase gene family in Arabidopsis (Lam et al., 1998), which converts the amino acid aspartic acid (Asp) to asparagine (Asn). Asn acts as an important nitrogen storage and transport compound in plants, particularly when carbon supplies are limited (Lam et al., 1998). The expression of *ASN2* is absent in dark-adapted plants, and is induced after a switch from dark to light in an ammonium-dependent way (Lam et al., 1998; Wong et al., 2004). Oxidative stress following excess irradiance increases the cellular concentrations of ammonium by either increased rates of photorespiration or induced rates of proteolytic activity, breaking down oxidatively damaged proteins (Sweetlove et al., 2002; Foyer et al., 2003; Kumagai et al., 2011; Bittsánzky et al., 2015). Genotypic variation for increased rates of ammonia emission in relation to photorespiration has been found in rice (Kumagai et al., 2011), but this relationship could not be found in Arabidopsis (Gaufichon et al., 2013). However, the proteolytic activity that results from oxidative stress does increase ammonia levels in Arabidopsis (Sweetlove et al., 2002). As excess ammonium is toxic to plants, the produced ammonium is normally immediately re-used for new organic and amino acid biosynthesis (Foyer et al., 2003). Ammonium levels were found to accumulate in high light irradiance in *asn2*-knock-out lines but not in Col-0 wild type, indicating that *ASN2* is needed for proper removal of excess ammonium upon high light irradiance, either by degradation or by reallocation (Wong et al., 2004; Gaufichon et al., 2013). *ASN2* is particularly known to play a role in the export of nitrogen from source organs to sink organs via the phloem (Gaufichon et al., 2013). Our study identifies genetic variation in the *ASN2* gene to explain part of the natural variation for photosynthesis efficiency in response to increased irradiance, suggesting that balancing nitrogen metabolism is

closely associated to the efficiency of photosynthesis acclimation. We explain the significance of balancing nitrogen metabolism for keeping high photosynthetic efficiencies by the need of removing of excess ammonium levels that rise in source organs in response to oxidative stress (Britto and Kronzucker, 2002; Bittsánszky et al., 2015).

ASN2 was found to have an epistatic interaction with *PAH2* regarding its effect on photosynthesis efficiency. The *ASN2* protein is an ATP-pyrophosphatase, which means its synthetase domain binds Mg^{2+} -ATP and aspartate to catalyse the production of an β -aspartyl-AMP intermediate and pyrophosphate (PPI), (Larsen et al., 1999). The β -aspartyl-AMP intermediate is subsequently converted into asparagine via a chemical reaction with ammonia, and the PPI is hydrolysed into two orthophosphate (Pi) molecules (Larsen et al., 1999). Also *PAH1* and *PAH2* release Pi as by-product when converting phosphatidic acid into di-acyl-glycerol (DAG) (Eastmond et al., 2010). We hypothesize the epistatic relation between *ASN2* and *PAH2* is explained by the fact that both genes catalyse reactions where Pi molecules are released as by-products. We suggest *ASN2* and *PAH2* are redundant in their role of balancing intracellular Pi concentrations to maintain high photosynthesis efficiency in response to increased irradiance. The epistatic effect between *ASN2* and *PAH2* explains the unsuccessful quantitative complementation test to confirm the effect of the *ASN2* natural alleles on photosynthesis efficiency (Chapter 3 of this thesis). The use of quantitative complementation is ambiguous because of the confounding effects of epistasis (Service, 2004; Turner, 2014). Transgenic complementation is needed to confirm to allelic effects of *PAH2* and *ASN2* on photosynthesis efficiency response to increased irradiance.

PAH2 is known to be redundant to *PAH1* (Eastmond et al., 2010). There is still some *PAH1* expression in the double mutant *pah1pah2*, implying *pah1* is not a knock-out, but a knock-down (Fig. 6B). In the triple mutant *asn2-1pah1pah2*, the expression response to increased irradiance of *PAH1* is increased compared to Col-0 (Fig 6B). The induction of the MGDG and DGDG synthase genes in the triple mutant (Fig 6D, 6E, 6F, 6G, and 6H) is correlated with the induction of *PAH1* in the triple mutant (Fig. 6B), implying *PAH1* activates lipid remodelling within three hours after the irradiance increase only when both *ASN2* and *PAH2* are knocked-out. This suggests *PAH1* function is only needed when both *PAH2* and *ASN2* are knocked-out, confirming the redundant role of *ASN2* and *PAH2* in acclimation to increased irradiance.

Several observations lead to the conclusion that *ASN2* acts earlier in the acclimation response to increased irradiance than does *PAH2*, i.e. the QTL for *ASN2* appears earlier

in the F2 family mapping (Fig. 1), the knock out mutant *asn2-1* mainly affects photosynthesis efficiency on the first two days after increase in irradiance whereas the double knock-out mutant *pah1pah2* mainly affects photosynthesis efficiency on the last few days after increase in irradiance (Fig. 4), and the MGDG and DGDG synthase genes were not induced yet after 3 hours (Fig 6). The triple mutant *asn2-1pah1pah2* does not affect photosynthesis efficiency compared to wild type Col-0 (Fig. 4), suggesting a third pathway for photosynthetic acclimation takes over when the first two are knocked out.

