Wageningen, The Statutory Research Tasks Unit for Nature and the Environment (WOT Natuur & Milieu). WOT-technical report 53. 164 p; 21 Tab.; 1 Fig.; 108 Ref.; 12 Annexes.

The National Emission Model for Agriculture (NEMA) is used to calculate emissions to air from agricultural activities in the Netherlands on a national scale. Emissions of ammonia (NH<sub>3</sub>) and other N-compounds (NO<sub>x</sub> and N<sub>2</sub>O) from animal housing, manure storage, manure application and grazing are assessed using a Total Ammoniacal Nitrogen (TAN) flow model. Furthermore, emissions from application of inorganic N-fertilizer, compost and sewage sludge, cultivation of organic soils, crop residues, and ripening of crops are calculated. NEMA is also used to estimate emissions of methane (CH<sub>4</sub>) from enteric fermentation and manure management, particulate matter (PM) from manure management and agricultural soils, and carbon dioxide (CO<sub>2</sub>) from liming. Emissions are calculated in accordance with international guidance criteria and reported in an annual Informative Inventory Report (IIR; for air pollutants) and National Inventory Report (NIR; for greenhouse gases). This methodology report describes the outline and backgrounds of the emission calculations with NEMA.

# Preface

This report describes the methodologies for estimating emissions to air from agricultural activities in the Netherlands over the 1990-2013 period, as reported in the Informative Inventory Report (IIR; air pollutants) and National Inventory Report (NIR; greenhouse gases) of 2015. An overview of basic principles and results, is also available in the Dutch language (Van Bruggen *et al.*, 2015). The underlying report is an update of the methodology for ammonia emissions from Velthof *et al.* (2009), and replaces the protocols that previously accompanied the annual greenhouse gas reporting.

Calculations are performed with the National Emission Model for Agriculture (NEMA). Various institutes contribute to the annual calculations and maintenance of the model. The authors wish to thank the many colleagues at Statistics Netherlands, the Wageningen UR groups involved (Alterra, LEI, Livestock Research and Plant Sciences Group), PBL Netherlands Environmental Assessment Agency and RIVM for their contributions and support. Peter Zijlema and Harry Vreuls from the Netherlands Enterprise Agency (RVO.nl) provided useful comments on draft versions of the report.

# Summary

The National Emission Model for Agriculture (NEMA) is used to estimate emissions to air from agricultural activities in the Netherlands. Calculations include the emission of ammonia (NH<sub>3</sub>), nitrogen oxides (NO<sub>x</sub>), nitrous oxide (N<sub>2</sub>O), methane (CH<sub>4</sub>), particulate matter (PM<sub>10</sub>, PM<sub>2.5</sub>) and carbon dioxide (CO<sub>2</sub>). These emissions originate from various processes within the agricultural production chain, grouped in the Common Reporting Format (CRF; greenhouse gases) and Nomenclature For Reporting (NFR; air pollutants) main categories 3A Enteric fermentation, 3B Manure management, 3D Agricultural soils and 3G Liming.

## Enteric fermentation

During the digestion of feed, ruminal and/or intestinal fermentation processes take place. Especially in cattle, considerable amounts of CH<sub>4</sub> are formed. In accordance to the key source analysis, a country-specific (IPCC Tier 3) method is used for dairy cattle which models the enteric fermentation processes. For other cattle categories, emissions are calculated from the feed rations on a yearly basis, using an IPCC Tier 2 approach. The emissions from smaller ruminants and intestinal fermentation by monogastric animals, are calculated with IPCC 2006 default emission factors per head (Tier 1).

## Manure management

This category includes emissions from manure stored inside animal houses, and in outside manure storage facilities.

CH<sub>4</sub> emission results from fermentation of organic matter in stored livestock manure. The rate of emission depends on the chemical composition of the manure and on environmental factors like temperature and the availability of oxygen. Cattle, pigs and poultry are considered key sources, and are therefore assessed using an IPCC Tier 2 approach. The excretion of volatile solids is calculated from rations fed, and multiplied by the maximum methane production potential (B<sub>0</sub>) and methane conversion factor (MCF). A distinction is made between liquid and solid manure, and manure excreted on pasture land. Emissions from other animal categories, are calculated using the IPCC 2006 defaults (Tier 1).

NH<sub>3</sub> is produced from urinary nitrogen (N) and mineralized organic N in the faeces, the sum of which is called TAN (Total Ammoniacal Nitrogen). After bacterial conversion to ammonium gaseous NH<sub>3</sub> emits to the air, depending on physical and chemical conditions. TAN in manure is derived from the feed composition on a yearly basis. The NH<sub>3</sub> emission is calculated using NH<sub>3</sub>-N emission factors expressed as % of TAN. These emission factors are directly or indirectly derived from measurements of NH<sub>3</sub> emissions from animal houses, and expressed relative to the respective TAN-excretions. Separate calculations are performed for NH<sub>3</sub> emissions from manure storages outside the animal housing. Because N-emissions are calculated using the TAN-flow principle, the amount of TAN in storage is corrected for all N losses taking place in the housing system.

Emissions of N as NO<sub>x</sub> and N<sub>2</sub>O are also part of the TAN flow and originate from (de-)nitrification in manure during storage in animal housings and in outside storage facilities. The NO<sub>x</sub> and N<sub>2</sub>O emissions are considered to be of equal size in terms of amounts N lost, and based on the IPCC default emission factors for N<sub>2</sub>O. These emissions are converted into % of TAN for use in the TAN flow model.

Particulate matter (PM<sub>10</sub> and PM<sub>2.5</sub>) emissions from manure management mainly depend on the housing systems. Information on housing systems used in practice is derived from the Agricultural Census, and elaborated further by provincial records on environmental permits. Emission factors have been established by, or are deduced from measurements.

## Agricultural soils

As part of the TAN flow, manure N available for application is calculated by subtracting N losses from animal houses and outside manure storages from the total N excretion by livestock. Besides emissions as NH<sub>3</sub>-N, N<sub>2</sub>O-N and NO<sub>x</sub>-N, these losses include N<sub>2</sub>-N (dinitrogen-N), the use of manure N outside agriculture and (net) export of manure N. The resulting application of livestock manure N is then divided over grassland and cropland (cropped and uncropped), with a differentiation between manure application techniques and their respective NH<sub>3</sub> emission factors. For grazed grasslands, NH<sub>3</sub> emission is calculated based on TAN excretion on pasture land and an emission factor depending on the N content of the ration. The NH<sub>3</sub> emissions from application of inorganic N-fertilizer, sewage sludge, compost, and crop residues left on the field are calculated using country-specific emission factors for these sources. For crop ripening a fixed estimate is used, given the large uncertainty associated with this emission source.

Emissions of NO<sub>x</sub> and N<sub>2</sub>O occur when N is applied to agricultural soils. For N<sub>2</sub>O a distinction is made between above-ground and low-ammonia emission application, as incorporation of livestock manure into the soil increases N<sub>2</sub>O emission. The emission factors are country-specific (Tier 2), as well as those for inorganic N-fertilizer, sewage sludge, compost, pasture manure, crop residues and the cultivation of organic soils. Emissions of NO<sub>x</sub> are calculated using the EMEP default emission factor for N supply to soil.

Particulate matter (PM) is emitted during the storage, handling and transport of agricultural products, the cultivation of agricultural soils and crop harvesting. A Tier 2 approach is used for PM<sub>10</sub> and PM<sub>2.5</sub> emissions from the tillage of crops. Other sources of PM emissions (concentrates, inorganic fertilizers and pesticide use) have fixed estimates.

## Liming

Application of lime to reduce soil acidity results in CO<sub>2</sub> emissions, because of decomposition of carbonate. Emissions of CO<sub>2</sub> from lime are calculated from yearly statistics and the IPCC default emission factors (Tier 1).

## Overview of methods and emission factors used

For the reporting of air pollutants within the NFR format, the level of methods and emission factors used by NEMA are summarized in Table S.1.

Table S.1

*Methods and emission factors (EF) used in NEMA for air pollutants, towards level as distinguished by the 2013 EMEP Guidebook*

---

# 1 Introduction

In 2013, the agricultural sector was responsible for more than 85% of total ammonia (NH<sub>3</sub>) emissions in the Netherlands. Agriculture also is a significant contributor towards the emissions of nitrogen oxides (NO<sub>x</sub>). Deposition of NH<sub>3</sub> and NO<sub>x</sub> can lead to adverse effects, in the form of eutrophication and acidification. For emissions of particulate matter agricultural activities form a considerable source as well, especially in the coarse fraction of up to 10 µm in size (PM<sub>10</sub>). Particulate matter can cause detrimental health effects, and forms an uncertain factor in climate change.

With regards to the greenhouse gasses methane (CH<sub>4</sub>) and nitrous oxide (N<sub>2</sub>O), agriculture is the largest contributing source towards national total emissions. Combined and expressed as carbon dioxide equivalents (CO<sub>2</sub>-eq), they amount to about 10% of Dutch greenhouse gas emissions. Stationary combustion (mainly by heating in horticulture) and use of mobile equipment are not included, because these are accounted for in the Energy sector. The only CO<sub>2</sub> emissions reported in the sector of Agriculture originate from calcareous fertilizers (liming).

## 1.1 Reporting requirements and institutional arrangements

Under the Kyoto Protocol, the Netherlands is required to set up and maintain a national system to monitor its greenhouse gas emissions. One of the elements of this system is a transparent and verifiable description of the methods and processes used in this monitoring system. These methods must meet international guideline criteria, which are defined by the United Nations (UN) and the European Union (EU).

The Netherlands also reports emissions of other air pollutants. These are used to check if the Netherlands meets the National Emission Ceilings (NEC) and, as a party to the Convention on Long Range Transboundary Air Pollution (CLRTAP), the Gothenburg Protocol. Here too the methods must meet international guideline criteria, which are defined by the European Monitoring and Evaluation Programme (EMEP) of the European Environment Agency (EEA).

The Pollutant Release and Transfer Register (PRTR, or 'EmissieRegistratie' (ER) in Dutch) collects and formally establishes the yearly emissions of pollutants to air, water and soil. The PRTR is a collaborative group that includes amongst others the institutions: Statistics Netherlands (CBS), Wageningen University & Research Centre (Wageningen UR), the National Institute for Public Health and the Environment (RIVM) and Netherlands Environmental Assessment Agency (PBL). It is coordinated by RIVM under supervision of Netherlands Enterprise Agency (RVO), acting as the National Inventory Entity (NIE) for greenhouse gas reporting. The Ministry of Economic Affairs (EZ) and the Ministry of Infrastructure and Environment (IenM) commission the PRTR.

Within the PRTR several teams work on respective sectors as defined by the guideline criteria, including the task force Agriculture and Land Use. Emissions from Land Use, Land Use Change and Forestry (LULUCF) form a separate sector and therefore are not discussed here. This report deals with emissions to air originating from agricultural activities, for which the National Emission Model for Agriculture (NEMA) of the independent Dutch Scientific Committee of the Manure Act (CDM) is used. The model NEMA was developed in 2009 for NH<sub>3</sub> (Velthof *et al.*, 2009), and since then calculations for emissions of other compounds have been included (Van Bruggen *et al.*, 2014). The current report gives an overview of the methods applied in NEMA to estimate emissions of CH<sub>4</sub>, NH<sub>3</sub>, N<sub>2</sub>O, NO<sub>x</sub>, PM<sub>10</sub>, PM<sub>2.5</sub> and CO<sub>2</sub> from the agricultural sector.

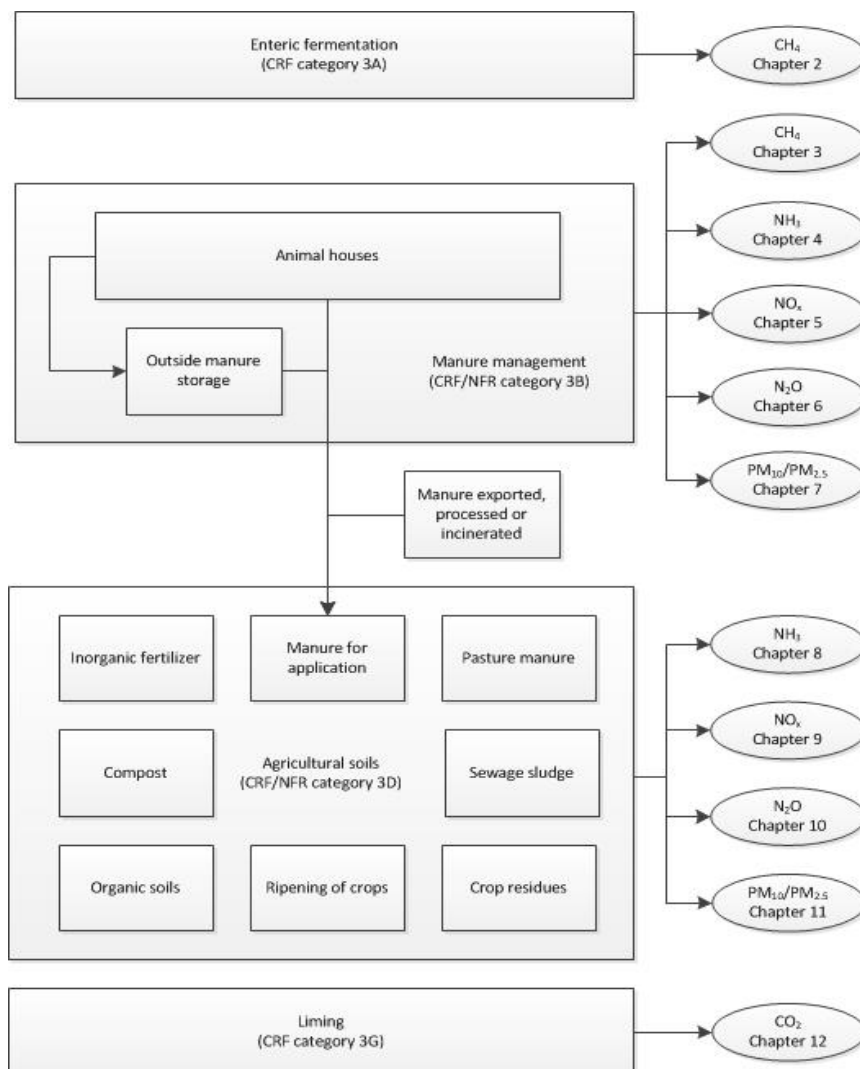

Emission data are available through the website [www.emissieregistratie.nl](http://www.emissieregistratie.nl) and in yearly reports on greenhouse gas emissions (National Inventory Report, NIR) and other pollutants (Informative Inventory Report, IIR). Data from the PRTR are also used for the evaluation of national environmental

policy and in many other environmental reports. For this reason, also yearly reports in Dutch are being published, with updated NEMA results.

## 1.2 Outline of the report

The following chapters describe the scope and definition, calculation method, emission factors, activity data and uncertainty and quality, for each combination of compound and source category distinguished. The categorization of the 2006 Intergovernmental Panel on Climate Change (IPCC) Guidelines and the EMEP Guidebook 2013 is being followed here. For reporting the Common Reporting Format (CRF, to accompany the NIR) and the Nomenclature For Reporting (NFR, accompanying the IIR) are used. Emissions from agriculture occur in the sectors 3A Enteric fermentation, 3B Manure management, 3D Agricultural soils and 3G Liming. Because of climatological conditions, activities related to sectors 3C Rice cultivation and 3E Prescribed burning of savannahs do not occur in the Netherlands. Also no emissions from sector 3F Field burning of agricultural residues take place, as this is prohibited by law.

Figure 1.1 presents an overview of processes and emissions, indicating the chapters in which they are discussed in detail.

**Figure 1.1** Processes and emissions in agriculture with their allocation to CRF and NFR reporting categories

By arranging chapters in a consecutive manner, starting at the animal level and then continuing to manure management (animal housing and outside manure storage), agricultural soils and liming the reader can get a full overview of emission calculations. Repetition of information was kept to a

---

minimum, but as chapters are also intended to be read independently, some repetition could not be avoided. This also means that readers interested in given compound(s) should be able to skip the other chapters.

This report only briefly addresses the factors that influence the processes underlying the emissions. For a thorough description, reference is made to reports (Oenema *et al.*, 2000; Velthof *et al.*, 2009) and other publications or theses (Aarnink, 1997; Bannink, 2007; Bussink, 1996; Groenestein, 2006; Groot Koerkamp, 1998; Huijsmans, 2003; Monteny, 2001; Oenema *et al.*, 2008; Tamminga *et al.*, 2007 and Velthof, 1997).

---

## 2 CH<sub>4</sub> emissions from enteric fermentation (CRF sector 3A)

### 2.1 Scope and definition

This chapter describes the methods and working processes used to determine the emission of methane (CH<sub>4</sub>) from ruminal and intestinal (enteric) fermentation. In the Common Reporting Format (CRF) the following source categories are distinguished:

- 3A1a Mature dairy cattle (ruminal and intestinal fermentation)
- 3A1b Other mature cattle (ruminal and intestinal fermentation)
- 3A1c Growing cattle (ruminal and intestinal fermentation)
- 3A2 Sheep (ruminal and intestinal fermentation)
- 3A3 Swine (intestinal fermentation only)
- 3A4 Other livestock
  - d) Goats (ruminal and intestinal fermentation)
  - e) Horses (intestinal fermentation only)
  - f) Mules and asses (intestinal fermentation only)
  - h) Other (intestinal fermentation only)

The categories 3A4a Buffalo, 3A4b Camels and 3A4c Deer are reported in the CRF as Not Occurring (NO), since these are not kept commercially in the Netherlands. In category 3A4g Poultry emissions are reported as Not Estimated (NE), since the anatomy of the gastro-intestinal tract of poultry (i.e. high passage rate of feed) and the composition of poultry feed (relatively high energy value) result in a negligible contribution of fermentation processes to feed digestion. The 2006 IPCC Guidelines do not provide a default emission factor for poultry either. Under category 3A4h Other, emissions of rabbits and fur-bearing animals are being reported.

The feed consumed by an animal is digested in the gastro-intestinal tract, to provide the energy and nutrients needed for maintenance and production. Part of the (nearly anaerobic) gastro-intestinal tract accommodates a particularly large microbial population, fermenting the feed in which methane is formed as a by-product. In monogastric animals (pigs, horses and mules and asses) this only involves the large intestine and therefore CH<sub>4</sub> production remains relatively low. The gastro-intestinal tract of polygastric animals (cattle, sheep and goats) is specialized to digest fibrous material, especially in the rumen. With intensive microbial fermentation taking place, the rumen gives rise to a considerably larger CH<sub>4</sub> production in ruminants than in monogastric animals.