Both the expression of *ASN2* and *PAH2* are not induced in expression after irradiance increase (Fig. 5), implying their individual effects are on translational or functional level. However, the epistatic relation between them is expression-based, as accessions that have *PAH2-1,2,3,5,6* allele show reduced *ASN2* expression three hours after increased irradiance (Fig. 5A), leading to the conclusion that *PAH2* downregulates the expression of *ASN2* when *PAH2* gets functional after the irradiance increase by taking over the function of *ASN2* in photosynthetic acclimation to increased irradiance. This expression-based relation is supported by the observation that *PAH2* expression in response to irradiance increase is induced when *ASN2* is knocked out (Fig. 6C), i.e. when one functional pathway is omitted another takes over. The fact that *ASN2* expression is not induced to compensate when *PAH2* is knocked-out, can be explained by the fact that the pathway in which *ASN2* acts functions earlier in time than the pathway in which *PAH2* acts. We explain this by the fast rise of reactive oxygen species and subsequently ammonia, that has to be dissipated and transported to sink organs by *ASN2* (producing Pi as side product). When the formation of reactive oxygen species are being prevented by subsequent metabolism such as formation of anthocyanins (Asada, 2006), the release of Pi needed for higher photosynthetic rates gets taken over by *PAH2*. *PAH2* gets activated for the release of extra Pi, as well as for keeping the integrity of the photosynthetic membranes by providing galactolipids.

Allelic effects on the epistatic interaction between *PAH2* and *ASN2*

We conclude the *ASN2-5,6,7* allele, leading to relatively high photosynthesis efficiency acclimation (Fig. 2), is capable of providing enough Pi so that lipid remodelling by *PAH2* for extra Pi remobilization is not needed. The *ASN2-1,4* allele (the Col-0 allele) is not capable of providing enough Pi so that lipid remodelling is needed, as seen in reduced conversion of phospholipids to galactolipids in the *pah1pah2* double mutant where the *ASN2-1,4* allele cannot take over the lipid remodelling function of mutant *PAH2* (Fig. 7). The *ASN2-2,3* allele is also not capable of providing enough Pi, as seen in apparent

effects of *PAH2* allelic variation only when the *ASN2-2,3* allele is present (Fig. 3). The observation of *PAH2* allelic variation only being apparent when the *ASN2-2,3* allele is present, suggests the *ASN2-3* allele is less functional than the *ASN2-1,4* allele. Oppositely, the *PAH2-1,2,3,5,6* allele, leading to relatively high photosynthesis efficiency acclimation (Fig. 2), provides enough Pi, leading to down-regulation of *ASN2* (Fig. 5A). Both the *PAH2-4* allele and the *PAH2-7,8* allele (the Col-0 allele) do not show this effect, being less functional (Fig. 5A and Fig. 6A). The observation of *ASN2* allelic variation only being apparent when the *PAH2-4* allele is present, suggest the *PAH2-4* allele is less functional than the *PAH2-7,8* allele (the Col-0 allele).

The European geographic distribution of natural accessions grouped according to the presence of the allelic combinations for *ASN2* and *PAH2*, shows a longitudinal gradient with the photosynthetically best performing allelic combination (*PAH2-1,2,3,5,6* and *ASN2-5,6,7*) found more in eastern Europe (Fig. 8). This is indicative of a selective force acting on photosynthesis regulation; future evolutionary ecological studies are necessary to find out what this force is.

This study shows strong indications for the involvement of *PAH2* and *ASN2* in keeping high photosynthesis efficiencies in response to increased irradiance. Ultimate proof of the *PAH2-1,2,3,5,6* allelic effects and the *ASN2-5,6,7* allelic effects for increasing photosynthesis efficiencies should be gained by future transgenic complementation studies.

ACKNOWLEDGEMENT

We thank Dr. Akira Suzuki, INRA Centre de Versailles-Grignon, France, for his kind donation of the *asn2-1* mutant seeds. We thank Dr. Peter Eastmond, Department of Plant Biology and Crop Science, Rothamsted Research, United Kingdom for this kind donation of the *pah1pah2* mutant seeds. We thank Prof. Dr. Maarten Koornneef for reading of the manuscript. This project was carried out within the research programme of BioSolar Cells, co-financed by the Dutch Ministry of Economic Affairs.

Figure S1. Genetic map of F2 population

The five chromosomes of *Arabidopsis thaliana* are shown from left to right.

Figure S2. Genetic mapping in the GWAS population with Φ_{PSII} values measured (A) before; (B) 6.5 hours; (C) 25 hours; (D) 28.5 hours; (E) 31.5 hours; (F) 49 hours; (G) 52.5 hours; and (H) 55.5 hours after the increase in growth irradiance.

$-\log_{10}(Pvalue)$ for 215,000 single nucleotide polymorphisms (SNPs) in a genome-wide association mapping panel of 344 natural accessions. The colours blue and pink distinguish the 5 chromosomes from left to right, the black dotted line represents a significance threshold arbitrarily set at $-\log_{10}(Pvalue)=4$, the red dots are SNPs that are associated with the phenotype at $-\log_{10}(Pvalue)\geq 4$

Figure S3. Genetic mapping in the F2 population with Φ_{PSII} values measured (A) before; (B) 6.5 hours; (C) 10.5 hours; (D) 25 hours; (E) 28.5 hours; (F) 31.5 hours; (G) 35.5 hours; (H) 49 hours; (I) 52.5 hours; (J) 55.5 hours; and (K) 59.5 hours after the increase in growth irradiance.