In addition to the microbial matter synthesized through fermentation of organic matter, volatile fatty acids and hydrogen gas are produced. Just a small fraction of the hydrogen gas is utilized with microbial growth, or with the production of propionic acid and branched chain volatile fatty acids. The surplus of hydrogen is released into the rumen environment, either in rumen fluid or in the gaseous head space. Together with carbon dioxide, which is available in excess in the rumen, the released hydrogen gas is almost completely converted into CH<sub>4</sub> and water by methanogens. Under Dutch feeding conditions of cattle less than 0.5% of hydrogen production was observed to be exhaled, with the remainder exhaled as CH<sub>4</sub> (Van Zijderveld *et al.*, 2011). This fairly complete conversion of hydrogen into CH<sub>4</sub> keeps the partial gas pressure of hydrogen in the rumen environment very low. As a relatively small increase of the partial gas pressure could have a detrimental effect on the fermentative degradation of feed in the rumen as a result of the inhibition of microbial activity (fibre degradation in particular), this is highly functional. Almost all CH<sub>4</sub> (99%) leaves the ruminant via the mouth, via respiration (via blood to the lungs) and by frequent eructations of rumen gases and rumination.

The amount of CH<sub>4</sub> produced by ruminants depends on the amount of feed consumed by the animal and the characteristics and composition of this feed (Veen, 2000; Smink *et al.*, 2003; Tamminga *et al.*, 2007). The amount of feed ingested strongly determines the amount of organic matter fermented,

and with this, the amount of hydrogen gas converted into CH<sub>4</sub>. The feed characteristics (degradability, rate of degradation, outflow to the intestine) determine which fraction of individual feed components ferments in the rumen and which fraction escapes rumen fermentation and flows out to the small intestine (Dijkstra *et al.*, 1992). The chemical composition of the fermented part of the feed determines the amount and type of volatile fatty acids produced (Bannink *et al.*, 2008; Kebreab *et al.*, 2009), and is thereby an important determinant of the surplus of hydrogen in the rumen that becomes converted into CH<sub>4</sub> (Mills *et al.*, 2001; Ellis *et al.*, 2008; Bannink *et al.*, 2011).

In conclusion, the amount and type of ingested feed determines the emission factor (EF) for CH<sub>4</sub> (i.e. the amount of CH<sub>4</sub> in kg CH<sub>4</sub>/year that is produced by an animal), partly through its effect on the so-called methane conversion factor (Y<sub>m</sub>, i.e. the fraction of gross energy in ingested feed that is converted into CH<sub>4</sub>).

## 2.2 Calculation method

The emission of CH<sub>4</sub> as a result of ruminal and intestinal fermentation in cattle is calculated by multiplying the number of animals per livestock category by a country-specific emission factor for that livestock category. For the other livestock categories, default EFs are used according to the IPCC 2006 Guidelines. The total emission of CH<sub>4</sub> of all animals is calculated by summing the emissions per livestock category.

$$\text{CH}_4 \text{ emissions } 3A = \sum_i [\text{number of animals in livestock category } (i)] \times \text{EF CH}_4 \text{ } 3A_i \quad (2.1)$$

In which

CH<sub>4</sub> emissions 3A : Methane emission (kg CH<sub>4</sub>/year) for all defined livestock categories (i) within the CFR source category 3A enteric fermentation  
 EF CH<sub>4</sub> 3A<sub>i</sub> : Emission factor (kg CH<sub>4</sub>/animal/year) for enteric fermentation of livestock category (i)

### Comparison to IPCC methodology

For all livestock categories, excluding cattle, Tier 1 default IPCC emission factors are applied. For cattle, excluding mature dairy cattle, the Tier 2 approach is applied, with intake of gross energy being calculated according to a country-specific method. In this method the EF is calculated using the Y<sub>m</sub> and the gross energy (GE; MJ/kg dry matter) intake from feed (GE<sub>i</sub>; MJ/animal/day). The default IPCC value of 0.065 is used as Y<sub>m</sub>, except for white veal calves since these are fed milk products and therefore do not show full rumen development (Gerrits *et al.*, 2014).

For mature dairy cattle, a country-specific Tier 3 approach is applied by using a dynamic simulation model which describes the mechanisms of the fermentation processes in the gastrointestinal tract (Bannink *et al.*, 2011). The model predicts the consequences of nutrition on microbial fermentation and the accompanying production of CH<sub>4</sub> in the rumen and the large intestine. The simulation model predicts GE<sub>i</sub> and the production of CH<sub>4</sub> in the rumen and large intestine from feed intake and dietary characteristics (dry matter intake, chemical composition, rumen degradation characteristics). Subsequently, the model calculates the Y<sub>m</sub> from predicted CH<sub>4</sub> emission and GE<sub>i</sub>. Therefore, the model predicts Y<sub>m</sub> instead of assuming a constant Y<sub>m</sub> value as a model input, as is the case with the Tier 2 approach.

## 2.3 Emission factors

For all livestock categories excluding cattle, a Tier 1 approach is applied with default emission factors as described in the IPCC Guidelines (2006; p. 10.28). Table 2.1 gives an overview of the EFs used.

Table 2.1

Emission factors for all livestock categories, excluding cattle

| Livestock category | EF in kg CH <sub>4</sub> /animal/year |
|--------------------|---------------------------------------|
| Sheep              | 8.00                                  |
| Goats              | 5.00                                  |
| Horses             | 18.00                                 |
| Mules and asses    | 10.00                                 |
| Pigs               | 1.50                                  |

Source: IPCC (2006).

### Cattle excluding mature dairy cattle and white veal calves

Cattle is considered a key source (Coenen *et al.*, 2014) and therefore, for all cattle categories excluding white veal calves and mature dairy cattle, a Tier 2 approach is followed to calculate the country-specific emission factor. The emission factor is expressed by the following equation:

$$EF_{CH_4} = (Y_{mi} \times GE_i) / 55.65 \quad (2.2)$$

In which

$Y_{mi}$  : Methane conversion factor for livestock category (i) (fraction of gross energy intake (GE) that is converted into CH<sub>4</sub>)

$GE_i$  : Gross energy intake (MJ/animal/year) for livestock category (i)

A default value of 0.065 is used for the  $Y_m$  as described in the Guidelines (IPCC, 2006), with the exception of white veal calves. It is assumed that 1 kg CH<sub>4</sub> has a standard energy content of 55.65 MJ (IPCC, 2006).

The  $GE_i$  is calculated according to the following equation:

$$GE_i = DM_i \times 18.45 \quad (2.3)$$

In which

$DM_i$  : Dry matter intake (kg dry matter/animal/year) for livestock category (i)

It is assumed that 1 kg dietary dry matter has a gross energy content of 18.45 MJ/kg dry matter (IPCC, 2006), with the exception of milk products fed to white veal calves (21.00 MJ/kg DM; Gerrits *et al.*, 2014).

### White veal calves

The production of white veal forms a considerable sector in the Netherlands. Rations consist largely or entirely out of milk products, with low associated  $Y_m$  as milk products are not fermented in the rumen. In order to improve animal welfare, over time rations have been supplemented with increasing amounts of concentrates and roughages. As the rumen will still not be fully developed in white veal calves,  $Y_m$  for these ration components was observed to be lower than the default value of 0.065. Specific  $Y_m$  values of 0.003 for milk products and 0.055 for other ration components are assumed, and a GE of 21.00 MJ/kg DM for milk products is used (Gerrits *et al.*, 2014):

$$EF_{CH_4} = (Y_{m,milk\ products} \times GE_{milk\ products} + Y_{m,other\ ration\ components} \times GE_{other\ ration\ components}) / 55.65 \quad (2.4)$$

In which

$EF_{CH_4}$  : Emission factor (kg CH<sub>4</sub>/animal/year) for enteric fermentation of white veal calves

$Y_{m,milk\ products}$  : Methane conversion factor for milk products (fraction of gross energy intake (GE) that is converted into CH<sub>4</sub>)

$GE_{milk\ products}$  : Gross energy intake (MJ/animal/year) with milk products

$Y_{m,other\ ration\ components}$  : Methane conversion factor for other ration components (fraction of gross energy intake (GE) that is converted into CH<sub>4</sub>)

$GE_{other\ ration\ components}$  : Gross energy intake (MJ/animal/year) with other ration components

---

## Mature dairy cattle

For mature dairy cattle a Tier 3 approach is applied to calculate country-specific emission factors, split in the regions North-West and South-East of the Netherlands. Because both regions have different ration compositions, emissions are also different. The most important difference with the Tier 2 approach is that the simulation model predicts the EF from feed intake and dietary characteristics as model inputs, without using the values of  $GE_i$  or  $Y_m$ . Another important difference with the Tier 2 approach is that the simulation model takes into account several dietary characteristics to predict the fermentation processes in the rumen and large intestine, instead of using only the net energy value for milk production and maintenance as a dietary characteristic. A final difference with the Tier 2 approach is that the simulation model calculates  $GE_i$  from dry matter intake and dietary composition instead of adopting a GE value for feed DM. The EF,  $GE_i$  and  $Y_m$  of mature dairy cattle are calculated yearly (Bannink, 2011).

The simulation model describes  $CH_4$  production as a result of microbial fermentation processes in the gastrointestinal tract of mature dairy cattle. The simulation model is developed by Dijkstra *et al.* (1992), Mills *et al.* (2001), and Bannink *et al.* (2005, 2008, 2011) and is described in scientific (peer-reviewed) journals. Mills *et al.* (2001) added a representation of  $CH_4$  production to the model of rumen fermentation processes developed by Dijkstra *et al.* (1992), including a representation of the fermentation processes in the large intestine. This model extension calculates the production of volatile fatty acids and hydrogen (the latter converted into  $CH_4$ ) according to Bannink *et al.* (2006). More recently, an improved representation was included of the production of volatile fatty acids and hydrogen by making this dependent on the acidity of rumen contents (Bannink *et al.*, 2005, 2008, 2011). This version of the simulation model is applied since 2005 as a Tier 3 approach to calculate  $CH_4$  emissions in mature dairy cattle. Although the model can also be used for other cattle categories, it is currently not applied for this purpose because of budget constraints and lack of model evaluation results for other categories.

Based on predicted values of EF and  $GE_i$  the simulation model calculates an  $Y_m$  value. The  $Y_m$  is hence not part of the assumptions made in the model representation but is a predicted outcome of the model in the same unit as used for  $Y_m$  with other categories. From the predicted values of the emission factor (EF) and the Gross Energy intake ( $GE_i$ ) per year, the  $Y_m$  is calculated as follows:

$$Y_m = EF \times 55.65 / (GE \times 365) \quad (2.5)$$

In which

- $Y_m$  : Methane conversion factor (fraction of gross energy intake converted into  $CH_4$ )
- EF : Emission factor (kg  $CH_4$ /animal/year) calculated with the simulation model
- GE : Gross energy intake (MJ/animal/day) calculated with the simulation model

It is assumed that 1 kg  $CH_4$  has a standard energy content of 55.65 MJ (IPCC, 2006), and the factor 365 was used to calculate  $GE_i$  on a yearly basis.

Should the results from the simulation model not be available in a particular year, a secondary (simplified) approach is used to calculate the emission factor, where the  $Y_m$  and  $GE_i/DM_i$  from the three preceding years will be used (as a back-up option). The following equation is then used to calculate the emission factor:

$$EF = (DM_i \times 365 \times GE / DM_i (\text{gross energy content in dry matter; average of year } n-1 \text{ to year } n-3) \times Y_m (\text{average year } n-1 \text{ to year } n-3) ) / 55.65 \quad (2.6)$$

In which

- EF : Emission factor (kg  $CH_4$ /animal/year)
- $DM_i$  : Dry matter intake (kg dry matter/animal/day)
- GE : Gross energy intake (MJ/animal/day)
- $Y_m$  : Methane conversion factor (fraction of gross energy intake (GE) converted into  $CH_4$ )

---

It is assumed that 1 kg CH<sub>4</sub> has a standard energy content of 55.65 MJ (IPCC, 2006), and the factor 365 is used to calculate DM<sub>i</sub> on a yearly basis.

The emission factor is calculated more accurately with equation 2.6 since estimates are based on dietary characteristics of three consecutive previous years instead of using characteristics of only one single year. The Y<sub>m</sub> depends on all input data to the simulation model: 1) the level of feed intake, 2) the chemical composition of ingested feed, and 3) the degradation characteristics in the rumen. The origin of this data is described in the next section.

## 2.4 Activity data

This section provides a more detailed description of the data required as well as the origin of these data.

### **Animal numbers**

Annex 1 presents an overview of the animal (sub-)categories being distinguished in the Agricultural Census. This categorization is also used within the NEMA calculations, and results are then grouped towards reporting categories as indicated.

Since the IPCC Tier 1 EFs are averages for both sexes and over all age groups, they are to be multiplied by the total number of animals (i.e. including young and male animals) within each livestock category. Different than in emissions of N containing compounds, where excretion by young and male animals is accounted for in the excretion of mother animals, for CH<sub>4</sub> from enteric fermentation total number of sheep, goats and pigs are used in the calculations.

PVE (2005) estimated the number of privately owned horses and ponies in the Netherlands to be 300,000. In contrast to large-scale pollutants, the Netherlands has chosen not to report greenhouse gas emissions under the 'Other' category, therefore privately owned horses and ponies are added to the horses and ponies in the Agricultural Census.

### **Feed intake and ration of cattle, excluding mature dairy cattle**

Dry matter intake (DM<sub>i</sub>; kg dry matter/animal/day) is derived from calculations by the Dutch Working group on Uniformity of calculations of Manure and mineral data (WUM). The intake of various components in the ration (grass silage, maize silage, standard concentrates, protein-rich concentrates and wet by-products) is calculated yearly per cattle category based on national statistics on the amounts of these products that have been traded or produced. These statistics on dietary components cover part of the total energy requirement that is calculated yearly according to a country-specific method for the various cattle categories. Subsequently, it is assumed that the remainder of the energy requirement for the recorded production level is covered by the intake of grass from grazing. From 1990 onwards, the WUM calculates the DM intake and ration yearly, which is also input for the method used to calculate manure production and mineral excretion by farm animals (Van Bruggen, 2003 through 2014). The first release appeared in 1994 (WUM, 1994) and a revised calculation of the rations (from 1990 to 2008) appeared in 2009 (CBS, 2009). The DM intake of cattle, excluding mature dairy cattle, is given in the report written by Smink (2005) and in Van Bruggen *et al.* (2015).

### **Feed intake of mature dairy cattle**

Important input data for the simulation model are:

1. Feed intake levels, DM<sub>i</sub>, as calculated by WUM (CBS, 2009) for the regions North-West and South-East, according to the same method as described above for cattle, excluding mature dairy cattle.
2. The chemical composition of DM in the various dietary components (grass herbage, grass silage, maize silage, standard concentrates, protein-rich concentrates and wet by-products). A distinction is made between soluble carbohydrates (including sugars), starch, cell walls (hemi-cellulose, cellulose, lignin), crude protein (including a distinction of the ammonia fraction), crude fat and crude ash. Data on the composition is derived from information from the laboratory Blgg in Wageningen ([www.blgg.agroxpertus.nl](http://www.blgg.agroxpertus.nl)), which analyses roughages, and from producers of compound feed. The data used have been previously described by Smink *et al.* (2005). With a

recent revision of the WUM rations from 1990 to 2008 by CBS (CBS, 2009) new calculations have been conducted and data of chemical composition is attached to the report of Bannink (2011). Part of the ensiled roughage is not fed to dairy cattle in the same year as the roughage analysis was performed. Therefore, in the annual ration calculations a correction on ensiled roughage is made (CBS, 2009).

3. Rumen intrinsic degradation characteristics of starch, crude protein and fibre. The report by Bannink (2011) also gives the assumptions on these degradation characteristics (soluble/washable fraction, fraction that is potentially degradable, undegradable fraction and the fractional degradation rate of the fraction that is potentially degradable).

Data varies with annual changes in the proportion of individual dietary components (grass herbage, grass silage, maize silage, standard concentrates, protein-rich concentrates, wet by-products) and with changes in chemical composition and intrinsic degradation characteristics of these chemical fractions. The fractional passage rate of fermentable matter and acidity of contents in the rumen and the large intestine are also important model parameters that have a considerable influence on predicted CH<sub>4</sub> production. However, this concerns internal model parameters which do not need to be given as an input to the model. Within the current method the simulation model predicts the fractional passage rate as a function of DM<sub>i</sub>, and acidity as a function of predicted concentration of volatile fatty acids according to Mills *et al.* (2001). Sensitivity of model predictions for the parameter values and the effect on uncertainty have been described (Bannink, 2011).

## 2.5 Uncertainty and quality

A Tier 1 uncertainty analysis is implemented every year before the NIR is submitted by the ER, based on the greenhouse gas inventory and in compliance with IPCC Guidelines. The assumptions used and the results thereof are described in an annex to the NIR. In addition to this, where included in the QA/QC-programme for the relevant period, extra analyses are implemented regularly in specific situations, which include any updating of the Tier 2 uncertainty analyses.

The Tier 2 uncertainty assessment was last updated in 2009. This assessment showed that a Tier 1 uncertainty assessment is sufficiently reliable and that Tier 2 uncertainty assessments need only be implemented at periodic intervals of around 5 years, unless a major change in an important source is sufficient to require earlier reassessment.

### Source specific uncertainty

The uncertainty estimate<sub>total</sub> concerns the root of the sum of uncertainty in the data sources used (AD<sub>unc</sub>) in the square and the uncertainty of the emission factor (EF<sub>unc</sub>) in the square. The extent of the total uncertainty is here primarily determined by the greatest AD or EF uncertainty.

$$\text{Uncertainty estimate}_{\text{total}} = \sqrt{(\text{EF}_{\text{unc}}^2 + \text{AD}_{\text{unc}}^2)} \quad (2.7)$$

The uncertainty estimates concerning the data sources (AD) and emission factors (EF) used, and the total uncertainty estimate, are listed in the following Table 2.2.

Table 2.2

*Uncertainty estimates for CH<sub>4</sub> from CRF sector 3A Enteric fermentation*

| IPCC | Category   | AD <sub>unc</sub> | EF <sub>unc</sub> | Uncertainty estimate <sub>total</sub> |
|------|--|-------------------|-------------------|---------------------------------------|
| 3A1a | Emission with ruminal and intestinal fermentation: mature dairy cattle | 5                 | 15                | 16                                    |
| 3A1  | Emission with ruminal and intestinal fermentation: other cattle        | 5                 | 20                | 21                                    |
| 3A3  | Emission with intestinal fermentation: pigs                            | 5                 | 50                | 50                                    |
| 3A   | Emission with intestinal fermentation: other                           | 5                 | 30                | 30                                    |

---

The uncertainty of CH<sub>4</sub> emissions as a result of ruminal and intestinal fermentation is based on expert judgement. Uncertainty in activity data (= animal numbers) is about 5% and uncertainty in the CH<sub>4</sub> EF for other cattle (excluding mature dairy cattle), pigs and other livestock (horses, mules and asses, sheep, goats) is respectively 20, 50 and 30% (Olivier *et al.*, 2009).

Uncertainty of the CH<sub>4</sub> EF for ruminal and intestinal fermentation in mature dairy cattle is based on an analysis of the effect of uncertainty of input data for a simulation model, used as a Tier 3 approach, on predicted EF and Y<sub>m</sub> (Bannink, 2011). Because the model is not applied with other cattle, the lower estimate of uncertainty for mature cattle is not applicable to this category of cattle.

A detailed overview of quality assurance and quality control is given in Annex 12. In this annex also some outlines on the verification of data are presented.

---

# 3 CH<sub>4</sub> emissions from manure management (CRF sector 3B)

## 3.1 Scope and definition

This chapter describes the methodology and working processes for determining CH<sub>4</sub> emissions from manure in animal housings and outside storages, or produced on pasture land during grazing. In the Common Reporting Format (CRF) the following source categories are distinguished:

- 3B1a Mature dairy cattle
- 3B1b Other mature cattle
- 3B1c Growing cattle
- 3B2 Sheep
- 3B3 Swine
- 3B4 Other livestock
  - d) Goats
  - e) Horses
  - f) Mules and asses
  - g) Poultry
  - h) Other

The source categories 3B4a Buffalo, 3B4b Camels and 3B4c Deer are reported as Not Occurring (NO), because these are not kept commercially in the Netherlands. Under category 3B4h Other, rabbits and fur-bearing animals are being reported.

Methane emissions from livestock manure are caused by fermentation of organic matter in an anaerobic environment. It takes some time for methanogenic bacteria to develop and produce methane. This implies that when manure is stored for shorter than a month methane production will remain very low. To what extent organic matter is converted in methane also depends on the (chemical) composition of the manure and environmental factors like temperature. Webb *et al.* (2012) present an overview of key factors affecting methane emission.

Livestock manure can be liquid or solid, depending on the animal category and manure management system (like the use of straw). It is called liquid when it is flowing under gravity and pumpable, solid manure is stackable and can be packed in heaps (RAMIRAN Glossary, 2011). Liquid manure is anaerobic, solid manure, when not packed or compressed, is more aerated, resulting in lower CH<sub>4</sub> emissions.

- Cattle manure can be liquid (slurry) or solid, possibly with a share of urine and faeces excreted during grazing. In general female young stock, dairy and suckling cows are kept on pasture land during the summer months. All dairy cows spend part of the day inside the animal house depending on the applied grazing system, particularly at night and during milking times. With an increase of the number of animals per farm, more animals are kept inside the animal house the whole year round. This implies that also during the summer months all of the manure (and methane) is produced in the animal house.
- Pig manure in the Netherlands is mainly liquid. A minor part is solid, produced by pigs for breeding (sows and boars for service) when bedding material is used (for instance straw).
- Poultry includes laying hens, broilers, ducks and turkeys. Because of the high dry matter content of poultry faeces and the management systems used, currently all poultry manure is considered solid. In earlier years of the time series, battery cage systems producing liquid manure are also taken into consideration.
- Goats in the Netherlands are milking goats, which are kept inside the animal house throughout the year and produce solid manure.
- Sheep are grazing animals and only spend time inside the animal house during the lambing season, where they produce solid manure.

- Horses, mules and asses produce manure in the animal house and during grazing. Solid manure is produced in the period inside the animal house.
- Rabbits and fur-bearing animals (minks, foxes) are kept indoors year-round, and can produce either solid or liquid manure depending on the housing system.

Liquid manure of pigs and cattle is often stored underneath the slatted floors of animal houses in slurry pits, and manure storage facilities outside the animal house. Solid manure is stored in the animal house and stacked outdoors, in most cases with a roof to avoid rainwater. In both cases anaerobic conditions can occur, resulting in the production and emission of CH<sub>4</sub>.

The slurry pit is a so-called accumulation system: there is a constant input of manure and the volume increases until it is removed. The methane emission in such a system increases as the manure temperature rises and the manure is stored for longer periods (Zeeman, 1994). Additionally, when older manure with high methanogenic activity is already present (inoculation) methane emission also increases.

Methane emission from manure excreted during grazing is low, because of the aerobic conditions and fast drying of manure.

## 3.2 Calculation method

The total CH<sub>4</sub> emissions from manure management are calculated by summing the CH<sub>4</sub> emissions for all livestock categories:

$$\text{CH}_4 \text{ emissions } 3B = \sum \text{CH}_4 \text{ emissions from manure excreted by livestock category (i)} \quad (3.1)$$

In which

CH<sub>4</sub> emissions 3B : Methane emission (kg CH<sub>4</sub>/year) from manure for all defined livestock categories (i) within CRF category 3B manure management

Cattle, pigs and poultry are considered to be key-sources (Coenen *et al.*, 2014) and therefore EFs are calculated with a Tier 2 approach. In this approach, distinction is made between liquid manure management systems, solid manure management systems and pasture manure.

$$\text{CH}_4 \text{ emissions in livestock category (i)} = \sum [ \text{number of animals in livestock category (i)} ] \times [ \text{fraction manure management system (j)} ] \times \text{EF CH}_4 \text{ 3B}_{ij} \quad (3.2)$$

In which

EF CH<sub>4</sub> 3B<sub>ij</sub> : Emission factor (kg CH<sub>4</sub>/animal) for the manure management of livestock category (i) and manure management system (j)

With respect to the other livestock categories, default Tier 1 EFs are used (IPCC, 2006).

$$\text{CH}_4 \text{ emissions in livestock category (i)} = [ \text{number of animals in livestock category (i)} ] \times \text{EF CH}_4 \text{ 3B}_i \quad (3.3)$$

In which

EF CH<sub>4</sub> 3B<sub>i</sub> : Emission factor (kg CH<sub>4</sub>/animal) for the manure management of livestock category (i)

## 3.3 Emission factors

For the key livestock categories cattle, pigs and poultry a country-specific emission factor is calculated for each manure management system using the following formula:

$$EF_{CH_4} = VS_i \times B_{oi} \times MCF_{ij} \times \text{methane density} \quad (3.4)$$

In which

|                 |   |
|-----------------|---|
| $VS_i$          | : Volatile solids (kg VS/year) produced by livestock category (i)   |
| $B_{oi}$        | : Maximum methane production potential ( $m^3 CH_4/kg VS$ ) for the manure produced by livestock category (i) |
| $MCF_{ij}$      | : Methane conversion factor for livestock category (i) and manure management system (j)                       |
| Methane density | : $0.67 kg/m^3 CH_4$  |

### Volatile solids (VS)

The amount of volatile solids (VS) excreted is calculated for the key categories cattle, pigs and poultry (Zom and Groenestein, 2015). The amount of volatile solids excreted by livestock depends on the digestibility of the organic matter and protein of the feed components. VS excretion in urine is calculated as the amount of urea ( $CH_4N_2O$ ) or uric acid ( $C_5H_4O_3N_4$ ) from the digestibility of crude protein, which is also used in the calculation of TAN. In faeces VS depends on DM uptake, ash content therein and digestibility of the VS (Zom and Groenestein, 2015).

#### *Maximum methane production potential ( $B_o$ )*

The  $B_o$  depends on the degradability of the organic components in the manure.  $B_o$  is expressed in  $m^3 CH_4/kg VS$  and are 0.25 for cattle manure, and 0.34 for pig and poultry manure (Zeeman, 1994; Zeeman and Gerbens, 2002).

#### *Methane Conversion Factor (MCF)*

The MCF indicates which part of  $B_o$  will actually be converted into methane depending on degradability and environmental conditions. Zeeman and Gerbens (2002) found an MCF of 0.39 for liquid pig and poultry manure stored for six months at a manure temperature of 15 °C, during three months at 20 °C, or for cattle manure stored for 5-6 months at 20 °C.

Information concerning total pig manure storage capacity and the proportion of inside and outside manure storage capacity are taken from studies from Van der Hoek (1994) and CBS (1997 and 2006). Temperatures of manure in inside and outside storage are based on data of De Mol and Hilhorst (2003 and 2004). For cattle, it is assumed that the proportion of inside and outside manure storage capacity (from the early 1990s onwards) is also applicable in following years. The Netherlands uses a country-specific value for cattle manure (MCF = 0.284), based on a manure storage time of six months at a manure temperature of 15 °C (Zeeman, 1994). For cattle, the Netherlands also uses a lower manure temperature for outside storage facilities, and a lower manure temperature during the winter for slurry pits under animal houses.

It is assumed that the total storage capacity for pig manure is six months: four months in the slurry pit and two months in outside storage facilities. Because it is not allowed to apply manure during the winter in the Netherlands, it is assumed that all manure storage facilities are empty on September 1st and that the slurry pit inside the animal house is fully filled, before manure is transferred to the outside storage facilities. Another assumption is that both the slurry pit and the outside storage facilities are empty on March 1st (Van der Hoek and Van Schijndel, 2006). From 1997 onwards, the total storage capacity (under the animal house) for pig manure is six months (obligation related to implementation of Nitrates Directive).

For solid manure and manure on pasture land, the default IPCC MCF values of respectively 0.02 and 0.01 are used. Table 3.1 presents an overview of the MCF values used.

For all other livestock categories, the Tier 1 default emission factors from Table 3.2 are used (IPCC, 2006).

Table 3.1

*MCF values used per animal category*

|                               | 1990-1992 | 1993-1996 | From 1997 on |
|-------------------------------|-----------|-----------|--------------|
| <b>Liquid manure</b>          |           |           |              |
| Cattle, excluding veal calves | 0.17      | 0.17      | 0.17         |
| Veal calves                   | 0.14      | 0.14      | 0.14         |
| Pigs                          | 0.34      | 0.36      | 0.39         |
| Laying hens                   | 0.39      | 0.39      | 0.39         |
| <b>Solid manure</b>           |           |           |              |
| Cattle                        | 0.02      | 0.02      | 0.02         |
| Pigs                          | 0.02      | 0.02      | 0.02         |
| Poultry                       | 0.015     | 0.015     | 0.015        |
| <b>Pasture manure</b>         |           |           |              |
| Cattle                        | 0.01      | 0.01      | 0.01         |

Table 3.2

*Emission factors for all livestock categories (excluding cattle, pigs and poultry)*

| Animal category                       | EF in kg CH <sub>4</sub> /animal/year |
|---------------------------------------|---------------------------------------|
| Sheep                                 | 0.19                                  |
| Goats                                 | 0.13                                  |
| Horses                                | 1.56                                  |
| Mules and asses                       | 0.76                                  |
| Rabbits                               | 0.08                                  |
| Fur-bearing animals (minks and foxes) | 0.68                                  |

Source: IPCC (2006).

## 3.4 Activity data

### Animal numbers

Annex 1 presents an overview of the animal (sub-)categories being distinguished in the Agricultural Census. This categorization is also used within the NEMA calculations, and results are then grouped towards reporting categories as indicated.

Since the IPCC Tier 1 EFs are averages for both sexes and over all age groups, they are to be multiplied by the total number of animals (i.e. including young and male animals) within each livestock category. Different than in emissions of N containing compounds, where excretion by young and male animals is accounted for in the excretion of mother animals, for CH<sub>4</sub> from manure management total number of sheep, goats and rabbits are therefore used in the calculations.

PVE (2005) estimated the Netherlands has 300,000 privately owned horses. This number is added to the result of the Agricultural Census, and resulting emissions are attributed to agriculture. In contrast to large-scale pollutants, the Netherlands has chosen not to report greenhouse gas emissions under the 'Other' category.

### Distribution between the manure management systems

The proportion of liquid and solid manure depends on how manure is managed in the housing systems. Data on these are derived from the Agricultural Census, supplemented by information on environmental permits issued by local authorities. The length of the grazing period in days per year and hours per day indicate the fraction of manure excreted on pasture land. This is indicated by the Dutch Working group on Uniformity of calculations of Manure and mineral data (WUM). According to the IPCC method, liquid manure is divided into two groups: storage in slurry pits lasting less than one month, and storage lasting longer than one month.

## 3.5 Uncertainty and quality

A Tier 1 uncertainty analysis is implemented every year before the NIR is submitted by the ER, based on the greenhouse gas inventory and in compliance with IPCC Guidelines. The assumptions used and the results thereof are described in an annex to the NIR. In addition to this, where included in the QA/QC-programme for the relevant period, extra analyses are implemented regularly in specific situations, which include any updating of the Tier 2 uncertainty analyses.

The Tier 2 uncertainty assessment was last updated in 2009. This assessment showed that a Tier 1 uncertainty assessment is sufficiently reliable and that Tier 2 uncertainty assessments need only be implemented at periodic intervals of around 5 years, unless a major change in an important source is sufficient to require earlier reassessment.

### Source specific uncertainty

The uncertainty estimate<sub>total</sub> concerns the root of the sum of uncertainty in the data sources used ( $AD_{unc}$ ) in the square and the uncertainty of the emission factors ( $EF_{unc}$ ) in the square. The extent of the total uncertainty is here primarily determined by the greatest AD or EF uncertainty.

$$\text{Uncertainty estimate}_{\text{total}} = \sqrt{(AD_{unc}^2 + EF_{unc}^2)} \quad (3.5)$$

The uncertainty estimates concerning the data sources (AD) and emission factors (EF) used, and the total uncertainty estimate, are listed in the following Table 3.3.

Table 3.3

*Uncertainty estimates for CH<sub>4</sub> from CRF sector 3B manure management*

| IPCC | Category                                  | $AD_{unc}$ | $EF_{unc}$ | Uncertainty estimate <sub>total</sub> |
|------|---|------------|------------|---------------------------------------|
| 3B1  | Emissions from manure management: cattle  | 10         | 100        | 100                                   |
| 3B3  | Emissions from manure management: pigs    | 10         | 100        | 100                                   |
| 3B4g | Emissions from manure management: poultry | 10         | 100        | 100                                   |
| 3B   | Emissions from manure management: other   | 10         | 100        | 100                                   |

The uncertainty in the CH<sub>4</sub> emissions from the management of manure from cattle and pigs was estimated to be approximately 100%, annually. The uncertainty in the amount of animal manure (10%) was based on a 5% uncertainty in animal numbers and a 5 to 10% uncertainty in excretion per animal (RIVM, 1999). The resulting uncertainty of 7 to 11% was rounded off to 10%. The uncertainty in the CH<sub>4</sub> emission factors for manure management, based on expert judgements, was estimated to be 100% (Olivier *et al.*, 2009).

A detailed overview of quality assurance and quality control is given in Annex 12. In this annex also some outlines on the verification of data are presented.

---

# 4 NH<sub>3</sub> emissions from manure management (NFR category 3B)

## 4.1 Scope and definition

This chapter describes the methods and working processes for determining NH<sub>3</sub> emissions from manure management, using the following Nomenclature For Reporting (NFR) categories:

- 3B1a Dairy cattle
- 3B1b Non-dairy cattle
- 3B2 Sheep
- 3B3 Swine
- 3B4d Goats
- 3B4e Horses
- 3B4f Mules and asses
- 3B4gi Laying hens
- 3B4gii Broilers
- 3B4h Other animals

Buffalo (3B4a) are reported as Not Occurring (NO), because these are not kept commercially in the Netherlands. Turkeys (3B4giii) and Other poultry (3B4giv; concerns ducks) are included within the category Broilers, and therefore reported as Included Elsewhere (IE).

NH<sub>3</sub> emissions from animal housing and outside manure storage originate mainly from nitrogen excreted in the urine and to a small extent from mineralized organically bound N in faeces. In mammals this nitrogen is excreted as urea (CH<sub>4</sub>N<sub>2</sub>O) and in birds as uric acid (C<sub>5</sub>H<sub>4</sub>O<sub>3</sub>N<sub>4</sub>). Both urea and uric acid are converted by bacterial enzymes (urease and uricase) into ammonium (NH<sub>4</sub><sup>+</sup>). For urea this process generally takes less than 24 hours (Elzing and Monteny, 1997), while uric acid breaks down less quickly (Groot Koerkamp, 1998). At high pH, NH<sub>4</sub><sup>+</sup> is converted to NH<sub>3</sub> which emits in a process affected by physical (air speed, area, temperature) and chemical (NH<sub>4</sub><sup>+</sup> concentration, pH, ion strength) factors.

The sum of the amount of ammonia (NH<sub>3</sub>) and ammonium (NH<sub>4</sub><sup>+</sup>) is called total ammoniacal N (TAN). The N-flow method described in Velthof *et al.* (2009) and in this methodology report calculates the gaseous N emissions based on TAN. This is a change with respect to methodologies used earlier in the Netherlands, which used emission factors based on total N excretion (Oenema *et al.*, 2000; Van der Hoek, 2002). The excretion of TAN is calculated as the sum of excretion of urine N and net mineralized organically bound N in faeces. The net mineralized organically bound N is used since TAN can also be immobilized and become organic N.

There is international consensus about the advantages of a methodology to calculate NH<sub>3</sub> emissions on the basis of TAN instead of total N:

- Gaseous N components are formed from NH<sub>4</sub><sup>+</sup> in the manure and research under controlled conditions shows that the NH<sub>3</sub> emission is better related to the NH<sub>4</sub><sup>+</sup> content than the content of total N in manure (e.g. Velthof *et al.*, 2005).
- A measure that does not change the total amount of N in the manure, but does change the amount of TAN, does affect NH<sub>3</sub> emission as well. With an emission factor based on total N this effect cannot be calculated. Rations do not only have an effect on total N excretion, but also on the share TAN of the excretion (Annexes 2, 3 and 4). The effects of ration composition on NH<sub>3</sub> emission can be quantified better with a methodology based on TAN.
- The emission factor for application of manure is based on TAN (Section 8.3.2). In the former methodology the emission after application is calculated based on standard TAN contents in the manure from literature. These data are not influenced by changes in rations or housing systems. If the NH<sub>3</sub> emission after application of manure can be based on the calculated TAN contents in the

---

manure, effects of rations and housing systems on TAN also become visible in the emissions after application.

- Connection is made to internationally accepted concepts of NH<sub>3</sub> calculation methods (Reidy *et al.*, 2008), and also to the Emission Inventory Guidebook of EMEP/CORINAIR that is being used in the European and UNECE context ([www.eea.europa.eu/publications/emep-eea-guidebook-2013](http://www.eea.europa.eu/publications/emep-eea-guidebook-2013)).

In the methodology it is assumed that the relation between the TAN contents and the NH<sub>3</sub> emission progresses linearly, so that a linear emission factor is applied as percentage of the excreted TAN in manure. This assumption was also made in the former methodology based on total N (Oenema *et al.*, 2000) and has been found in experimental research (Velthof *et al.*, 2005).

The calculation method based on TAN takes into account the net mineralization of organic N that occurs in the manure (Annex 5). Methods to calculate the TAN excretion based on ration data have been drafted (Annexes 2, 3 and 4). This calculation is now done yearly in the WUM calculations, so that effects of changes in TAN (like for instance changes in roughage production and ration composition) on NH<sub>3</sub> emission can be well quantified. The actual ration compositions and N digestibility of the separate components are taken as the starting point for the TAN calculations instead of fixed TAN values or empirically averaged digestion values (Velthof *et al.*, 2012).

In poultry TAN is mainly uric acid. This is also called TAN in this report. It is however known that part of the uric acid in the animal house and outside manure storage may not have been converted to NH<sub>4</sub><sup>+</sup>. The amount of uric acid in the applied manure is uncertain, and as a result no correction is made for it. In subsequent sections uniform calculation rules are given based on TAN for all livestock categories.