LOD scores of 384 SNPs are represented as a red line through each chromosome. The black dotted line represents a significance threshold set with a permutation test at $LOD=3$.

Chapter 6

General Discussion

Photosynthesis efficiency variation under light stress

Improving the efficiency of photosynthesis is a grand opportunity to increase food and climate security in a world with ever increasing population and rising CO₂ levels (Zhu et al., 2010; Lawson et al., 2012; Long et al., 2015). Photosynthesis is the basis of all life on earth, it provides carbohydrates for plant growth, and through the edible plants indirectly also for animal and human growth. Additionally, it provides the oxygen to the air we all so desperately need to breathe, thereby using CO₂ as a substrate, reducing the rising atmospheric CO₂ concentrations.

Photosynthesis is a complex process both on the physiological as well as the molecular level. Many possible targets have been identified to manipulate for increasing photosynthetic efficiency. These targets range from the canopy level to the level of enzymatic kinetic properties, and from light harvesting to CO₂ conductances (Evans, 2013). However, improving the maximum efficiency of light energy conversion seems surprisingly difficult (Zhu et al., 2008), resulting in the idea that plant photosynthesis has been optimized during evolution (Leister, 2012). This thesis negates this idea, as it reveals several genetic targets for direct improvement of light use efficiency of photosystem II (Φ_{PSII}).

The success of manipulations for enhancing photosynthetic efficiency depends on the environmental conditions in which it is measured. In the laboratory, photosynthesis is usually measured in stable environmental conditions, i.e. the plant has completely acclimated to its environment. In nature, environments are more dynamic due to the daily moving of the sun and clouds, as well as seasonal temperature changes. Extensive regulation is known for photosynthetic responses to such environmental fluctuations (Walters, 2005; Minagawa, 2013; Dietz, 2015). In this thesis, a broader phenotypic distribution for photosynthesis efficiency was found among *Arabidopsis* accessions under light stress, as opposed to stable conditions (Chapter 2). However, the light stress effect on photosynthesis efficiency did not influence the heritability of the trait (Chapter 2), and QTLs could be found for photosynthesis efficiency both in low light conditions as well as in stressful high light conditions, although the number of quantitative trait loci (QTLs) increased after the onset of light stress (Chapter 3). The increase in phenotypic variation could have different biological reasons, first of which is that every accession has adapted its genome to the dynamic growth environment it was growing in the field, leading to more variation for responses to fluctuating environmental conditions as opposed to stable laboratory conditions. Furthermore, a step-wise increase in irradiance moves the leaf

from light limitation to light saturation, which is known to provoke regulatory physiological responses. The extra regulatory mechanisms are an additional source for potential variation. Plant photosynthesis has originated in a marine ecosystem lacking light and oxygen (Ting et al., 2002). Only when plants colonized land, they needed to evolve mechanisms to use and protect the photosynthesis system from damage by high light (Alboresi et al., 2010). As a result, less variation exists among land plants for photosynthetic functioning in low light, as opposed to high light, possibly explaining the observations on genetic variation. An additional explanation is the lack of genetic information of chloroplast genomes among the genotype data used in the genome-wide association studies (GWAS) approach, although the extent of natural variation in chloroplast genes is still unknown. Many genes encoding the structural components of the photosystems and light harvesting complexes are on the chloroplast genome, whereas the regulatory genes for photosynthetic responses are mainly encoded on the nuclear genome (Berry et al., 2013).

The use of natural variation to uncover the genetics of photosynthesis

Traditional plant breeding strategies depend on the existence of natural genetic variation for any trait of interest, which is exploited by intercrossing available germplasm, which can include wild relatives. Photosynthesis efficiency is a phenotypic trait not yet bred for specifically, mainly because it is difficult to measure and because of its genetic complexity. Before the start of the project of which the results are described in this thesis, significant efforts have been made to develop a high-throughput phenotyper for photosynthesis efficiency (Harbinson et al., 2012), solving the phenotyping issue. This photosynthesis phenotyper exists of a camera moving over a platform of growing plants, imaging the plants top view. Because it is a non-destructive measurement, plants can repeatedly be measured throughout the experiment, allowing the construction of time courses through development (Flood et al., 2016) or through a stress response (Chapter 3).