Over time part of the TAN in manure is lost as gaseous N compounds. It is assumed that mineralization takes place directly after excretion. The calculations are performed as follows:

1. The TAN excretion by the animal is calculated as the excretion of N in urine.
2. The amount of TAN produced by net mineralization is calculated from the excretion of organic N in faeces.
3. The total amount of TAN in manure equals the sum of TAN excretion from step 1 and 2.
4. The emissions of NH<sub>3</sub> and other N compounds (N<sub>2</sub>, N<sub>2</sub>O, NO<sub>x</sub>) is calculated relative to the total amount of N in the manure, expressed as TAN to allow for a consistent calculation method.
5. After reduction of N losses in the animal house from the total TAN in manure, part of the manure is stored in outside storages and here too N losses occur.
6. The amount of TAN remaining after reduction of N losses in the animal house and/or outside storage, is applied to land (Chapters 8, 9 and 10).

In the next section the calculation steps are described in detail. Section 4.3 describes the conversion of the emission factors for gaseous NH<sub>3</sub> losses from animal housing and outside manure storages based on total N to emission factors based on TAN. Which data are needed for all this is explained further in Section 4.4.

## 4.2 Calculation method

Ammonia emissions from manure management are the sum of emissions from animal housing and outside manure storages.

$$\text{NH}_3 \text{ emissions } 3B = \sum \text{NH}_3 \text{ animal houses}_i + \text{NH}_3 \text{ manure storage}_i \quad (4.1)$$

In which

- NH<sub>3</sub> emissions 3B : Ammonia emission (kg NH<sub>3</sub>/year) for all defined livestock categories (i) within NFR category 3B manure management
- NH<sub>3</sub> animal houses<sub>i</sub> : Ammonia emission (kg NH<sub>3</sub>/year) from animal housing for livestock category (i)
- NH<sub>3</sub> manure storage<sub>i</sub> : Ammonia emission (kg NH<sub>3</sub>/year) from outside manure storages for livestock category (i)

---

#### 4.2.1 Ammonia emission from animal houses

The total NH<sub>3</sub> emission from animal houses is calculated from:

- Number of animals per livestock category;
- Total N excretion in the animal house per livestock category and manure management system (liquid or solid);
- Share of TAN in the excretion per livestock category (liquid or solid);
- Mineralization of organically bound N in manure stored in the animal house (liquid or solid);
- Average emission factors for NH<sub>3</sub> from animal housing per livestock category. This emission factor is weighted for the share of the different housing systems.

The NH<sub>3</sub> emission from animal houses for livestock category (i) is calculated as:

$$\text{NH}_3 \text{ animal houses}_i = \sum \text{TAN input}_{ij} \times \text{EF NH}_3\text{-N animal house}_{ij} \times 17/14 \quad (4.2)$$

In which

- NH<sub>3</sub> animal houses<sub>i</sub> : Ammonia emission (kg NH<sub>3</sub>/year) from animal housing for livestock category (i)
- TAN input<sub>ij</sub> : Sum of urine excretion and net N mineralization in the animal house (TAN; kg N/year) for livestock category (i) and manure management system (j)
- EF NH<sub>3</sub>-N animal house<sub>ij</sub> : Ammonia emission factor (% of TAN) for animal housings of livestock category (i) and manure management system (j)
- 17/14 : Conversion factor from NH<sub>3</sub>-N to NH<sub>3</sub> based on molecular weight

The TAN input for a given livestock category (i) and manure management system (j) is calculated as follows:

$$\text{TAN input}_{ij} = [ \text{number of animals in livestock category (i)} ] \times [ \text{fraction manure management system (j)} ] \times (\text{N excretion}_i \times \text{TAN fraction}_i + \text{N excretion}_i \times (1 - \text{TAN fraction}_i) \times \text{N mineralization}_j) \quad (4.3)$$

In which

- N excretion<sub>i</sub> : N excretion (kg N/animal) in the animal house for livestock category (i)
- TAN fraction<sub>i</sub> : Fraction urine N in the total N excretion in the animal house for livestock category (i)
- N mineralization<sub>j</sub> : net N mineralization in % of the organic N excretion for manure management system (j)

#### 4.2.2 Ammonia emission from manure storages

Part of the manure is stored in outside manure storages. From the initial TAN excreted by livestock (including mineralization), total gaseous nitrogen losses in the animal house are subtracted. These losses occur as NH<sub>3</sub>, NO<sub>x</sub>, N<sub>2</sub>O and N<sub>2</sub>. After multiplication by the fraction of manure stored, the TAN input into outside storages is established.

The total NH<sub>3</sub> emission from outside manure storages in a given year is calculated from:

- TAN input (urine N excretion and N mineralization in the animal house, minus total N losses in the animal house);
- Emission factors for NH<sub>3</sub> for outside manure storages per livestock category and manure management system (liquid or solid), expressed in percentage of the TAN input. In this emission factor the transfer of manure from the animal house to the outside storage is accounted for.

The NH<sub>3</sub> emission from outside manure storages for livestock category (i) is calculated as:

$$\text{NH}_3 \text{ manure storage}_i = \sum (\text{TAN input}_{ij} - \text{N losses animal house}_{ij}) \times \text{fraction storage}_{ij} \times \text{EF NH}_3\text{-N storage}_{ij} \times 17/14 \quad (4.4)$$

---

In which

- $NH_3$  manure storage<sub>i</sub> : Ammonia emission (kg  $NH_3$ /year) from outside manure storages for livestock category (i)
- N losses animal house<sub>ij</sub> : Sum of  $NH_3$ -N,  $N_2O$ -N,  $NO_x$ -N and  $N_2$ -N losses (kg N/year) from animal houses for livestock category (i) and manure management system (j)
- fraction storage<sub>ij</sub>: Fraction of manure stored outside for livestock category (i) and manure management system (j)
- EF  $NH_3$ -N storage<sub>ij</sub> : Ammonia emission factor (% of TAN) for outside storages of livestock category (i) and manure management system (j)
- 17/14 : Conversion factor from  $NH_3$ -N to  $NH_3$  based on molecular weight

Total N losses from animal houses for livestock category (i) and manure management system (j) are calculated as:

$$N \text{ losses animal house}_{ij} = TAN \text{ input}_{ij} \times (EF \text{ } NH_3\text{-N animal house}_{ij} + EF \text{ } N_2O\text{-N animal house}_{ij} + EF \text{ } NO_x\text{-N animal house}_{ij} + EF \text{ } N_2\text{-N animal house}_{ij}) \quad (4.5)$$

In which

- EF  $N_2O$ -N/ $NO_x$ -N/ $N_2$ -N animal house<sub>ij</sub> : Nitrous oxide/nitrogen oxides/nitrogen gas emission factor (% of TAN) for animal housing of animal category (i) and manure management system (j)

Emission factors for  $N_2O$ ,  $NO_x$  and  $N_2$  from animal housing are usually expressed as percentage of the N excretion (Oenema *et al.*, 2000). Nitrogen emissions as  $NO_x$  and  $N_2O$  from manure management are described in Chapters 5 and 6. For  $NH_3$  the emission factors are based on TAN. In line with the TAN-flow, the emission factors for  $N_2O$ ,  $NO_x$  and  $N_2$  have to be converted to percentages of TAN in order to determine the amount of TAN entering outside manure storages. Section 4.3.1 describes this conversion along with the emission factors for  $NH_3$  from animal housing. Losses as  $N_2$  are not reported, but only calculated for calculation of the TAN flow.

## 4.3 Emission factors

### 4.3.1 Emission factors for animal housing

$NH_3$  emission factors in the Netherlands are often derived from measurements, resulting from the measurement protocol for emission factors within the 'Regeling ammoniak en veehouderij' (Regulation ammonia and animal husbandry, Rav). The  $NH_3$  emission factors derived from the measurements are expressed per animal place. For the TAN-flow, these are converted into an emission factor as a % of TAN present taking into account the vacancy in housing. For all animal housing systems (k) per livestock category (i) the following calculation is performed.

$$EF \text{ } NH_3\text{-N animal house}_{ij} = \sum (EF \text{ } NH_3 \text{ animal house}_{ik} \times (14/17) / (1 - \text{fraction vac}_{ik})) / TAN \text{ input}_{ik} \times 100 \quad (4.6)$$

In which

- EF  $NH_3$ -N animal house<sub>ik</sub>: Ammonia emission factor (% of TAN excretion) for livestock category (i) and housing system (k)
- EF  $NH_3$  animal house<sub>ik</sub> : Ammonia emission factor (kg  $NH_3$ /animal place/year) for livestock category (i) and housing system (k)
- fraction vac<sub>ik</sub> : Fraction of vacancy per animal place for livestock category (i) and housing system (k), during the housing period
- TAN input<sub>ik</sub> : TAN input (kg N/animal/year) for livestock category (i) and housing system (k)
- 14/17 : Conversion factor from  $NH_3$  to  $NH_3$ -N based on molecular weight

In order to follow a consistent calculation methodology, the emission factors for N<sub>2</sub>O, NO<sub>x</sub> and N<sub>2</sub> from animal housing also need to be expressed as percentages of TAN. For all defined livestock categories (i) and manure management systems (j) the following calculations are performed:

$$EF_{N_2O-N/NO_x-N/N_2-N \text{ animal house}_{ij}} = EF_{N_2O/NO_x/N_2 \text{ animal house}_{ij}} \times N_{\text{excretion}_i} / TAN_{\text{input}_{ij}} \quad (4.7)$$

In which

EF<sub>N<sub>2</sub>O-N/NO<sub>x</sub>-N/N<sub>2</sub>-N animal house<sub>ij</sub></sub> : Emission factors (% of TAN excretion in the animal house) for N<sub>2</sub>O/NO<sub>x</sub>/N<sub>2</sub> from livestock category (i) and manure management system (j)

EF<sub>N<sub>2</sub>O/NO<sub>x</sub>/N<sub>2</sub> animal house<sub>ij</sub></sub> : Emission factors (% of total N excretion in the animal house) for N<sub>2</sub>O/NO<sub>x</sub>/N<sub>2</sub> from livestock category (i) and manure management system (j)

### 4.3.2 Emission factors for outside manure storages

The emission factor as percentage of the amount of TAN present at the start of the storage period is calculated from the proportion of the total amount of TAN that is excreted and mineralized in the animal house. For all livestock categories (i) and manure management systems (j), following calculations are performed:

$$EF_{NH_3-N \text{ storage}_{ij}} = EF_{NH_3 \text{ storage}_{ij}} \times ((N_{\text{excretion}_i} - N_{\text{losses animal housing}_{ij}}) / (TAN_{\text{input}_{ij}} - N_{\text{losses animal housing}_{ij}})) \quad (4.8)$$

In which

EF<sub>NH<sub>3</sub>-N storage<sub>ij</sub></sub> : Ammonia emission factor (% of TAN) for outside storages of livestock category (i) and manure management system (j)

EF<sub>NH<sub>3</sub> storage<sub>ij</sub></sub> : Ammonia emission factor (% of N stored) for outside manure storage of livestock category (i) and manure management system (j)

N losses animal housing<sub>ij</sub>: Sum of NH<sub>3</sub>-N, N<sub>2</sub>O-N, NO<sub>x</sub>-N and N<sub>2</sub>-N losses (kg N/year) from animal houses for livestock category (i) and manure management system (j)

Also in manure storages emissions of N<sub>2</sub>, N<sub>2</sub>O and NO<sub>x</sub> occur, but as emission factors for these include both animal housing and manure storage according to the IPCC guidelines, these are not calculated separately. Emissions from manure storages are therefore included in the EFs described in Section 4.3.1 (equation 4.7).

## 4.4 Activity data

Besides the animal numbers per livestock category, technical parameters on animal production (N excretion, TAN fraction) and information on management (housing systems, fraction storage) are needed to calculate emissions. An explanation on data needed for calculations on both the emissions from animal houses and emissions from manure storage is given in the next sections.

### 4.4.1 Emissions from animal houses

#### **Animal numbers**

Annex 1 presents an overview of the animal (sub-)categories being distinguished in the Agricultural Census. This categorization is also used within the NEMA calculations. Results are then aggregated towards the reporting categories as indicated in Section 4.1.

PVE (2005) estimated the Netherlands has 300,000 privately owned horses. This number is added to the result of the Agricultural Census, and resulting emissions are attributed to the 'Other' category.

---

### **N excretion per livestock category in the considered year**

For the N excretion in the animal house (taking into account the excretion on pasture land during grazing) the data of the Working group on Uniformity of calculations of Manure and mineral data (WUM) are used. These data have been published for the 1990-2008 time-series by WUM (2010) and for consecutive years in the publication series Animal manure and minerals (in Dutch; Van Bruggen, 2009 to 2014) available on the Statistics Netherlands (CBS) website, [www.cbs.nl](http://www.cbs.nl).

### **Fraction of TAN of the total N excretion**

The excretion of urine N (TAN) is calculated yearly based on data on ration composition and nitrogen digestibilities of the feed components in the ration and production parameters (Tamminga *et al.*, 2000, 2004). In Annexes 2, 3 and 4 the calculation method of urine N excretion for cattle, pigs and poultry is described for historic years (before 2009). For other grazing animals (horses, ponies, sheep and goats) the same methodology is used as for cattle. For rabbits and fur-bearing animals no data were available to calculate the TAN fraction in the N excretion. The share of these animals in the total NH<sub>3</sub> emission is limited and data on ration composition are difficult to obtain. To calculate TAN input would take a disproportionate amount of time. The TAN fractions for these animal categories are therefore assumed to be 70% of the excreted N (Velthof *et al.*, 2009). A more detailed explanation of TAN is given in Annexes 2, 3 and 4.

### **Mineralization/immobilization of organic N**

It is assumed that the N mineralization during storage of liquid manure in the animal house amounts to 10% of the organic N, based on research of Beline *et al.* (1998), see also Annex 5. For solid manure, a N immobilization of 25% is assumed. In poultry and fur-bearing animals no mineralization/immobilization is assumed.

### **NH<sub>3</sub> emission factor per livestock category and housing system**

The data of the most recent NH<sub>3</sub> emission factors in the Rav ('Regeling ammoniak en veehouderij'; Regulation ammonia and animal husbandry) are used where possible. If new information about a certain livestock category or housing system is available, the emission factor can however prelude the one in the Rav. In calculations of historic series the Rav values (or the previous UAV values) have to be used for the year concerned.

### **The shares of housing systems per livestock category**

The shares of housing systems per livestock category is based on the Agricultural Census. If for certain categories not enough information is available, other sources can be used like permit files of local authorities.

Based on research by Handhavingsamenwerking Noord-Brabant (2010, 2013) showing many of the air scrubbers required in environmental permits not being in use, implementation grades are corrected. In the years up and including 2009 it is assumed 40% was not functioning, decreasing by 8% a year to 16% in 2012. From then on an extrapolation is made, with a decrease of 4% per year to reach 0 in 2016 when all air scrubbers are to be equipped with electronic monitoring.

### **Lack of occupancy**

The lack of occupancy is given in Annex 9, based on Van Bruggen *et al.* (2015). With lack of occupancy the period in which the animal house is unoccupied between production rounds is meant. Vacancy through loss of animals, earlier selection of animals or other reasons for vacancies during a period of growth and rearing as described in Stichting Groen Label (1996) and Ogink *et al.* (2008) are not considered.

### **Emission factors for N<sub>2</sub>O, NO<sub>x</sub> and N<sub>2</sub>**

The emission factors for N<sub>2</sub>O, NO<sub>x</sub> and N<sub>2</sub> for animal houses and outside manure storages are based on the IPCC 2006 defaults for N<sub>2</sub>O and Oenema *et al.* (2000), setting the EF for NO<sub>x</sub> equal to N<sub>2</sub>O and for N<sub>2</sub> tenfold (liquid manure) or fivefold (solid manure). This results in the EFs, relative to N excreted by the animals as presented in Table 4.1. Additional information is presented in Chapters 5 (NO<sub>x</sub>) and 6 (N<sub>2</sub>O).

**Table 4.1**

*Emission factors for N<sub>2</sub>O and NO<sub>x</sub> and N<sub>2</sub> used to calculate other N losses from animal houses, expressed as percentage of N excretion*

| Manure type                                   | EF N <sub>2</sub> O-N (%) | EF NO <sub>x</sub> -N (%) | EF N <sub>2</sub> -N (%) |
|---|---------------------------|---------------------------|--------------------------|
| Liquid manure (cattle/pigs/other)             | 0.2                       | 0.2                       | 2.0                      |
| Solid manure (cattle/pigs/sheep/horses/other) | 0.5                       | 0.5                       | 2.5                      |
| Liquid manure (poultry)                       | 0.1                       | 0.1                       | 1.0                      |
| Solid manure (poultry)                        | 0.1                       | 0.1                       | 0.5                      |
| Deep bedding (goats)                          | 1.0                       | 1.0                       | 5.0                      |

Sources: IPCC (2006) and Oenema *et al.* (2000).

It has been examined whether better emission factors are available in the Netherlands. Based on this study it is concluded that only few data is available on emissions of N<sub>2</sub>O, NO<sub>x</sub> and N<sub>2</sub> from animal houses and outside manure storages, and that as a result the uncertainties on emission factors for N<sub>2</sub>O and NO<sub>x</sub> and N<sub>2</sub> are large. Because of the large uncertainties, it was decided to maintain the current methodology based on the IPCC guidelines and Oenema *et al.* (2000), however the measurements indicated that for the Dutch situation (largely without litter) the IPCC 2006 default values were rather high.

#### 4.4.2 Emissions from manure storages

##### **Fraction of the manure stored outside**

Information on the fractions of manure stored outside the animal house, are taken from the Agricultural Census complemented with data taken from literature. Annex 10 gives an overview of the percentages and sources.

## 4.5 Uncertainty and quality

The uncertainty estimate<sub>total</sub> concerns the root of the sum of uncertainty in the data sources used (AD<sub>unc</sub>) in the square and the uncertainty of the emission factors (EF<sub>unc</sub>) in the square. The extent of the total uncertainty is here primarily determined by the greatest AD or EF uncertainty.

$$\text{Uncertainty estimate}_{\text{total}} = \sqrt{(\text{AD}_{\text{unc}}^2 + \text{EF}_{\text{unc}}^2)} \quad (4.9)$$

The uncertainty estimates concerning the data sources (AD) and emission factors (EF) used, and the total uncertainty estimate, are listed in the following Table 4.2.

**Table 4.2**

*Uncertainty estimates for NH<sub>3</sub> from NFR category 3B manure management*

| EMEP  | Category                              | AD <sub>unc</sub> | EF <sub>unc</sub> | Uncertainty estimate <sub>total</sub> |
|-------|---------------------------------------|-------------------|-------------------|---------------------------------------|
| 3B1a  | Manure management of dairy cattle     | 2                 | 24                | 24                                    |
| 3B1b  | Manure management of non-dairy cattle | 2                 | 22-26             | 23-26                                 |
| 3B3   | Manure management of pigs             | 5-10              | 26-27             | 26-29                                 |
| 3B4gi | Manure management of laying hens      | 5-10              | 66                | 66                                    |

The uncertainty of NH<sub>3</sub> emissions as a result of manure management is based on expert judgement. Uncertainty in activity data (= animal numbers) is 2-10% depending on animal category (CBS, 2012) and uncertainty in the NH<sub>3</sub> EF for manure management, based on expert judgements, was estimated to be 22-66%.

A detailed overview of quality assurance and quality control is given in Annex 12. In this annex also some outlines on the verification of data are presented.

---

# 5 NO<sub>x</sub> emissions from manure management (NFR category 3B)

## 5.1 Scope and definition

This chapter describes the method and working processes for determining NO<sub>x</sub> emissions from manure management, using the following Nomenclature For Reporting (NFR) categories:

- 3B1a Dairy cattle
- 3B1b Non-dairy cattle
- 3B2 Sheep
- 3B3 Swine
- 3B4d Goats
- 3B4e Horses
- 3B4f Mules and asses
- 3B4gi Laying hens
- 3B4gii Broilers
- 3B4h Other animals

The category 3B4a (Buffalo) is reported as Not Occurring (NO), because these are not kept commercially in the Netherlands. Turkeys (3B4giii) and Other poultry (3B4giv; concerns ducks) are included within the category Broilers, and therefore reported as Included Elsewhere (IE). Emissions reported under category 3B concern only the NO<sub>x</sub> emissions from manure produced in animal houses, and then stored temporarily and/or processed before being transported elsewhere. The nitrogen oxides resulting from manure production on pasture land are reported under category 3D (NO<sub>x</sub> emissions from soil).

Although emissions are reported as nitrogen monoxide by NEMA, it is referred to as NO<sub>x</sub> in this report to prevent confusion with the notation key NO.

## 5.2 Calculation method

The amount of nitrogen in manure refers to the gross amount of N excreted, i.e. no reductions for ammonia and nitrous oxide emissions from animal houses and outside manure storages.

NO<sub>x</sub> emissions from livestock manure are calculated as follows:

$$\text{NO}_x \text{ emissions } 3B = \sum [ \text{number of animals in livestock category } (i) ] \times [ \text{fraction manure management system } (j) ] \times \text{N excretion}_i \times \text{EF NO}_x \text{ } 3B_{ij} \times 30/14 \quad (5.1)$$

In which

|                                     |   |
|-------------------------------------|---|
| NO <sub>x</sub> emissions 3B        | : NO <sub>x</sub> emissions (kg NO <sub>x</sub> , expressed as nitrogen monoxide) for all livestock categories (i) within NFR category 3B manure management |
| N excretion <sub>i</sub>            | : N excretion (kg N/animal) for livestock category (i)  |
| EF NO <sub>x</sub> 3B <sub>ij</sub> | : Emission factor (kg NO <sub>x</sub> -N/kg N excreted in the animal house) for livestock category (i) and manure management system (j)                     |
| 30/14                               | : Conversion factor from kg NO <sub>x</sub> -N to kg NO <sub>x</sub> , expressed as nitrogen monoxide   |

---

## 5.3 Emission factors

The NEMA model uses the emission factors in following Table 5.1, derived from Oenema *et al.* (2000) based on IPCC (2006).

---

Table 5.1

*Emission factors for NO<sub>x</sub> from manure management*

| Manure management system | Emission factors in kg NO <sub>x</sub> -N/kg N manure excreted in the animal house |
|--------------------------|--|
| Liquid manure            | 0.002  |
| Solid manure             | 0.005  |
| Liquid poultry manure    | 0.001  |
| Solid poultry manure     | 0.001  |
| Goats deep bedding       | 0.01   |

Sources: Oenema *et al.* (2000) based on IPCC (2006).

## 5.4 Activity data

### Animal numbers

Annex 1 presents an overview of the animal (sub-)categories being distinguished in the Agricultural Census. This categorization is also used within the NEMA calculations, and results are then grouped towards reporting categories as indicated.

PVE (2005) estimated the Netherlands has 300,000 privately owned horses. This number is added to the result of the Agricultural Census, and resulting emissions are attributed to the 'Other' category.

### Nitrogen excretion per animal and manure management system

The N excretion per animal, as well as the differentiation between solid and liquid manure, are determined by the WUM (Working group on Uniformity of calculations of Manure and mineral data). A more detailed subdivision in solid and liquid manure is made in the working group NEMA. These figures have been published for the 1990-2008 time-series by WUM (2010) and for consecutive years in the publication series Animal manure and minerals (in Dutch; Van Bruggen, 2009 to 2014) available on the Statistics Netherlands (CBS) website, [www.cbs.nl](http://www.cbs.nl). Since 2006, horse manure is also included in the WUM calculations. The preceding years are assumed to be the same as the figures for 2006.

## 5.5 Uncertainty and quality

The uncertainty estimate<sub>total</sub> concerns the root of the sum of uncertainty in the data sources used (AD<sub>unc</sub>) in the square and the uncertainty of the emission factors (EF<sub>unc</sub>) in the square. The extent of the total uncertainty is here primarily determined by the greatest AD or EF uncertainty.

$$\text{Uncertainty estimate}_{\text{total}} = \sqrt{(AD_{\text{unc}}^2 + EF_{\text{unc}}^2)} \quad (5.2)$$

The uncertainty of NO<sub>x</sub> emissions as a result of manure management is based on expert judgement. Uncertainty in activity data (= animal numbers) is 2-10% depending on animal category (CBS, 2012) and uncertainty in the NO<sub>x</sub> EF for manure management, based on expert judgements, was estimated to be 75-86%.

A detailed overview of quality assurance and quality control is given in Annex 12. In this annex also some outlines on the verification of data are presented.

---

# 6 N<sub>2</sub>O emissions from manure management (CRF sector 3B)

## 6.1 Scope and definition

This chapter describes the method and working processes for determining N<sub>2</sub>O emissions from manure management. In the Common Reporting Format (CRF) the following source categories are distinguished:

- 3B1a Mature dairy cattle
- 3B1b Other mature cattle
- 3B1c Growing cattle
- 3B2 Sheep
- 3B3 Swine
- 3B4d Goats
- 3B4e Horses
- 3B4f Mules and asses
- 3B4g Poultry
- 3B4h Other livestock (rabbits and fur-bearing animals)
- 3B5 Indirect N<sub>2</sub>O emissions

The source categories 3B4a Buffalo, 3B4b Camels and 3B4c Deer are reported as Not Occurring (NO), because these are not kept commercially in the Netherlands.

Emissions reported under category 3B concern only the N<sub>2</sub>O emissions from manure produced in animal houses, and then stored temporarily and/or processed before being transported elsewhere. The nitrous oxide resulting from manure production on pasture land is reported under category 3D (Chapter 10; N<sub>2</sub>O emissions from crop production and agricultural soils).

Nitrous oxide emissions from livestock manure management depend on the nitrogen and carbon content of the manure, the amount of time the manure is stored and the treatment method used. During storage the manure often becomes low-oxygen, which slows the nitrification process and therefore denitrification remains low.

Nitrification is the process whereby, under high-oxygen circumstances, ammonia (NH<sub>4</sub><sup>+</sup>) is converted by bacteria into nitrate. Nitrous oxide can be formed as a by-product, particularly if the nitrification is limited through lack of oxygen. Nitrification does not require any organic substances (volatile solids) to be present. Straw-rich solid manure and poultry manure can possess a relatively open and loose structure, where O<sub>2</sub> can diffuse far more easily than in liquid manure, enabling nitrification.

Denitrification is the process whereby, under low-oxygen circumstances, bacteria can convert nitrate (NO<sub>3</sub><sup>-</sup>) into the gaseous nitrogen compound N<sub>2</sub>, with N<sub>2</sub>O as a by-product. Organic substances (volatile solids) are used as an energy source. Denitrification in animal houses and manure storages is fully depending on the nitrification process, which has to supply the oxidized nitrogen compounds.

N<sub>2</sub>O emissions from solid manure are higher than those from liquid manure, because there is very little nitrification in the latter due to the lack of oxygen.

## 6.2 Calculation method

Nitrous oxide emissions from manure management are calculated as:

$$\text{N}_2\text{O emissions 3B} = (\text{N}_2\text{O-N emission direct} + \text{N}_2\text{O-N emission indirect}) \times 44/28 \quad (6.1)$$

---

In which

- N<sub>2</sub>O emissions 3B : Nitrous oxide emissions (kg N<sub>2</sub>O/year) for all livestock categories (i) within CRF sector 3B manure management
- N<sub>2</sub>O-N emission direct : Direct nitrous oxide emission (kg N<sub>2</sub>O-N/year) from manure management
- N<sub>2</sub>O-N emission indirect : Indirect nitrous oxide emission (kg N<sub>2</sub>O-N/year) following atmospheric deposition of NH<sub>3</sub> and NO<sub>x</sub> from manure management
- 44/28 : Conversion factor from N<sub>2</sub>O-N to N<sub>2</sub>O

### 6.2.1 Direct N<sub>2</sub>O emissions from manure management

The amount of nitrogen in manure refers to the gross amount, i.e. no reductions for ammonia and nitric oxide emissions from animal houses and storage.

Direct N<sub>2</sub>O emissions from livestock manure are calculated as follows:

$$\text{N}_2\text{O-N emission direct} = \sum [\text{number of animals in livestock category (i)}] \times \text{N excretion}_i \times [\text{fraction manure management system (j)}] \times \text{EF N}_2\text{O direct 3B}_j \quad (6.2)$$

In which

- N excretion<sub>i</sub> : N excretion (kg N/animal) of livestock category (i)
- EF N<sub>2</sub>O direct 3B<sub>j</sub> : Emission factor for manure management system (j) in kg N<sub>2</sub>O-N/kg N excreted manure

#### **Comparison to IPCC methodology**

The aforementioned method complies with that described by the IPCC (IPCC, 2006; p. 10.52). Therefore the total amount of manure produced is multiplied by an emission factor, without subtracting ammonia and nitric oxide emissions.

Default (Tier 1) values are used for the emission factors. The calculations are made within the National Emission Model for Agriculture (NEMA), based on the best available data on division over liquid and solid manure.

### 6.2.2 Indirect N<sub>2</sub>O emissions from manure management

Indirect nitrous oxide emission from manure management are calculated by multiplying total NH<sub>3</sub> en NO<sub>x</sub> emissions from animal housing and NH<sub>3</sub> from manure storage with an emission factor:

$$\text{N}_2\text{O emission indirect} = (\text{NH}_3 \text{ emissions 3B} \times 14/17 + \text{NO}_x \text{ emissions 3B} \times 14/30) \times \text{EF N}_2\text{O indirect 3B} \quad (6.3)$$

In which

- N<sub>2</sub>O emission indirect : Indirect nitrous oxide emission (kg N<sub>2</sub>O-N/year) following atmospheric deposition of NH<sub>3</sub> and NO<sub>x</sub> from manure management
- NH<sub>3</sub> emissions 3B : Ammonia emission (kg NH<sub>3</sub>/year) for all defined livestock categories (i) within NFR category 3B manure management
- 14/17 : Conversion factor from NH<sub>3</sub> to NH<sub>3</sub>-N
- NO<sub>x</sub> emissions 3B : NO<sub>x</sub> emissions (kg NO<sub>x</sub>, expressed as nitrogen monoxide) for all defined livestock categories (i) within NFR category 3B manure management
- 14/30 : Conversion factor from NO<sub>x</sub> (expressed as nitrogen monoxide) to NO<sub>x</sub>-N
- EF N<sub>2</sub>O indirect 3B : Nitrous oxide emission factor for indirect emission following atmospheric deposition of NH<sub>3</sub> and NO<sub>x</sub>

---

## 6.3 Emission factors

### 6.3.1 Direct N<sub>2</sub>O emissions from manure management

The NEMA model uses the default IPCC 2006 emission factors, in following Table 6.1.

---

**Table 6.1**

*Emission factors for N<sub>2</sub>O from manure management*

| Manure management system | Emission factors in kg N <sub>2</sub> O-N/kg N manure excreted in the animal house |
|--------------------------|--|
| Liquid manure            | 0.002  |
| Solid manure             | 0.005  |
| Liquid poultry manure    | 0.001  |
| Solid poultry manure     | 0.001  |
| Goats deep bedding       | 0.01   |

Source: IPCC (2006).

### 6.3.2 Indirect N<sub>2</sub>O emissions from manure management

The IPCC 2006 default EF of 0.01 kg N<sub>2</sub>O-N/kg N emitted as NH<sub>3</sub> and NO<sub>x</sub> from animal houses and outside manure storages is used.

## 6.4 Activity data

### **Animal numbers**

Annex 1 presents an overview of the animal (sub-)categories being distinguished in the Agricultural Census. This categorization is also used within the NEMA calculations, and results are then grouped towards reporting categories as indicated.

In sheep, goats, rabbits and fur-bearing animals, both young and male animals are being accounted for in the N excretion of the mother animal. For pigs, the excretion of piglets is included within the excretion of sows. Therefore the number of female animals is used in the calculations for N<sub>2</sub>O emissions from manure management.

PVE (2005) estimated the Netherlands has 300,000 privately owned horses. This number is added to the result of the Agricultural Census, and resulting emissions are attributed to agriculture. In contrast to large-scale pollutants, the Netherlands has chosen not to report greenhouse gas emissions under the 'Other' category.

### **Nitrogen excretion per animal and manure management system**

The N excretion per animal, as well as the differentiation between solid and liquid manure, are determined by the WUM (Working group on Uniformity of calculations of Manure and mineral data). A more detailed subdivision in solid and liquid manure is made in the working group NEMA. These figures have been published for the 1990-2008 time-series by WUM (2010) and for consecutive years in the publication series Animal manure and minerals (in Dutch; Van Bruggen, 2009 to 2014) available on the Statistics Netherlands (CBS) website, [www.cbs.nl](http://www.cbs.nl). Since 2006, horse manure is also included in the WUM calculations. The preceding years are assumed to be the same as the figures for 2006.

---

## 6.5 Uncertainty and quality

A Tier 1 uncertainty analysis is implemented every year before the NIR is submitted by the ER, based on the greenhouse gas inventory and in compliance with IPCC Guidelines. The assumptions used and the results thereof are described in an annex to the NIR. In addition to this, where included in the QA/QC-programme for the relevant period, extra analyses are implemented regularly in specific situations, which include any updating of the Tier 2 uncertainty analyses.

The Tier 2 uncertainty assessment was last updated in 2009. This assessment showed that a Tier 1 uncertainty assessment is sufficiently reliable and that Tier 2 uncertainty assessments need only be implemented at periodic intervals of around 5 years, unless a major change in an important source is sufficient to require earlier reassessment.

### Source specific uncertainty

The uncertainty estimate<sub>total</sub> concerns the root of the sum of uncertainty in the data sources used (AD<sub>unc</sub>) in the square and the uncertainty of the emission factor (EF<sub>unc</sub>) in the square. The extent of the total uncertainty is here primarily determined by the greatest AD or EF uncertainty.

$$\text{Uncertainty estimate}_{\text{total}} = \sqrt{(\text{AD}_{\text{unc}}^2 + \text{EF}_{\text{unc}}^2)} \quad (6.4)$$

The uncertainty estimates concerning the data sources (AD) and emission factors (EF) used, and the total uncertainty estimate, are listed in the following Table 6.2.

---

Table 6.2

*Uncertainty estimates for N<sub>2</sub>O from CRF sector 3B manure management*

| IPCC | Category                         | AD <sub>unc</sub> | EF <sub>unc</sub> | Uncertainty estimate <sub>total</sub> |
|------|----------------------------------|-------------------|-------------------|---------------------------------------|
| 3B   | Emissions from manure management | 10                | 100               | 100                                   |

The uncertainty in the N<sub>2</sub>O emission from the management of manure from cattle and pigs was estimated to be approximately 100%, annually. The uncertainty in the amount of animal manure (10%) was based on a 5% uncertainty in animal numbers and a 5 to 10% uncertainty in excretion per animal (RIVM, 1999). The resulting uncertainty of 7 to 11% was rounded off to 10%. The uncertainty in the N<sub>2</sub>O emission factors for manure management, based on expert judgements, was estimated to be 100% (Olivier *et al.*, 2009).

A detailed overview of quality assurance and quality control is given in Annex 12. In this annex also some outlines on the verification of data are presented.

---

# 7 PM<sub>10/2.5</sub> emissions from animal housing (NFR category 3B)

## 7.1 Scope and definition

This chapter describes the method and working processes for determining PM<sub>10</sub> and PM<sub>2.5</sub> emissions from animal housing, using the following Nomenclature For Reporting (NFR) categories:

- 3B1a Dairy cattle
- 3B1b Non-dairy cattle
- 3B2 Sheep
- 3B3 Swine
- 3B4d Goats
- 3B4e Horses
- 3B4f Mules and asses
- 3B4gi Laying hens
- 3B4gii Broilers
- 3B4h Other animals

The category 3B4a (Buffalo) is reported as Not Occurring (NO), because these are not kept commercially in the Netherlands. Categories 3B4giii (Turkeys) and 3B4giv (Other poultry) are included within the category Broilers (Included Elsewhere, IE).

Particulate matter emissions from agriculture mainly originate from animal houses, and consist of skin, manure, feed and bedding particles. Poultry is the main source category of PM<sub>10</sub> and PM<sub>2.5</sub> in agriculture. Housing systems for laying hens that produced liquid manure were replaced by systems that produce solid manure, which leads to a higher emission of particulate matter. Pigs and cattle also contribute to the particulate matter production but to a much smaller extent. Since more housing systems for pigs use air scrubbers the emission of particulate matter decreases.

## 7.2 Calculation method

Shares of used housing systems are derived from the Agricultural Census, and the emissions are calculated by multiplying the number of animals per housing system with emission factors for PM<sub>10</sub> and PM<sub>2.5</sub> in grams/animal/year.

$$\text{PM emissions 3B} = \sum [ \text{number of animals per livestock category (i)} ] \times [ \text{fraction animal housing system (k)} ] \times \text{EF PM 3B}_{ik} / 1,000 \quad (7.1)$$

In which

|                        |   |
|------------------------|---|
| PM emissions 3B        | : PM emissions (kg PM <sub>10</sub> or PM <sub>2.5</sub> /year) for all livestock categories (i) and housing systems (k) within NFR category 3B manure management |
| EF PM 3B <sub>ik</sub> | : Emission factor (g PM <sub>10</sub> or PM <sub>2.5</sub> /year) for livestock category (i) and animal housing system (k)  |
| 1,000                  | : Conversion factor from grams to kilograms   |

## 7.3 Emission factors

The emission factors are based on a measurement program conducted by Wageningen UR Livestock Research between 2007 and 2009 (publication series 'Particulate matter emission from animal houses', in Dutch; Mosquera *et al.*, 2009a, 2009b, 2009c, 2010a, 2010b, 2010c and Winkel *et al.*, 2009a, 2009b, 2010).

Table 7.1 gives an overview of housing systems and emission factors used for PM<sub>10</sub> and PM<sub>2.5</sub>.