The identification of the true genes causal for a quantitative phenotypic trait such as photosynthesis efficiency, to potentially use for introducing beneficial new alleles crossing into commercial varieties, remains a difficult task. Entire germplasms could be screened for the presence of favourable alleles for a trait of interest by the use of marker assisted selection. For genetically complex traits, such as plant photosynthesis, it is difficult to select the underlying genes with the beneficial alleles because the phenotypic effect of

variations in sequence of a candidate gene are usually very small as one gene plays only a small part in the entire process (small effect size). Natural genetic variation for the major regulators of a process is uncommon, as their big effect size causes selection on these loci, resulting in the presence of only one allele in the population. Genetic mapping studies try to find associations between the phenotypes of interest and genetic loci (Quantitative Trait Loci, QTLs) throughout the entire genome. These studies usually reveal multiple QTLs per mapping experiment, reflecting the genetic variation present for the process that is studied. The underlying causal genes can be identified by mutagenesis and overexpression studies. Different mapping strategies have been developed over the years, using populations with different genetic layouts. These strategies range from family mapping in the progeny of a cross between two accessions (F2 or RIL populations), to a more genetically complex situation in the progeny of a cross between multiple accessions (Ampril population or Magic population), to an even more complex genetics in a population of natural accessions (GWAS population), (Kover et al., 2009; Atwell et al., 2010; Bergelson and Roux, 2010; Huang et al., 2011; Keurentjes et al., 2011). Chapter 5 of this thesis shows that the combination of family mapping (crossing two accessions and genetically and phenotypically analysing the offspring of this cross) and GWAS mapping (exploiting multiple alleles and thousands of years of recombination events) allowed the discovery and explanation of an epistatic relationship between two loci (Chapter 5). Epistasis is often seen as a limiting factor in performing genetic mapping, as it lowers the association of QTLs (Korte and Farlow, 2013). Combining the two mapping approaches overcomes this problem, helping to dissect the genetic complexity of a trait with many different and connecting parts, such as photosynthesis efficiency.

In order to proceed from the QTL to the underlying causal gene, it is essential to know if the observed phenotypic differences are caused by expression differences in the causal gene or by structural differences in the encoded protein. Genome-wide transcriptomic analysis complements the mapping analysis in this (Chapter 4). Not much overlap was found between the QTLs found in the mapping study (Chapter 3) and the genes responsive to increased irradiance found in transcriptomic analysis (Chapter 4). However, they did point to candidates functioning in similar physiological pathways. The *YELLOW SEEDING 1 (YS1)* gene found in Chapter 3 acts in anterograde signalling between the nucleus and the chloroplast, regulating expression of chloroplast encoded genes. RNA metabolism and signalling between the nucleus and chloroplast was found as biological process to which many responsive genes to increased irradiance belong (Chapter 4). Additionally, many genes acting in the lipid remodelling process were upregulated by this

treatment (Chapter 4), to which also the gene encoding for phosphatidic acid hydrolase (*PAH2*), found to act epistatically to the gene encoding for asparagine synthetase (*ASN2*), (Chapter 5), belongs. None of the three genes that we characterized as genes underlying natural variation for photosynthesis response to increased growth irradiance (*YS1*, *ASN2*, *PAH2*), were found to be transcriptionally responsive to the irradiance increase themselves. However, finding enrichment of the same biological processes for these three genes in transcriptomics suggests the complementarity of the two approaches, which can be explained by the fact that associated polymorphisms in mapping studies are linked to underlying genes in the LD region, whereas transcriptional variation for a gene can be caused either *in cis* or *in trans*. Transcriptional variation caused *in trans* would not be uncovered in mapping studies, which apparently is the case for the photosynthetic regulatory genes. A proper confirmation study on this would be to do expression QTL (eQTL) mapping (Gibson and Weir, 2005; Gilad et al., 2008).

The journey from QTL to QTN

The huge advantage of GWAS over other mapping approaches is its high resolution as only few candidate genes underlie a QTL because of the small region of linkage disequilibrium (LD), (Korte and Farlow, 2013). In most of the published GWAS, the best associated single nucleotide polymorphism (SNP) from the dataset is not the causal SNP, however it does associate with the causal SNP through the LD. It is challenging to find the causal SNPs, as the SNPs in GWAS datasets are chosen because both of their alleles are common, and so cannot be in complete LD with a causal SNP driven to low frequency by selection (Wray et al., 2013), frequently referred to as hidden or missing heritability (Gibson, 2010; Brachi et al., 2011; Zuk et al., 2014). Whole genome re-sequence data for Arabidopsis (Weigel and Mott, 2009) solves this problem as it allows analysis of LD between the rare variant SNPs (absent in GWAS datasets) and the associated SNPs arisen from GWAS (Service et al., 2014), as seen in Chapter 3 and Chapter 5.

In quantitative genetics, different prioritizing methods for gene candidate lists have been developed (Huang et al., 2009; Feltus, 2014). A pathway-based expression set analysis is a way to examine for each candidate gene whether it is co-expressed with genes in the same functional pathway (Wang et al., 2007; Wang et al., 2010). In addition for each candidate gene it can be checked if the expression is mapped to the developmental stage and part of the plant under study (Schmid et al., 2005). Gene function prediction is a

method to determine the functional relation for each candidate gene by examining the gene ontology terms (Ashburner et al., 2000; Bargsten et al., 2014). All these approaches have their limitations, i.e. LD is calculated in a pre-determined group of re-sequenced accessions; transcriptomics is studied on certain time points/conditions; sequencing is done on a limited number of accessions. Therefore, even when a gene is causal in GWAS, it will never comply to all the selection criteria described above. However, the selective power of the different approaches can be improved by adding them together and prioritize the gene candidates by counting the number of selection approaches the candidate gene does comply to, as achieved in Chapter 3 of this thesis.

The use of T-DNA insertion lines to knock-out candidate genes is widely used in Arabidopsis to analyse gene functions (Alonso and Ecker, 2006). Its use in quantitative genetics is valuable to confirm the involvement of the gene candidate in the trait of study (Verslues et al., 2014). However, its use is not undisputed as there are limitations to its effectiveness (Wang, 2008), mainly because screening a large library of T-DNA homozygous lines for phenotypes of interest limits the researchers to only find effective knockouts of genes that have no redundancy and/or epistasis in the genome of the reference accession Columbia (Col), as most knock-outs are in the Col background.

The use of quantitative complementation is ambiguous because of the confounding effects of epistasis (Service, 2004; Turner, 2014). However, it has been applied successfully in Arabidopsis (Motte et al., 2014; Sanchez-Bermejo et al., 2014). Because of these confounding effects of epistasis, it is difficult to conclude if the absence of a successful complementation test is because the alleles are not causal, or because there is an epistatic effect (as for the *ASN2* gene in Chapter 3 and Chapter 5). However, as argued by (Turner, 2014), this problem can be surmounted by producing knock-outs in the accession under study instead of in Columbia-0 background. By using artificial micro RNAs (amiRNAs), we can reach this goal by knocking out the gene of interest in any genomic background (Weigel, 2012). In addition to amiRNAs, the CRISPR-Cas technological breakthrough in genomic manipulation facilitates the exact reproduction of natural alleles of a causal gene in different genomic backgrounds (Cong et al., 2013). Additionally, besides strengthening the quantitative complementation test, the CRISPR-Cas technology will also surmount the limitations of T-DNA insertion lines (mutation possible in different background breaking redundant/epistatic effects, multiple insertions in one genome, incomplete knockout, etc), (Voytas, 2013; Xing et al., 2014; Kumar and Jain, 2015).

The role of anterograde signalling in photosynthetic response to excess light

All the changes during photosynthetic acclimation are the result of signal-induced changes in gene expression, in a tight co-ordinated regulation between nuclear and chloroplast genes. This co-ordinated regulation is termed anterograde signalling in cases where nuclear signalling affects chloroplast gene expression and retrograde signalling in cases where chloroplast signalling affects nuclear gene expression. The anterograde signals are coming from trans-acting regulatory factors determining when and where in the chloroplast gene activation occurs. There are many distinct types and classes of trans-acting factors, ranging from nuclear factors interacting with light responsive gene promoters (such as the *YS1* promoter, Chapter 3), to nuclear encoded transcription factors controlling transcription of plastid encoded genes, and nuclear encoded proteins involved in post-transcriptional modification of chloroplast transcribed RNAs, such as the pentatricope-repeat (PPR) protein family to which *YS1* belongs. For chloroplast encoded photosynthesis genes, post-transcriptional regulation is the major regulatory mechanisms that determines the timing and location of expression (Berry et al., 2013). A very large number of nuclear-encoded RNA-binding proteins are present in plastids (Berry et al., 2013), and some of these are found to be responsive to light irradiance increase (Chapter 4). Several types of plastid-targeted RNA-binding proteins exist in plants, of which the class of PPR proteins is most enriched: the Arabidopsis genome encodes ~450 of them (Berry et al., 2013). PPR proteins are defined by the presence of a 35-amino-acid motif repeated in tandem up to 30 times (Schmitz-Linneweber and Small, 2008). They are separated into two major classes, the P- and PLS-class, based on the nature of their PPR motifs. The PLS-class is separated into two smaller subclasses, the E- and DYW-subclass, based on the presence of characteristic C-terminal motifs (Schmitz-Linneweber and Small, 2008). PPR proteins function in RNA translation, RNA editing, RNA splicing, and RNA stability of chloroplast and mitochondrial encoded genes (Schmitz-Linneweber and Small, 2008).

The chloroplast genome includes around 100 genes, the expression of which is essential for chloroplast development and photosynthetic functioning. Two types of RNA polymerases transcribe these genes: the nuclear-encoded polymerase (NEP) and the plastid-encoded polymerase (PEP). NEP transcribes the chloroplast housekeeping genes, whereas PEP transcribes the photosynthesis genes. PEP has a catalytic core consisting of RpoA, RpoB, RpoC1 and RpoC2, all encoded for by the chloroplast

genome. Additionally to the core, PEP associates with variable signalling factors determining its promoter specificity. These are known as sigma factors, and are all encoded by the nuclear genome (Hanaoka et al., 2003). The *YS1* gene encoding a PPR protein with a DYW motif is such a sigma factor, editing the *RpoB* transcript in the chloroplast, indirectly affecting transcription of chloroplast encoded photosynthesis genes and, remarkably, many chloroplast transfer-RNAs (tRNAs), (Zhou et al., 2009; Kindgren et al., 2012). The significance of PEP-transcribed tRNAs for photosynthetic functioning has been noted before, but remains elusive to date (Williams-Carrier et al., 2014).

High light induced photosynthetic activity has a strong effect on PEP-dependent plastid gene expression, generating a retrograde signal from the chloroplast to the nucleus (Kindgren et al., 2012). In response to increased irradiance, the plant thus can synchronize the expression of nuclear- and chloroplast-encoded photosynthetic via PEP, necessary to acclimate to environmental fluctuations. The identification of the *YS1* gene in this thesis as a genetic factor causing differences in photosynthetic efficiency (Chapter 3) and the finding of many RNA associated genes up-regulated in response to light increase of which some associated with photosynthetic efficiency (Chapter 4), reveals the significance of this regulatory mechanism in nature.