**Table 7.1**

*Emission factors for PM<sub>10</sub> and PM<sub>2.5</sub> from animal housing (g/animal/year)*

|   | Housing system             | PM <sub>10</sub> | PM <sub>2.5</sub> |
|---|----------------------------|------------------|-------------------|
| <b>Dairy cattle</b>                                       |                            |                  |                   |
| Female young stock under 1 year                           | Traditional                | 37.7             | 10.4              |
| Male young stock under 1 year                             | Traditional                | 170.1            | 46.8              |
| Female young stock, 1-2 years                             | Traditional                | 37.7             | 10.4              |
| Male young stock, 1-2 years                               | Traditional                | 170.1            | 46.8              |
| Female young stock, 2 years and over                      | Traditional                | 117.8            | 32.5              |
| Cows in milk and in calf                                  | Tie-stall system           | 80.8             | 22.3              |
|   | Cubicle system, grazing    | 117.8            | 32.5              |
|   | Cubicle system, no grazing | 147.5            | 40.6              |
| Bulls for service 2 years and over                        | Traditional                | 170.1            | 46.8              |
| <b>Cattle for fattening</b>                               |                            |                  |                   |
| Meat calves, for white veal production                    | Traditional                | 35.7             | 9.8               |
|   | Air scrubber               | 25.0             | 6.9               |
| Meat calves, for rosé veal production                     | Traditional                | 35.7             | 9.8               |
|   | Air scrubber               | 25.0             | 6.9               |
| Female young stock under 1 year                           | Traditional                | 37.7             | 10.4              |
| Male young stock (incl. young bullocks) under 1 year      | Traditional                | 170.1            | 46.8              |
| Female young stock, 1-2 years                             | Traditional                | 37.7             | 10.4              |
| Male young stock (incl. young bullocks), 1-2 years        | Traditional                | 170.1            | 46.8              |
| Female young stock, 2 years and over                      | Traditional                | 86.2             | 23.8              |
| Male young stock (incl. young bullocks), 2 years and over | Traditional                | 170.1            | 46.8              |
| Suckling cows (incl. fattening/grazing), 2 years and over | Traditional                | 86.2             | 23.8              |
| <b>Pigs</b>   |                            |                  |                   |
| Piglets   | Traditional                | 81.2             | 2.1               |
|   | Air scrubber               | 56.8             | 1.5               |
|   | Combined air scrubber      | 24.4             | 0.6               |
| Fattening pigs  | Traditional                | 156.2            | 7.3               |
|   | Air scrubber               | 109.3            | 5.1               |
|   | Combined air scrubber      | 46.9             | 2.2               |
| Gilts not yet in pig                                      | Traditional                | 156.2            | 7.3               |
|   | Air scrubber               | 109.3            | 5.1               |
|   | Combined air scrubber      | 46.9             | 2.2               |
| Sows  | Traditional                | 180.4            | 14.2              |
|   | Air scrubber               | 126.3            | 9.9               |
|   | Combined air scrubber      | 54.1             | 4.3               |
| Sows with piglets   | Traditional                | 409.6            | 21.8              |

## 7.4 Activity data

### Animal numbers

Annex 1 presents an overview of the animal (sub-)categories being distinguished in the Agricultural Census. This categorization is also used within the NEMA calculations, and results are then grouped towards reporting categories as indicated.

PVE (2005) estimated the Netherlands has 300,000 privately owned horses. This number is added to the result of the Agricultural Census, and resulting emissions are attributed to the 'Other' category.

### The shares of housing systems per livestock category

The shares of housing systems per livestock category is based on the Agricultural Census. If for certain categories not enough information is available, other sources can be used like permit files of local authorities.

---

Based on research by Handhavingsamenwerking Noord-Brabant (2010, 2013) showing many of the air scrubbers required in environmental permits not being in use, implementation grades are corrected. In the years up and including 2009 it is assumed 40% was not functioning, decreasing by 8% a year to 16% in 2012. From then on an extrapolation is made, with a decrease of 4% per year to reach 0 in 2016 when all air scrubbers are to be equipped with electronic monitoring.

## 7.5 Uncertainty and quality

The uncertainty estimate<sub>total</sub> concerns the root of the sum of uncertainty in the data sources used ( $AD_{unc}$ ) in the square and the uncertainty of the emission factors ( $EF_{unc}$ ) in the square. The extent of the total uncertainty is here primarily determined by the greatest AD or EF uncertainty.

$$\text{Uncertainty estimate}_{total} = \sqrt{(AD_{unc}^2 + EF_{unc}^2)} \quad (7.2)$$

The uncertainty of  $PM_{10/2.5}$  emissions as a result of manure management is based on expert judgement and measurement variation. Uncertainty in activity data (= animal numbers) is 2-10% depending on animal category (CBS, 2012) and uncertainty in the  $PM_{10/2.5}$  EF for manure management, based on measurement variation, was estimated to be 2-55%.

A detailed overview of quality assurance and quality control is given in Annex 12. In this annex also some outlines on the verification of data are presented.

# 8 NH<sub>3</sub> emissions from crop production and agricultural soils (NFR category 3D)

## 8.1 Scope and definition

This chapter describes the method and working processes for determining NH<sub>3</sub> emissions from crop production and agricultural soils, using the following Nomenclature For Reporting (NFR) categories:

- 3Da1 Inorganic N-fertilizers (includes also urea application)
- 3Da2a Livestock manure applied to soils
- 3Da2b Sewage sludge applied to soils
- 3Da2c Other organic fertilizers applied to soils (including compost)
- 3Da3 Urine and dung deposited by grazing animals
- 3Da4 Crop residues applied to soils
- 3De Cultivated crops

Ammonia emissions occur in all subcategories describing N inputs to the soil (i.e. 3Da1 up to 3Da4), and during crop cultivation (3De). Subcategory 3F Field burning of agricultural residues is reported as Not Occurring (NO) since field burning is prohibited in the Netherlands. In the categories 3Df Use of pesticides and 3I Agriculture other, no ammonia emissions occur either.

The amount of TAN and organic N that remains in manure after outside storage, is applied to the soil. It is assumed that manure stocks in storage remain equal, so no correction is made for manure stored longer than 1 year. The amount of TAN in manure applied to soil is calculated from:

- Total N (urine N and faecal N) excretion in the animal house;
- Mineralization of organic N in storage;
- Losses of NH<sub>3</sub>, N<sub>2</sub>O, NO<sub>x</sub> and N<sub>2</sub> inside the animal house and during outside storage;
- Amount of manure that is incinerated, exported or processed and subsequently used outside agriculture;
- Manure used outside agriculture (hobby farming and application on nature areas).

Manure can also be applied to soils directly via grazing animals. Emissions during grazing are calculated directly from TAN. Besides manure application and grazing, the application of inorganic N-fertilizer (including rinsing liquid of air scrubbers) to agricultural soils is a source of emission of NH<sub>3</sub>. NH<sub>3</sub> emission from fertilizer occurs only if the fertilizer contains urea, or when ammonium (NH<sub>4</sub><sup>+</sup>) is applied to calcareous soils.

## 8.2 Calculation method

Total ammonia emissions from crop production and agricultural soils are the sum of:

$$\text{NH}_3 \text{ emissions } 3D = \text{NH}_3 \text{ fertilizer} + \text{NH}_3 \text{ manure application} + \text{NH}_3 \text{ sewage sludge} + \text{NH}_3 \text{ compost} + \text{NH}_3 \text{ grazing} + \text{NH}_3 \text{ crop residues} + \text{NH}_3 \text{ ripening crops} \quad (8.1)$$

In which

NH<sub>3</sub> emissions 3D : Ammonia emission (kg NH<sub>3</sub>/year) from CRF sector 3D crop production and agricultural soils

For all distinguished source categories, a calculation method is available within the National Emission Model for Agriculture (NEMA). The amount of TAN in livestock manure available for application, follows from the TAN excretion minus N emissions in animal houses and during manure storage, using a

balance method to model N flows in agriculture. Also TAN excreted on pasture land during grazing is part of this scheme. The other N supply sources (e.g. inorganic N-fertilizer, sewage sludge, compost and crop residues) are in the flow model as well.

### 8.2.1 Ammonia emission from inorganic N-fertilizer application

The ammonia emission from inorganic N-fertilizer is calculated from:

- Amount of N applied per type of inorganic N-fertilizer;
- Emission factor per type of inorganic N-fertilizer (Section 8.3.1).

NH<sub>3</sub> emissions from inorganic N-fertilizer application are calculated as follows.

$$\text{NH}_3 \text{ fertilizer} = \sum \text{EF NH}_3 \text{ fertilizer}_i \times \text{N fertilizer}_i \times 17/14 \quad (8.2)$$

In which

|  |   |
|--|---|
| NH <sub>3</sub> fertilizer                 | : Ammonia emission (kg NH <sub>3</sub> /year) from inorganic N-fertilizers            |
| EF NH <sub>3</sub> fertilizer <sub>i</sub> | : NH <sub>3</sub> emission factor of inorganic N-fertilizer (i) in % of the applied N |
| N fertilizer <sub>i</sub>                  | : Total amount applied inorganic N-fertilizer (i) in kg N                             |
| 17/14                                      | : Conversion factor from NH <sub>3</sub> -N to NH <sub>3</sub>                        |

### 8.2.2 Ammonia emission from manure application

The amount of TAN that is applied with manure is calculated from:

- TAN input in the animal house (the sum of the urine N excretion and the TAN released through mineralization during storage);
- Losses in NH<sub>3</sub> and other N compounds in animal houses and manure storages;
- Amount N in the manure that is processed and marketed outside agriculture (assumption is that in this no NH<sub>3</sub> emission occurs);
- Amount N that is exported or imported through manure (net export);
- It is assumed that the yearly stock of N stored in manure does not change.

The NH<sub>3</sub> emission from manure application is calculated as:

$$\text{NH}_3 \text{ manure application} = \sum (\text{TAN applied on grassland}_{ij} \times \text{fraction application technique on grassland}_j \times \text{EF application technique on grassland}_j + \text{TAN applied on cropland}_{ij} \times \text{fraction application technique on cropland}_j \times \text{EF application technique on cropland}_j) \times 17/14 \quad (8.3)$$

In which

|  |   |
|--|---|
| NH <sub>3</sub> manure application                       | : Ammonia emission from manure applied to agricultural soils (kg NH <sub>3</sub> /year)                                   |
| TAN applied on grassland <sub>ij</sub>                   | : Amount of TAN in manure (kg N/year) of livestock category (i) and manure management system (j) applied to grassland     |
| fraction application technique on grassland <sub>j</sub> | : Fractions of manure application techniques for manure management system (j) used on grassland                           |
| EF application technique on grassland <sub>j</sub>       | : Ammonia emission factor (% of TAN) for manure application techniques for manure management system (j) used on grassland |
| TAN applied on cropland <sub>ij</sub>                    | : Amount of TAN in manure (kg N/year) of livestock category (i) and manure management system (j) applied to cropland      |
| fraction application technique on cropland <sub>j</sub>  | : Fractions of manure application techniques for manure management system (j) used on cropland                            |
| EF application technique on cropland <sub>j</sub>        | : Ammonia emission factor (% of TAN) for manure application techniques for manure management system (j) used on cropland  |
| 17/14  | : Conversion factor from NH <sub>3</sub> -N to NH <sub>3</sub>  |

The NH<sub>3</sub> emission is calculated for different manure application techniques. For grassland the following application techniques are distinguished (Section 8.3.2): surface spreading, shallow injection, trailing hose and slit coulter application. For cropland surface spreading, injection/full coverage, incorporation in 1 track and incorporation in 2 tracks are distinguished.

The amount of TAN available per livestock category/manure type, is calculated by subtracting N emissions in animal houses and during manure storage from the TAN excretion in the animal house. Part of the manure is used outside agriculture, processed or exported. The amount of manure per livestock category (i) and manure management system (j) that is available for application, is found by subtracting these amounts from the initial TAN excretion:

$$\text{TAN for application}_{ij} = \text{TAN input}_i \times [\text{fraction manure management system (j)}] - \text{N losses animal housing}_{ij} - \text{NH}_3 \text{ storage}_{ij} - \text{N processed}_{ij} - \text{N export}_{ij} \quad (8.4)$$

In which

|                                       |  |
|---------------------------------------|--|
| TAN for application <sub>ij</sub>     | : Amount of manure (kg N) that per livestock category (i) and manure management system (j) is applied to agricultural soils  |
| TAN input <sub>i</sub>                | : TAN excretion (kg N) in the animal house for livestock category (i)  |
| N losses animal housing <sub>ij</sub> | : Sum of NH <sub>3</sub> , N <sub>2</sub> O, NO <sub>x</sub> and N <sub>2</sub> losses (kg N) from animal houses for livestock category (i) and manure management system (j) |
| NH <sub>3</sub> storage <sub>ij</sub> | : NH <sub>3</sub> emission from outside manure storages for livestock category (i) and manure management system (j) in kg N  |
| N processed <sub>ij</sub>             | : Amount of manure that per livestock category (i) and manure management system (j) is processed in kg N   |
| N export <sub>ij</sub>                | : Amount of manure that per livestock category (i) and manure management system (j) is exported in kg N, with import denoted as negative export                              |

It is assumed that the imported manure has the same TAN fraction in total N as the manure coming from the animal house and storage.

The total amounts of liquid and solid manure are then divided over grassland and cropland, see Section 8.4.2. The NH<sub>3</sub> emission from application of manure to grassland and cropland is calculated from i) the amount of TAN that is applied to grassland and cropland through manure and ii) the emission factors for NH<sub>3</sub> emission for application by different techniques on cropland and grassland (Section 8.3.2).

### 8.2.3 Ammonia emission from sewage sludge application

In the calculation of NH<sub>3</sub> emission from sewage sludge application a distinction is made between liquid and solid sludge, with different TAN fractions. All sewage sludge, both liquid and solid is assumed to be surface applied on cropland:

$$\text{NH}_3 \text{ sewage sludge} = (\text{N sewage sludge} \times \text{liquid fraction} \times \text{TAN liquid} \times \text{EF NH}_3 \text{ liquid} + \text{N sewage sludge} \times \text{solid fraction} \times \text{TAN solid} \times \text{EF NH}_3 \text{ solid}) \times 17/14 \quad (8.5)$$

In which

|                               |   |
|-------------------------------|---|
| NH <sub>3</sub> sewage sludge | : Ammonia emission (kg NH <sub>3</sub> /year) from sewage sludge                        |
| N sewage sludge               | : Amount of sewage sludge (kg N) applied to agricultural soils                          |
| liquid fraction               | : Fraction sewage sludge in liquid form   |
| TAN liquid                    | : Fraction TAN in liquid sewage sludge  |
| EF NH <sub>3</sub> liquid     | : Ammonia emission factor (kg NH <sub>3</sub> -N/kg N applied) for liquid sewage sludge |
| solid fraction                | : Fraction sewage sludge in solid form  |
| TAN solid                     | : Fraction TAN in solid sewage sludge   |
| EF NH <sub>3</sub> solid      | : Ammonia emission factor (kg NH <sub>3</sub> -N/kg N applied) for solid sewage sludge  |
| 17/14                         | : Conversion factor from NH <sub>3</sub> -N to NH <sub>3</sub>                          |

## 8.2.4 Ammonia emission from other organic fertilizers (compost)

Two sources of compost are considered (from organic waste or green refuse), however it is assumed that the fraction of TAN in both is equal. All compost is surface applied on cropland:

$$\text{NH}_3 \text{ compost} = (\text{N organic waste compost} + \text{N green refuse compost}) \times \text{TAN compost} \times \text{EF NH}_3 \text{ compost} \times 17/14 \quad (8.6)$$

In which

|                            |   |
|----------------------------|---|
| NH <sub>3</sub> compost    | : Ammonia emission (kg NH <sub>3</sub> /year) from compost                    |
| N organic waste compost    | : Amount of organic waste compost (kg N) applied to agricultural soils        |
| N green refuse compost     | : Amount of green refuse compost (kg N) applied to agricultural soils in kg N |
| TAN compost                | : Fraction TAN in compost   |
| EF NH <sub>3</sub> compost | : Ammonia emission factor (kg NH <sub>3</sub> -N/kg N applied) for compost    |
| 17/14                      | : Conversion factor from NH <sub>3</sub> -N to NH <sub>3</sub>                |

NEMA also calculates the NH<sub>3</sub> emissions for compost use outside agriculture, but these are allocated to NFR sector 6A Other.

## 8.2.5 Ammonia emission from grazing

The ammonia emission from grazing is calculated from:

- N excretion on pasture land per grazing animal category, in kg N calculated on a yearly basis by the WUM;
- Share TAN in the N excretion during grazing, % of total N excretion (Annex 2);
- Emission factors for grazing, in % of TAN on pasture land (Section 8.3.5).

The total NH<sub>3</sub> emission from grazing for all livestock categories (i) is calculated as:

$$\text{NH}_3 \text{ pasture} = \sum [\text{number of animals in livestock category (i)}] \times \text{TAN pasture}_i \times \text{EF NH}_3 \text{ grazing} \times 17/14 \quad (8.7)$$

In which

|                            |  |
|----------------------------|--|
| NH <sub>3</sub> pasture    | : Ammonia emissions (kg NH <sub>3</sub> /year) from grazing            |
| TAN pasture <sub>i</sub>   | : TAN excretion on pasture land (kg N/year) for livestock category (i) |
| EF NH <sub>3</sub> grazing | : Emission factor for grazing in % of TAN excretion                    |
| 17/14                      | : Conversion factor from NH <sub>3</sub> -N to NH <sub>3</sub>         |

The TAN excretion on pasture land is calculated as:

$$\text{TAN excretion pasture}_i = \text{N excretion pasture}_i \times \text{TAN fraction pasture}_i \quad (8.8)$$

In which

|                                    |  |
|------------------------------------|--|
| TAN excretion pasture <sub>i</sub> | : TAN excretion (kg N/animal/year) on pasture land for livestock category (i)      |
| N excretion pasture <sub>i</sub>   | : Total N excretion (kg N/animal/year) on pasture land for livestock category (i)  |
| TAN fraction pasture <sub>i</sub>  | : Fraction TAN in the total N excretion on pasture land for livestock category (i) |

The emission factor for grazing is calculated yearly, based on grass composition (year specific emission factor).

---

## 8.2.6 Ammonia emission from crop residues

For the calculation of the emission from crop residues the methodology and calculations of De Ruijter *et al.* (2013) are taken as the starting point:

$$\text{NH}_3 \text{ crop residues} = \sum \text{area grown} \times \text{N in residue} \times \text{EF NH}_3 \text{ crop residue} \times \text{contributing fraction} \times 17/14 \quad (8.9)$$

In which

|                                 |  |
|---------------------------------|--|
| NH <sub>3</sub> crop residues   | : Ammonia emission (kg NH <sub>3</sub> /year) from crop residues   |
| area grown                      | : Area per crop cultivated in ha   |
| N in residue                    | : N contained within the crop residues per crop in kg N/ha   |
| EF NH <sub>3</sub> crop residue | : Emission factor for crop residues in % of the N content  |
| contributing fraction           | : Fraction of the residues that contributes to ammonia emission (i.e. is not being incorporated into the soil in the first days after harvest) |
| 17/14                           | : Conversion factor from NH <sub>3</sub> -N to NH <sub>3</sub>   |

The percentage volatilization is based on N content of the residues and assumes full exposure of the crop residues to air, both in the amounts and over time (see Section 8.3.6). With the contributing residue fraction the part of the residues that are incorporated into the soils is being accounted for.