The role of internal phosphate levels in photosynthetic acclimation to excess light

In photosynthesis, orthophosphate (Pi) is necessary for ATP synthesis, activation of Rubisco, and for export of triose phosphate (Dietz and Foyer, 1986). As a consequence, P-starved leaves have low photosynthetic rates per unit leaf area, and high P-levels are needed for high photosynthetic rates. Increased rates of photosynthesis need a balance between the concentration of free Pi and phosphorylated intermediates (Stitt et al., 2010). When the release of Pi and the regeneration of ATP and NADPH lag behind the capture of light energy, i.e. in the case of excess irradiance, the imbalance leads to enhanced overreduction of the photosystems (Nilsson et al., 2011).

The internal Pi levels are regulated by the uptake of phosphate by the roots, as well as by internal mobilisation through (de)phosphorylation of internal structures (Abel et al., 2002). Pi is one of the least mobile macronutrients in the soil, due to precipitation with metal ions and binding to soil particles. As a result, high photosynthetic P-use efficiency in response to increased irradiance is gained from remobilizing Pi from internal structures, as shown in Chapters 4 and 5 of this thesis. This thesis shows that a major process for releasing Pi

to meet the increased photosynthetic rates in response to excess light, is the remodelling of chloroplast and cellular membranes, where phospholipids get converted to galactolipids (Chapters 4 and 5). An additional process working epistatically with the lipid remodelling is the removal of excess ammonium, thereby releasing Pi as a side product (Chapter 5). Different processes acting in concert to balance internal Pi levels, associated with different photosynthetic efficiencies in response to excess light, reveals the significance of this regulatory mechanism in nature.

Future prospective

Within biological research more and more focus is put on identifying genes, because with the genes in hand society believes we can not only improve crop production, but also animal and human health. This thesis contributes in finding genes underlying natural variation in photosynthesis efficiency in *Arabidopsis thaliana*, the genetic model organism for plants. As a model organism, *Arabidopsis* is significant for improving crop production, because it can act as an example for identifying molecular and physiological pathways that could potentially be modified in crops for their improvement. Understanding natural genetic variation in *Arabidopsis* is most interesting for breeding, as those genes are likely to be variable also in the germplasm of crops. Next step would now be to screen the germplasm of commercial crops for the presence of beneficial alleles of the genes causal for natural variation in photosynthesis efficiency response to increased growth irradiance identified in this thesis, by the use of marker assisted selection. Subsequent crossing of these beneficial alleles into commercial lines will allow analysis of its effect on photosynthesis in crops, as well as crop yield.

Additionally to improving photosynthesis efficiency, and ultimately crop yield, this thesis serves as an example for the dissection of complex genetics. Photosynthesis is a multi-step process for which many genes work together. This thesis shows also that the regulation of photosynthesis to light stress consists of many physiological and molecular pathways. This was already known, though at the genetic level, this thesis contributes to new insights. The combined use of GWAS, family mapping, and transcriptomics has helped in getting these results. These three approaches together yield huge and very rich datasets to analyse for a biologist, a task that a PhD student cannot completely fulfil within the provided time; the datasets provided in this thesis are still full with information not analysed in detail. Anyhow, I have shown the possibility of dissecting part of this complexity by a well-structured and targeted approach.

Summary

The efficiency of photosynthesis results from the composition and organization of the plant's internal structural components as well as the capability of response to environmental fluctuations. This thesis aims at identifying the genetic loci that are regulating the (sub-) processes in photosynthetic acclimation to increased irradiance levels, in order to obtain the genetic information useful to breed for photosynthetic performance. It uses genome wide association studies (GWAS) to reveal which genetic loci are being exploited in nature for keeping good photosynthetic performances in natural conditions. Phenotypic variation among natural accessions in photosynthetic light use efficiency response to increased growth irradiance is related to its variation in genetics in order to identify the associated genetic loci. In Chapter 2 is described which light environment reveals most natural variation in photosynthetic performance and for which photosynthetic parameter this is. It shows different *Arabidopsis* accessions display different photosynthetic responses to various light environments, well relatable to genetic differences. A candidate gene list for the direct response to increased growth irradiance was revealed after performing genome wide association analysis. Chapter 3 elaborates on the genome wide association results by visualizing the dynamics of the associated genetic loci over the time course of the photosynthetic response to increased irradiance. It shows it is possible to simplify the complexity of photosynthetic physiology as well as the genetic analysis in such way to confirm the causal genes underlying the associated loci, by confirming this for the *YELLOW SEEDLING 1 (YS1)* gene, a gene encoding a Pentatrigo-Peptide-Repeat (PPR) protein involved in RNA editing of plastid-encoded genes essential for photosystems I and II. Genetic variation for any trait can be on the transcriptional level or on the functional level. In Chapter 4, the gene regulation in three *Arabidopsis* accessions with contrasting photosynthesis efficiency responses to increased irradiance is studied. These differences in photosynthesis efficiency are associated to differences in activation extents of heat responsive genes as well as to differences in the presence of a gene activation pathway acting on membrane lipid remodelling, suggested to maintain balanced cellular phosphate concentrations. Chapter 5 confirms the significance of maintaining balanced cellular phosphate concentrations for photosynthesis efficiency responses to increased irradiance. It describes how genome wide association mapping and linkage mapping combine to reveal genetic epistatic interactions between *PHOSPHATIDIC ACID PHOSPHOHYDROLASE 2 (PAH2)*, phosphate metabolism gene) and *ASPARAGINE SYNTHETASE 2 (ASN2)*, nitrogen metabolism gene), both

acting in the delivery of orthophosphate in the chloroplast. In conclusion this thesis contributes new insights into the physiological and molecular pathways underlying photosynthesis responses to increased growth irradiances.

Samenvatting

De efficiëntie van fotosynthese is het gevolg van de compositie en organisatie van de interne structurele onderdelen van de plant, als wel het reactievermogen van de plant op veranderingen in omgevingsomstandigheden. Dit proefschrift heeft als doel genetische loci te identificeren die de (sub-) processen voor het acclimatiseren van fotosynthese in reactie op verhoogde licht intensiteit reguleren, ten einde deze verkregen genetische informatie te gebruiken voor het veredelen van fotosynthese prestaties binnen gewassen. Het onderzoek maakt gebruik van zogeheten genoom-wijde associatie studies (GWAS) om de genetische loci te onthullen die door de natuur binnen een soort variabel gehouden worden voor het ten alle tijde behouden van goede fotosynthese prestaties in afwisselende natuurlijke omgevingsomstandigheden. Fenotypische variatie tussen natuurlijke accessies (dezelfde soort planten afkomstig uit, en dus aangepast aan, een ander ecosysteem) in de reactie van fotosynthese efficiëntie op verhoogde licht intensiteit is voor dit onderzoek gerelateerd aan de genetisch variatie tussen deze accessies ten einde de geassocieerde genetische loci te identificeren. In hoofdstuk 2 wordt beschreven welke lichtomstandigheden de meeste waar te nemen variatie in fotosynthese efficiëntie onthullen en voor welke specifieke fotosynthese parameter dit is. Het laat verschillende reactievermogen met betrekking tot fotosynthese efficiëntie zien voor verschillende accessies van *Arabidopsis thaliana*, en laat zien dat deze verschillen goed te relateren zijn aan genetische variatie tussen deze accessies. Na het uitvoeren van GWAS, wordt een lijst met kandidaatgenen die verantwoordelijk kunnen zijn voor het initiële reactievermogen op verhoogde lichtintensiteit gegeven. In hoofdstuk 3 wordt verder ingegaan op de resultaten van de GWAS door de dynamica van geassocieerde genetische loci te analyseren tijdens een tijdsspanne waarin fotosynthese acclimatiseert aan de verhoogde lichtintensiteit. Het laat zien dat het mogelijk is om de fysiologische en genetische complexiteit van fotosynthese te simplificeren wat leidt tot het identificeren van de genen onderliggende de geassocieerde genetische loci. Dit is bevestigd voor het *YELLOW SEEDLING 1 (YS1)* gen, een gen wat codeert voor een Pentatrico-Peptide-Repeat (PPR) eiwit betrokken bij het aanpassen van het RNA afkomstig van genen gecodeerd op het chloroplast DNA die essentieel zijn voor het functioneren van fotosysteem I en II. Genetische variatie voor iedere eigenschap kan voorkomen op het gebied van gen expressie of op het gebied van functionele eigenschappen van het gecodeerde eiwit. In hoofdstuk 4 wordt de gen expressie regulatie bestudeerd van drie *Arabidopsis* accessies met contrasterende reactievermogens betreffende fotosynthese

efficiëntie op verhoogde lichtintensiteit. De verschillen in reactievermogen betreffende fotosynthese efficiëntie worden geassocieerd met verschillen in activatie van genen betrokken bij reactie op hitte, als wel met verschillen in het aanwezig zijn van een gen activatie reactieroute leidende tot het her-modelleren van membraan lipiden, wat wordt gesuggereerd belangrijk te zijn voor het behouden van gebalanceerde cellulaire fosfaat concentraties. Hoofdstuk 5 bevestigt het belang van het behouden van gebalanceerde cellulaire fosfaat concentraties voor de reactie van fotosynthese efficiëntie op verhoogde lichtintensiteit. Het beschrijft hoe een genoom-wijde associatie studie in natuurlijke accessies en een gen karteringsstudie in genetisch uitsplitsende nakomelingen uit een kruising tussen twee accessies elkaar aanvullen in het onthullen van een genetische epistatische interactie tussen het gen *PHOSPHATIDIC ACID PHOSPHOHYDROLASE 2 (PAH2)*, een gen betrokken bij fosfaat metabolisme) en het gen *ASPARAGINE SYNTHETASE 2 (ASN2)*, een gen betrokken bij nitraat metabolisme), beide handelend in het vrijmaken van orthofosfaat in de chloroplast. In conclusie draagt dit proefschrift bij aan nieuwe inzichten in de mogelijke fysiologische en moleculaire routes voor de reactie van fotosynthese efficiëntie op verhoogde lichtintensiteit.