## 8.2.7 Ammonia emission during crop cultivation

Emissions from standing crops in the Netherlands have been calculated using the DEPAC resistance model (Van Zanten *et al.*, 2010). In this the exchange of ammonia between stomata of the plants, air layer directly above the crop and finally the atmosphere are modeled. Depending on ambient ammonia concentration and type of crop, emission or deposition will take place. These were determined on an hourly basis and aggregated over the growing season.

For the Netherlands a total emission of 1.5 Gg NH<sub>3</sub>-N was found using this method. This estimate has been adopted for the whole time-series, instead of calculating the emissions for each year separately. Reason is the high associated uncertainty, mainly originating from the stomatal compensations points needed for the calculation. It was deemed that using a calculation rule in which cultivated areas are taken into account, would represent a level of accuracy that cannot be attained at this point.

# 8.3 Emission factors

## 8.3.1 Emission factors for inorganic N-fertilizer application

Ammonia emission factors for inorganic N-fertilizer are based on Bouwman *et al.* (2002). In this review paper the results of 148 studies (1,667 ammonia measurements) from all over the world are used to quantify the effect of fertilizer type, crop, N addition, application method, temperature, soil characteristics (cation exchange capacity (CEC), pH, organic matter content) and location on ammonia emission. A regression analysis has been performed ( $R^2 = 28\%$ ) and based on this analysis a calculation model has been developed. For the Netherlands the following data are being used.

### **Crop**

In the calculation model a distinction is made between 'grassland' and 'upland crops'. The areas of grassland, cropland and maize have been taken from soil use maps. Grassland has a factor class value of -0.045 and cropland and maize are considered to be 'upland crops' (factor class value -0.158).

### **Fertilizer type**

Calculation has been performed for the fertilizer types in Bouwman *et al.* (2002), but not all inorganic N-fertilizer types used are mentioned. The emission factors have been calculated as follows:

- Ammonium sulphate nitrate; this fertilizer type contains both ammonium nitrate and ammonium sulphate. The emission factor is equal to the average emission factor of ammonium nitrate and ammonium sulphate;
- Nitrogen magnesium; this fertilizer type resembles calcium ammonium nitrate, but contains  $MgCO_3$  besides  $CaCO_3$  which however does not lead to a different emission factor;
- Chilean nitrate, calcium nitrate and potassium nitrate; these are fertilizer types that only contain nitrate N and no ammonium. As a result no  $NH_3$  emission from the soil can occur, and the emission factor is set to 0%;
- Mixed nitrogen fertilizer; this can be all kinds of fertilizer. The emission factor is set equal to that of the most used fertilizer types in the Netherlands;
- Nitrogen phosphate potassium magnesium fertilizers; these fertilizer types are comparable to nitrogen phosphate potassium fertilizer and emission factor is set to 2%;
- Ammonia water; this fertilizer type is comparable to liquid ammonia;
- Sulphur coated urea; the coating of this fertilizer type leads to lower emission than urea without coating (Oenema and Velthof, 1993). The emission factor is set to half that of urea.

### Application method

It is assumed that all inorganic N-fertilizers are surface applied (factor class value = -1.305).

### Soil pH

Bouwman *et al.* (2002) considers four pH-classes, where in the calculation for the Netherlands a distinction is made in lime containing and other soils. It is assumed that other soils have a pH < 7.3 and lime containing soils a pH > 7.3. For soils with a pH < 7.3 half is considered to have a pH lower than 5.5 and the other half a pH of 5.5-7.3 (factor class value becoming  $(-1.072 - 0.9333)/2 = -1.002$ ). For calcium rich soils pH is considered to be in the 7.3-8.5 range (factor class value = -0.608).

### Soil CEC

The CEC of soil types in the Netherlands varies strongly (from 60 for sea sand to more than 300 for peat and clayish peat; data of Bgg in Wageningen, the Netherlands) for 2007-2008; Arjan Reijneveld, Bgg, personal communication). Average CEC is  $70 \text{ mmol}_c/\text{kg}^{-1}$  for sand,  $180 \text{ mmol}_c/\text{kg}^{-1}$  for clay and loess and  $300 \text{ mmol}_c/\text{kg}^{-1}$  for peat and reclaimed peat soils. Based on the areas used it is calculated that the average CEC for grassland is  $146 \text{ mmol}_c/\text{kg}^{-1}$  and for cropland  $134 \text{ mmol}_c/\text{kg}^{-1}$ . Both for grassland and cropland a factor class value of 0.088 is therefore used.

### Climate

The climate in the Netherlands is temperate: factor class value = -0.408.

In Table 8.1 the resulting emission factors used to calculate  $NH_3$  emission from inorganic N-fertilizers are given. Default 2009 EMEP EFs are included for comparison.

Table 8.1

*Emission factors (in % of N) for inorganic N-fertilizer, derived using Bouwman et al., 2002 (default 2009 EMEP EFs are included for comparison)*

|  | EF used (in % of N) | Default 2009 EMEP EF (in % of N) |
|--|---------------------|----------------------------------|
| Ammonium nitrate   | 5.2                 | 0.7                              |
| Ammonium sulphate  | 11.3                | 4.1                              |
| Ammonium sulphate nitrate  | 8.2                 | 2.4                              |
| Chilean nitrate  | 0.0                 | 0.0                              |
| Diammonium phosphate   | 7.4                 | 4.1                              |
| Mixed nitrogen fertilizer  | 2.5                 | 0.7                              |
| Potassium nitrate  | 0.0                 | 0.0                              |
| Calcium ammonium nitrate   | 2.5                 | 0.7                              |
| Calcium nitrate  | 0.0                 | 0.0                              |
| Monoammonium phosphate   | 7.4                 | 4.1                              |
| Other nitrogen, phosphate and potassium fertilizers <sup>1</sup> | 4.5                 | 0.7                              |

|  | EF used (in % of N) | Default 2009 EMEP EF (in % of N) |
|--|---------------------|----------------------------------|
| Nitrogen phosphate potassium magnesium fertilizers | 2.5                 | 0.7                              |
| Nitrogen magnesium                                 | 2.5                 | 0.7                              |
| Urea   | 14.3                | 11.3                             |
| Liquid ammonia                                     | 2.3                 | 3.3                              |
| Sulphur coated urea                                | 7.1                 | 5.6                              |

<sup>1</sup> Including nitrogen phosphate and nitrogen potassium fertilizers.

### 8.3.2 Emission factors for manure application

Emission factors for manure application are based on measurements. The average emission figures based on all available observations per method including minimum and maximum values, and number of observations are presented in Table 8.2 (Huijsmans and Schils, 2009). The total emission per observation was estimated as the maximum of the emission curve, fitted by the measured emission figures in the period of 96 hours after application.

Table 8.2

*Average total emission (% of TAN applied) per application method of manure on grassland and cropland, based on all available observations (n)*

| Method                     | Average total emission (% of TAN) | Minimum | Maximum | n  |
|----------------------------|-----------------------------------|---------|---------|----|
| <i>Grassland</i>           |                                   |         |         |    |
| Surface spreading          | 74                                | 28      | 100     | 81 |
| Narrow-band                | 26                                | 9       | 52      | 29 |
| Deep injection             | 16                                | 1       | 63      | 89 |
| <i>Cropland</i>            |                                   |         |         |    |
| Surface spreading          | 69                                | 30      | 100     | 26 |
| Incorporation (direct)     | 22                                | 3       | 45      | 25 |
| Full coverage <sup>1</sup> | 2                                 | 1       | 3       | 7  |

<sup>1</sup> Full coverage: direct injection (one pass) or direct incorporation with the plow.

#### Statistical analysis of possible trends in time for the ammonia emission on grassland

Huijsmans and Schils (2009) assessed whether the ammonia emission on grassland systematically changed over the years since the measurements were performed (since 1988). Per technique a regression analysis was conducted, and it was analyzed whether observed trends can be explained by the circumstances under which measurements took place (manure and environmental variables). A factor "time since 1988" was added to the existing statistical models for influence of the circumstances, and analyzed for significance on emission speed after application.

The trend analysis revealed that measured emission rates after shallow injection on grassland had increased significantly since 1989 when experiments started. Because 1999 was the last year with many observations of the emission for shallow injection, the ammonia emission for this year and the following years was estimated to be 19%. For the reference (broadcast surface manure application) and narrow band application no effect of time since 1989 on the total ammonia emission was found.

#### Emission factors for other techniques

The CBS statistics include a manure application technique called slit coulter for which no emission data are available. As the slit coulter results in a manure placement intermediate between shallow injection and narrow band application, the EF for this technique is assessed as 22%, being the average of the EFs for shallow injection and narrow band application.

Depending on the method of manure incorporation, a certain reduction of NH<sub>3</sub> volatilization can be achieved on arable land. However, the reduction achieved by incorporation highly depends on the

time-lag between surface spreading and incorporation (Huijsmans and De Mol, 1999). The incorporation of the manure in a second pass always leads to a certain time lag. For this reason, the EFs for surface incorporation in two passes and ploughing in were estimated as 46% and 35%, respectively, being the average emission for surface spreading and direct incorporation. Presently, the application and incorporation of liquid manure in two passes is not allowed anymore in the Netherlands. Therefore, the EFs for arable land as shown in Table 8.3 are representative for current application methods i.e. spreading and incorporation in one operation.

**Table 8.3**

*Emission factors for ammonia (% of TAN applied) per application technique on grassland and on cropland, including increasing trend for deep injection*

| Land type/application technique          | EF (% of TAN) |           |           |           |              |
|--|---------------|-----------|-----------|-----------|--------------|
|  | 1990-1991     | 1992-1993 | 1994-1998 | 1999-2003 | From 2004 on |
| <i>Grassland</i>                         |               |           |           |           |              |
| Surface spreading                        | 74            | 74        | 74        | 74        | 74           |
| Narrow-band                              | 26            | 26        | 26        | 26        | 26           |
| Slit coulter <sup>1</sup>                | 18            | 18        | 20.5      | 22.5      | 22.5         |
| Shallow injection                        | 10            | 10        | 15        | 19        | 19           |
| <i>Cropland (uncropped)</i>              |               |           |           |           |              |
| Surface spreading                        | 64            | 69        | 69        | 69        | 69           |
| Incorporation in two passes <sup>2</sup> | 46            | 46        | 46        | 46        | 46           |
| Narrow-band                              | 36            | 36        | 36        | 36        | 36           |
| Slit coulter <sup>1</sup>                | 24.5          | 24.5      | 27.5      | 30        | 30           |
| Shallow injection                        | 13            | 13        | 19        | 24        | 24           |
| Incorporation (direct)                   | 22            | 22        | 22        | 22        | 22           |
| Full coverage                            | 2             | 2         | 2         | 2         | 2            |
| <i>Cropland (cropped)</i>                |               |           |           |           |              |
| Narrow-band                              | N/A           | N/A       | N/A       | N/A       | 36           |
| Shallow injection                        | N/A           | N/A       | N/A       | N/A       | 24           |

<sup>1</sup> For the emission factor for slit coulter the average of the emission factors for narrow-band and shallow injection is taken.

<sup>2</sup> For the emission factor for incorporation in two passes the average of the emission factors for surface spreading and direct incorporation is taken.

Source: Huijsmans and Schils (2009).

### 8.3.3 Emission factors for sewage sludge application

All sewage sludge is assumed to be applied to cropland, using shallow injection for the liquid part and incorporation in two passes for the solid part. The corresponding emission factors for manure application (Table 8.3) are used.

An exception is made for the first two years of the time series (1990 and 1991), where the emission factor for surface spreading is used for both liquid and solid sewage sludge. Reason is that before 1992 there was no obligation to incorporate sewage sludge into the soil directly, but within a few days of application causing the ammonia emission already having taken place.

### 8.3.4 Emission factors for other organic fertilizers (compost)

All compost is assumed to be applied to cropland, using surface spreading. The corresponding emission factor for manure application (Table 8.3) is used.

An exception is made for the first two years of the time series (1990 and 1991), where the emission factor is kept equal to that of later years. Reason is that in these years there was an obligation to incorporate surface spread manure into the soil on croplands. As a result the emission factor is set

---

lower for 1990 and 1991, but this requirement did not apply to compost. From 1992 onwards it is no longer allowed to surface spread liquid manure, and the obligation was lifted for other (solid) manures.

### 8.3.5 Emission factors for grazing

There are no recent measurements for NH<sub>3</sub> emission during grazing. From research of Bussink (1992, 1994) an emission factor in % of total N excretion was derived. From this work also an emission factor based on TAN can be derived since urine N excretion is reported next to total N excretion. Several adjustments to the dataset of Bussink (1992, 1994) were made and the emission factor for grazing (EF<sub>grazN</sub>) was corrected for:

- Inorganic N-fertilizer applied during the research of Bussink (1992, 1994);
- Changes over time in grazing systems used;
- Soil type.

Following each of these corrections is discussed briefly.

#### **Inorganic N-fertilizer application**

The emission factor for the inorganic N-fertilizer in the study of Bussink was 2% (calcium ammonium saltpeter on calcium rich clay). However there are reasons to assume that emissions at this specific study site would normally be lower:

- NH<sub>3</sub> emission from inorganic N-fertilizer is inhibited by the higher NH<sub>3</sub> concentration in the air from grazing (application took place around three days after grazing);
- Emission factors for inorganic N-fertilizers are derived from experiments where grass height was low compared to the research of Bussink (1992, 1994);
- Emission from inorganic N-fertilizer is slow and only a part of total NH<sub>3</sub> emission will have occurred during the measuring days;
- Measured NH<sub>3</sub> emission from calcium ammonium saltpeter at the same location in another year was 0.1% at 50 kg N/ha and 1% at 400 kg N/ha (Bussink, Wageningen UR, personal communication).

Also application of inorganic N-fertilizer took place in periods without grazing or NH<sub>3</sub> measurements. It is estimated that around 75% was applied when measurements were performed (Bussink, Wageningen UR, personal communication). The correction for inorganic N-fertilizer based on that amount, and an emission factor of 1% yields a corrected NH<sub>3</sub> emission for grazing between 6 and 38 kg N/ha.

#### **Grazing system**

The grazing systems in the Netherlands have shifted strongly towards systems with limited grazing in recent years (Aarts *et al.*, 2008; Van Bruggen and Faqiri, 2015). Bussink derived an emission factor in a situation with unlimited (day and night) grazing. Higher temperature, wind speed and global radiation during the day can lead to on average higher NH<sub>3</sub> emission from fresh urine patches. Furthermore during the night the grass is wet from dew and background concentrations of NH<sub>3</sub> are relatively high (little dilution).

This effect is also clearly seen in the measurements of Bussink. The average NH<sub>3</sub>-N flux over 24 hours was 38 g NH<sub>3</sub>-N per hour and 46 g NH<sub>3</sub>-N per hour in the period between 07:00 and 21:30h in case of restricted grazing (Bussink, 1992). Emission during the day is therefore a factor 1.20 higher, and this factor is used to derive the emission factor for systems with limited grazing from the emissions of Bussink (1992, 1994).

#### **Soil type**

The NH<sub>3</sub> emission also depends on the cation exchange capacity (CEC) of the soil (Bussink, 1994; Whitehead and Raistrick, 1993). With higher CEC, the soil can bind NH<sub>4</sub><sup>+</sup> more strongly and the risk of NH<sub>3</sub> emission reduces. The CEC correction calculated by Bussink (1996) is used:

$$\text{CEC correction} = (7.71 - 0.02793 \times (\text{CEC} - 280))/7.71 \quad (8.10)$$

Based on data of Blgg (Wageningen, the Netherlands) for 2007-2008 (Arjan Reijneveld, Blgg personal communication) the average CEC per soil type has been estimated. These are 70 mmol<sub>c</sub> kg<sup>-1</sup> for sand, 180 mmol<sub>c</sub> kg<sup>-1</sup> for clay and loess and 300 mmol<sub>c</sub> kg<sup>-1</sup> for peat and peat moss/cover-sand soils. Resulting correction factors for these soil types are 1.8, 1.4 and 0.9 respectively.

After correction for inorganic N-fertilizer use and grazing system, emission factors based on TAN vary between 4.0 and 11.7 depending on soil type. Using the national soil use map of the Netherlands (LGN) it shows that 15% of the grassland is on peat, 47% on sand and 39% on clay and loess. Based on these areas and the CEC correction, a weighted emission factor in % of TAN is calculated (Bussink, 1996):

$$\begin{aligned} \text{EF NH}_3 \text{ grazing} &= 2.6\%, \text{ with } N_{\text{ration}_{\text{WUM}}} < 25 \text{ g N per kg DM} \\ \text{EF NH}_3 \text{ grazing} &= 1.98 \times 10^{-5} * (N_{\text{ration}_{\text{WUM}}})^{3.664}, \text{ with } N_{\text{ration}_{\text{WUM}}} \geq 25 \text{ g N per kg DM} \end{aligned} \quad (8.11)$$

In which

EF NH<sub>3</sub> grazing : Emission factor (% of TAN) for grazing

N<sub>ration<sub>WUM</sub></sub> : Average N content of the ration during the grazing season according to the WUM (g N per kg dry matter).

High N rates in feed result in high N excretion and high TAN values, which lead to high NH<sub>3</sub> emission. In the Netherlands no measurement data are available for NH<sub>3</sub> emission from grazing by other grazing animal species (other cattle, horses, ponies and sheep). It is assumed that these will be equal to dairy cows. As a result, the formula for dairy cattle is also used for other grazing animals.

### 8.3.6 Emission factors for crop residues

To calculate the percentage of N that is emitted as NH<sub>3</sub> from crop residues, a regression model has been derived from literature describing the relationship between ammonia emission and the N content of residues (De Ruijter and Huijsmans, 2012):

$$\text{EF NH}_3 \text{ crop residue} = 0.40 \times \text{N content} - 5.08 \quad (8.12)$$

In which

N content : N contained in above-ground crop residues (g/kg dry matter) per crop

Based on the regression equation, no emission occurs if the N content is below 12.7 g/kg. The model assumes complete exposure to air of all residues, for a prolonged period of time.

### 8.3.7 Emission factors for crop cultivation

For ammonia emissions from standing crops, a fixed estimate is reported based on De Ruijter *et al.* (2013). Therefore no emission factors are needed for the calculations.

## 8.4 Activity data

Annex 1 presents an overview of the animal (sub-)categories being distinguished in the Agricultural Census. This categorization is also used within the NEMA calculations, and results are then grouped towards reporting categories as indicated.

PVE (2005) estimated the Netherlands has 300,000 privately owned horses. This number is added to the result of the Agricultural Census, and resulting emissions are attributed to the 'Other' category.