Acknowledgement / Dankwoord

Als eerste wil ik mijn co-promoter Mark Aarts bedanken voor het aanbieden van dit zeer uitdagende promotie onderzoek. Daarnaast ook bedankt voor alle goede adviezen en de begeleiding bij de uitvoering van de experimenten en het opschrijven van de resultaten.

I would like to thank my co-promoter Jeremy Harbinson for giving me the chance to do this PhD research under his supervision. Thank you for all your advice and guidance throughout the process.

Bedankt aan mijn promotor Maarten Koornneef voor alle adviezen die je mij gegeven hebt betreffende het doen van genetisch onderzoek.

I would like to thank the whole research group of Genetics for being such a welcoming and inspiring group of people. I have always enjoyed talking to all of you and hearing about the different research you were doing.

Although my desk was in the research group of Genetics, I was also part of the research group of Horticulture & Product Physiology (HPP). Although I was not around much in the department, I would like to thank the whole research group of HPP as well. Many of you gave me inspiration especially during the research seminars on Monday afternoons.

Bedankt aan de mensen van Unifarm voor het zorgen voor mijn planten in de klimaatcellen en in de kassen.

Thanks to Aina Prinzenberg for advising me and always helping me in the experiments and most of all for becoming my friend during my PhD time. Thanks for being my paranymph!

Bedankt aan René Boesten voor het zijn van de beste MSc student die ik mij kon wensen en voor het afmaken van de laatste experimenten toen ik het lab al had verlaten om in Düsseldorf te gaan werken. Bedankt ook dat je mijn paranymph wil zijn!

Graag wil ik ook mijn ouders bedanken voor de onvoorwaardelijke steun die zij mij bieden. Dankjewel dat jullie zijn wie jullie zijn en dat ik mag zijn wie ik ben.

Meeste dank gaat naar mijn vriend en geliefde Jan Knippenbergh. Dankjewel dat je er altijd voor mij bent en dat je zo goed kunt luisteren. Dankjewel ook dat je vier jaar lang werkdagen hebt gedraaid van meer dan 9 uur per dag totdat ik jou weer kwam ophalen in Boxmeer, zonder daar ooit over te klagen. Zelfs niet als ik weer eens in de file stond en chagrijnig bij jou aankwam. Jij bent echt een topper, en ik hoop dat we nog heel lang gelukkig samen mogen zijn.

Curriculum Vitae

Roxanne van Rooijen was born on March 31st 1987 in Venlo, the Netherlands. In 2005 she decided to study Biology at the Radboud University in Nijmegen, where she completed her research Master of Science in 2010 and an extra educational master in 2011. During her research master she completed a thesis in the laboratory of Plant Genetics of Radboud University under the supervision of Dr. Janny Peters and a research internship in Nunhems Netherlands (now Bayer Crop Science) in the laboratory of Seed Physiology under the supervision of Dr. Ruud Nabben. After that in 2011 she started her PhD research at Wageningen University under the supervision of Prof. Dr. Maarten Koornneef, Dr. Mark G.M. Aarts, and Dr. Jeremy Harbinson, of which the result is lying in front of you. When her PhD-contract finished in 2015, she started a Postdoc position at Heinrich-Heine Universität in Düsseldorf in the laboratory of Developmental and Molecular Plant Biology under supervision of Prof. Dr. Peter Westhoff, where she currently works.

Publications

van Rooijen R, Aarts MGM, Harbinson J (2015) Natural genetic variation for acclimation of photosynthetic light use efficiency to growth irradiance in Arabidopsis. *Plant Physiology* **167**: 1412-1429.

Van Rooijen R, Boesten R, Kruijer W, van Eeuwijk FA, Harbinson J., Aarts MGM (*in preparation*) A regulator in anterograde signalling underlies natural variation for plant photosynthesis

Education Statement of the Graduate School

Experimental Plant Sciences

Issued to: Roxanne van Rooijen
Date: 5 July 2016
Group: Laboratory of Genetics
University: Wageningen University & Research

| 1) Start-up phase | <u>date</u> |
|---|--------------|
| <ul style="list-style-type: none"> ▶ First presentation of your project Genetic variation in Arabidopsis thaliana of photosynthesis parameters in response to abiotic stress | Sep 13, 2011 |
| <ul style="list-style-type: none"> ▶ Writing or rewriting a project proposal Genetic variation in Arabidopsis thaliana of photosynthesis parameters in response to abiotic stress | 2012 |
| <ul style="list-style-type: none"> ▶ Writing a review or book chapter ▶ MSc courses ▶ Laboratory use of isotopes | |

*Subtotal Start-up Phase 7.5 credits**

| 2) Scientific Exposure | <u>date</u> |
|---|------------------------------------|
| <ul style="list-style-type: none"> ▶ EPS PhD student days 6th European Plant Science Retreat for PhD students in Experimental Plant Sciences, Amsterdam | Jul 03, 2014 Jan 29-30, 2015 |

Subtotal Personal Development 3.0 credits*

| | |
|---------------------------------------|-------------|
| TOTAL NUMBER OF CREDIT POINTS* | 46,4 |
|---------------------------------------|-------------|

Herewith the Graduate School declares that the PhD candidate has complied with the educational requirements set by the Educational Committee of EPS which comprises of a minimum total of 30 ECTS credits

* A credit represents a normative study load of 28 hours of study.