---

#### 8.4.1 Data needed for calculation of emission from fertilizer application

The usage of the different types of inorganic N-fertilizers is taken from the synthetic fertilizer statistics of LEI Wageningen UR. Amount of rinsing liquid produced by air scrubbers, as calculated by NEMA, is also taken into consideration.

#### 8.4.2 Data needed for calculation of emission from manure application

The amount of TAN in manure that is applied to the soil is calculated from the urine N excretion and mineralization of organic N in animal houses and the gaseous N losses occurring in animal houses and during manure storage. Based on Statistics Netherlands (CBS) statistics, data from the Ministry of Economic Affairs (Netherlands Enterprise Agency) and calculations of the manure market these amounts are corrected for manure processing, export of manure and import of manure.

The amounts of manure applied to grassland and cropland are based on the results of the calculations performed in the perspective of monitoring the manure market (Luesink *et al.*, 2008 and De Koeijer *et al.*, 2012; based on the Farm Accountancy Data Network (FADN; or BIN in Dutch) of LEI Wageningen UR and on the data about manure transport of the Netherlands Enterprise Agency). If there are no data on the division of manure over grassland and cropland, then based on loss- or usage norms an estimation is made on the division of manure on grassland and cropland based on acceptance grade in various regions (filling in usage norms).

For the implementation grade of application techniques the results of the Agricultural Census are used. In the Agricultural Census of 2010 the kind of manure application techniques on grassland and on cropland were questioned for the last time. For grassland there was the choice of injection, shallow injection, slit coulter, narrow-band application and other. It is assumed that a part of the manure is surface spread (Van Bruggen *et al.*, 2015). For cropland there was the choice of injection, narrow-band application, incorporation in 1 pass, incorporation in 2 passes and other. It is assumed that a part of the manure is surface spread (Van Bruggen *et al.*, 2015). It deserves recommendation to gather closer information on the implementation of the different techniques used in practice (Table 8.3). More detailed information on the calculation of emissions from manure application can be found in Kruseman *et al.* (2012).

#### 8.4.3 Data needed for calculation of emission from sewage sludge application

Amounts of sewage sludge applied to agricultural soils are available from Statistics Netherlands (CBS). The percentage TAN in the sludge is calculated from German data on N and TAN contents of liquid and solid sewage sludge (Landwirtschaftliches Wochenblatt, 2007).

#### 8.4.4 Data needed for calculation of emission from other organic fertilizers (compost)

Amounts of organic (household) waste and green refuse compost are available from Statistics Netherlands (CBS). The percentage TAN is taken from the Arable fertilization advice (De Haan and Van Geel, 2013; Bemestingsadvies akkerbouw, [www.kennisakker.nl](http://www.kennisakker.nl)).

#### 8.4.5 Data needed for calculation of emission from grazing

##### **Animal numbers**

Annex 1 presents an overview of the animal (sub-)categories being distinguished in the Agricultural Census. This categorization is also used within the NEMA calculations, and results are then grouped towards reporting categories as indicated.

PVE (2005) estimated the Netherlands has 300,000 privately owned horses. This number is added to the result of the Agricultural Census, and resulting emissions are attributed to the 'Other' category.

## N excretion on pasture land

For each grazing animal category distinguished, the N excretion on pasture land is determined on a yearly basis by the Working group on Uniformity of calculations of Manure and mineral data (WUM).

## Percentage TAN in pasture manure

The percentage of the N excretion that is TAN, is determined on a yearly basis by the Working group on Uniformity of calculations of Manure and mineral data (WUM) for each grazing animal category.

### 8.4.6 Data needed for calculation of emission from crop residues

Areas of cultivated crops are derived from the Agricultural Census. For the N contents of crop residues for grass, data of the Working group on Uniformity of calculations of Manure and mineral data (WUM) have been used. In the other crops data available from De Ruijter *et al.* (2013) was used for the N content of the crop residues.

Data on grassland renovation were obtained from Statistics Netherlands (CBS) and LEI Wageningen UR. Crop residues also occur in the cutting, drying and collection of grass for the production of silage or hay and an average amount of 1,000 kg dry matter/ha/year is assumed. Pasture topping also generates crop residues but is not considered separately as it is accounted for in the emission factor for grazing (De Ruijter *et al.*, 2013).

### 8.4.7 Data needed for calculation of emission from crop cultivation

For ammonia emissions from standing crops, a fixed estimate is reported based on Van Zanten *et al.* (2010). Therefore no activity data is needed for the calculations.

## 8.5 Uncertainty and quality

The uncertainty estimate<sub>total</sub> concerns the root of the sum of uncertainty in the data sources used (AD<sub>unc</sub>) in the square and the uncertainty of the emission factors (EF<sub>unc</sub>) in the square. The extent of the total uncertainty is here primarily determined by the greatest AD or EF uncertainty.

$$\text{Uncertainty estimate}_{\text{total}} = \sqrt{(\text{AD}_{\text{unc}}^2 + \text{EF}_{\text{unc}}^2)} \quad (8.13)$$

The uncertainty estimates concerning the data sources (AD) and emission factors (EF) used, and the total uncertainty estimate, are listed in the following Table 8.4.

Table 8.4

*Uncertainty estimates for NH<sub>3</sub> from NFR category 3D agricultural soils*

| EMEP  | Category   | AD <sub>unc</sub> | EF <sub>unc</sub> | Uncertainty estimate <sub>total</sub> |
|-------|--|-------------------|-------------------|---------------------------------------|
| 3Da2a | Animal manure applied to soils                           | 2-10              | 31-149            | 31                                    |
| 3Da1  | Inorganic N-fertilizers (includes also urea application) | 12                | 10                | 16                                    |

The uncertainty of NH<sub>3</sub> emissions as a result of crop production and agricultural soils is based on expert judgement. Uncertainty in activity data (= animal numbers) is 2-10% depending on animal category (CBS, 2012) and uncertainty in the NH<sub>3</sub> EF for animal manure applied to soils, based on expert judgements, was estimated to be 31-149%. For inorganic N-fertilizers this is respectively 12 and 10 percent, for total activity and (average) emission factor.

A detailed overview of quality assurance and quality control is given in Annex 12. In this annex also some outlines on the verification of data are presented.

---

# 9 NO<sub>x</sub> emissions from crop production and agricultural soils (NFR category 3D)

## 9.1 Scope and definition

The NFR source category 3D Crop production and agricultural soils consists of:

- 3Da1 Inorganic N-fertilizers (includes also urea application)
- 3Da2a Livestock manure applied to soils
- 3Da2b Sewage sludge applied to soils
- 3Da2c Other organic fertilizers applied to soils (including compost)
- 3Da3 Urine and dung deposited by grazing animals
- 3Da4 Crop residues applied to soils

No emissions of NO<sub>x</sub> occur in the source categories 3Db Indirect emissions from managed soils, 3Dc Farm-level agricultural operations including storage, handling and transport of agricultural products, 3Dd Off-farm storage, handling and transport of bulk agricultural products, 3De Cultivated crops and 3Df Use of pesticides. Since field burning is prohibited by law in the Netherlands, also no emissions occur in category 3F Field burning of agricultural residues. Lastly it was chosen not to report emissions under the 3I Agriculture other category.

Although emissions are reported as nitrogen monoxide by NEMA, it is referred to as NO<sub>x</sub> in this report to prevent confusion with the notation key NO.

## 9.2 Calculation method

Total NO<sub>x</sub> emissions from crop production and agricultural soils are calculated as:

$$\text{NO}_x \text{ emission } 3D = \sum \text{EF} \times \text{supply source}_m \times 30/14 \quad (9.1)$$

NO<sub>x</sub> emission 3D : Nitrogen oxides emission (kg NO<sub>x</sub>/year, expressed as nitrogen monoxide) for all defined supply sources (m)  
supply source<sub>m</sub> : Amount of N (kg N/year) for supply source (m)  
30/14 : Conversion factor from NO<sub>x</sub>-N to NO<sub>x</sub>, expressed as nitrogen monoxide

## 9.3 Emission factors

NO<sub>x</sub> emissions from N input to the soil are calculated using the default EMEP emission factor of 0.012 kg NO<sub>x</sub>-N/kg N input.

## 9.4 Activity data

### *Inorganic N-fertilizers*

The usage of the different types of inorganic N-fertilizers is taken from the synthetic fertilizer statistics of the Agricultural Economics Institute of Wageningen UR (LEI Wageningen UR).

---

### **Livestock manure applied to soils**

The amount of N that is applied with manure to the soil is calculated from the urine N excretion and mineralization of organic N in animal houses and the gaseous N losses occurring in animal houses and manure storages. Based on Statistics Netherlands (CBS) statistics, data from the Ministry of Economic Affairs-Netherlands Enterprise Agency and calculations of the manure market these amounts are corrected for manure processing, export of manure and import of manure.

### **Sewage sludge applied to soils**

The amount of sewage sludge applied to agricultural soils is calculated by CBS and published via Statline.

### **Other organic fertilizers applied to soils (including compost)**

The amount of compost applied to agricultural soils is calculated by CBS and published via Statline.

### **Urine and dung deposited by grazing animals**

Part of the livestock manure is produced on pasture land during grazing. The amount of nitrogen per animal is calculated by the WUM (Working group on Uniformity of calculations of Manure and mineral data) and is available from the CBS website, [www.cbs.nl](http://www.cbs.nl). Statistics concerning the animal populations are also available on the CBS site.

### **Crop residues applied to soils**

Conform the IPCC calculation rules this includes all arable and outdoor horticultural crops (e.g. not from greenhouse farming). All crops that fall under both these two categories are included in the Agricultural Census, available via [www.cbs.nl](http://www.cbs.nl), and are included in the calculations for nitrogen monoxide emissions. In addition, a fixed country-specific value in kg N per hectare is used for the nitrogen content of the above-ground crop residues. Finally, the calculations take account of the fact that sometimes part of the above-ground crop residues are removed from the field and thus do not contribute to laughing gas emissions. Country-specific values are used for these removals, as reported in Van der Hoek *et al.* (2007).

The areas used for these crops are taken from the annual Agricultural Census.

## **9.5 Uncertainty and quality**

The uncertainty estimate<sub>total</sub> concerns the root of the sum of uncertainty in the data sources used ( $AD_{unc}$ ) in the square and the uncertainty of the emission factors ( $EF_{unc}$ ) in the square. The extent of the total uncertainty is here primarily determined by the greatest AD or EF uncertainty.

$$\text{Uncertainty estimate}_{\text{total}} = \sqrt{(AD_{unc}^2 + EF_{unc}^2)} \quad (9.2)$$

The uncertainty of  $NO_x$  emissions as a result of crop production and agricultural soils is based on expert judgement. Uncertainty in activity data is 5-12% depending on supply source and uncertainty in the  $NO_x$  EF for agricultural soils is taken from the EMEP Guidebook (EEA, 2009).

A detailed overview of quality assurance and quality control is given in Annex 12. In this annex also some outlines on the verification of data are presented.

---

# 10 N<sub>2</sub>O emissions from crop production and agricultural soils (CRF sector 3D)

## 10.1 Scope and definition

Nitrous oxide (N<sub>2</sub>O) can be emitted from agricultural soils either directly or indirectly. Direct emissions occur after the application of inorganic N-fertilizer or manure, and during grazing following (de-) nitrification. These activities also lead to emissions of ammonia (NH<sub>3</sub>) and nitrogen monoxide (NO<sub>x</sub>), as described in Chapters 8 and 9 respectively. Deposition of nitrogen (from emitted NH<sub>3</sub> and NO<sub>x</sub>) and leaching or run-off from agricultural soils provide nitrogen compounds to land and aquatic systems, from which N<sub>2</sub>O emissions again take place. Together called indirect emissions, they are attributed to agriculture whether or not emission occurs on agricultural land or even within the country, as agricultural activities form the initial source.

### 10.1.1 Direct N<sub>2</sub>O emissions from managed soils

This chapter describes the methodology and working processes for determining direct emissions of N<sub>2</sub>O from the soil as a result of agricultural activities in the Netherlands. This concerns the Common Reporting Format (CRF) source category 3Da Direct N<sub>2</sub>O emissions from managed soils, subdivided into:

- 3Da1 Inorganic N fertilizers
- 3Da2 Organic N fertilizers (with further subdivision into animal manure, sewage sludge and other organic fertilizers applied to soils)
- 3Da3 Urine and dung deposited by grazing animals
- 3Da4 Crop residues
- 3Da6 Cultivation of organic soils (i.e. histosols)

In source category 3Da5 Mineralization/immobilization associated with loss/gain of soil organic matter, only emissions from cropland remaining cropland are to be reported. According to the methodology used for the Land Use, Land Use Change and Forestry (LULUCF) sector in the Netherlands, no emissions occur in this case (Arets *et al.*, 2015). Also the Netherlands has not allocated emissions to source category 3Da7 Other.

Nitrous oxide is formed in the soil during the microbiological processes of nitrification and denitrification. Nitrification concerns the process whereby ammonia (NH<sub>4</sub><sup>+</sup>) under aerobic (oxygen-rich) conditions is converted into nitrate by bacteria. In liquid manure oxygen is the limiting factor for nitrification. Nitrous oxide can be formed as a by-product, particularly when the nitrification process is delayed through lack of oxygen. No organic substances are required for nitrification. Denitrification is the microbiological transformation of NO<sub>3</sub><sup>-</sup> under anaerobic (low-oxygen) conditions into the gaseous nitrogen compound N<sub>2</sub>, with N<sub>2</sub>O as a by-product. Organic substances are used as energy source. Organic soils have higher emissions of nitrous oxide than mineral soils.

### 10.1.2 Indirect N<sub>2</sub>O emissions from managed soils

This chapter also describes the methodology and working processes for determining the indirect N<sub>2</sub>O emissions from the soil, as a result of agricultural activities in the Netherlands. This concerns CRF source category: 3Db Indirect N<sub>2</sub>O emissions from managed soils.

The IPCC Guidelines (2006) give separate estimates of the direct and indirect emissions of nitrous oxide from the agricultural sector. *Direct* emissions occur in the agricultural system, primarily as a result of the application of inorganic N-fertilizers and livestock manure. *Indirect* emissions of nitrous oxide concern the formation of N<sub>2</sub>O in soils and aquatic systems as a result of nitrogen losses from the soil to air and water.

---

The IPCC differentiates between two sources of indirect nitrous oxide emissions.

- Indirect nitrous oxide emissions after atmospheric depositions of nitrogen compounds that have evaporated in the form of ammonia and nitrogen oxides from animal houses and manure storage (attributed to manure management, see Chapter 6); from inorganic N-fertilizer, livestock manure application, grazing, sewage sludge and compost (attributed to agricultural soils, this chapter).
- Indirect nitrous oxide emissions from aquatic systems through nitrogen (especially nitrate) leaching and runoff from agricultural soils. Nitrate undergoes denitrification in groundwater or surface water, which creates nitrous oxide.

## 10.2 Calculation method

Total nitrous oxide emissions from managed soils are calculated as:

$$N_2O \text{ emissions } 3D = N_2O \text{ emission direct} + N_2O \text{ emission indirect} \quad (10.1)$$

In which

$N_2O$  emissions 3D : Nitrous oxide emissions (kg  $N_2O$ /year) from CRF source category 3D agricultural soils and crop production

$N_2O$  emission direct : Direct  $N_2O$  emissions from agricultural soils and crop production

$N_2O$  emission indirect : Indirect  $N_2O$  emissions from agricultural soils and crop production

### 10.2.1 Direct $N_2O$ emissions from managed soils

Direct nitrous oxide emissions from agricultural soils are calculated by multiplying the amount of nitrogen per supply source by country-specific emission factors. Because the ratio between mineral and organic soils is relatively constant, the emission factors are a weighted mean of all soil types. The total  $N_2O$  emissions from all supply sources are then calculated by adding up the  $N_2O$  emissions per supply source. For detailed information, please refer to the background document (Van der Hoek *et al.*, 2007).

$$N_2O \text{ emission direct} = \sum \text{supply source}_m \times EF_m \times 44/28 \quad (10.2)$$

In which

supply source<sub>m</sub> : Amount of N for the defined supply source (m) (kg N)

$EF_m$  : Emission factor for the defined supply source (m) in kg  $N_2O$ -N/kg N in supply source

44/28 : Conversion factor from  $N_2O$ -N to  $N_2O$

The aforementioned formula differentiates between the following N supply sources (m):

1. Gross application of N from inorganic N-fertilizer, i.e. not reduced by the  $NH_3$  and  $NO_x$  emission when applying inorganic N-fertilizer.
2. Gross application of N from livestock manure, i.e. not reduced by the  $NH_3$  and  $NO_x$  emission when applying livestock manure, but minus emissions from animal houses and manure storages together with net export (export - import).
3. Gross N to the soil through grazing domestic agricultural animals, i.e. not reduced by the  $NH_3$  and  $NO_x$  emission when grazing.
4. Remaining crop residues.
5. Agricultural use of organic soils.
6. Sewage sludge.
7. Compost.

These emissions are being reported under their respective Common Reporting Format (CRF) categories, with 3Da2 Organic N fertilizers consisting of the sub-sources livestock manure, sewage sludge and compost.

The NEMA model is used to determine soil load (in kg N) caused by the application of inorganic N-fertilizer, livestock manure and grazing (Velthof *et al.*, 2012).

---

### Comparison to IPCC methodology

The methodology described above conforms to the IPCC method, as described in the IPCC Guidelines (IPCC, 2006).

Determining the extent of the NH<sub>3</sub> and NO<sub>x</sub> emissions from animal houses and storage is carried out using country-specific data at Tier 2 or 3 level. Determining the N<sub>2</sub>O emissions is carried out using a Tier 1b/2 analysis. The use of artificial fertilizers and livestock manure is split into two types of manure application techniques, each has its own country-specific emission factor (see Annex 11 and Velthof and Mosquera, 2011).

#### 10.2.2 Indirect N<sub>2</sub>O emissions from managed soils

Indirect nitrous oxide emissions from agricultural soils are calculated by multiplying the amount of nitrogen per supply source by the default 2006 IPCC emission factors. The total N<sub>2</sub>O emission of all supply sources is then calculated by adding up the N<sub>2</sub>O emissions per supply source. Detailed information can be found in the background document (Van der Hoek *et al.*, 2007).

$$\text{N}_2\text{O emission indirect} = \sum \text{supply source}_m \times \text{EF}_m \times 44/28 \quad (10.3)$$

In which

supply source<sub>m</sub> : Amount of N for supply source (m)

EF<sub>m</sub> : Emission factor (kg N<sub>2</sub>O-N/kg N supply) for supply source (m)

44/28 : Conversion factor from N<sub>2</sub>O-N to N<sub>2</sub>O

The aforementioned formula differentiates between the following supply sources for agricultural soils:

1. Deposition of ammonia and nitric oxide released during grazing and application of inorganic N-fertilizer, livestock manure, sewage sludge and compost to agricultural soil.
2. Leaching and runoff of nitrogen added to agricultural soil, in which N mineralization through the cultivation of organic soils and crop residues are also considered to be supply sources.

### Comparison to IPCC methodology

The aforementioned method is similar to the IPCC method as described in the IPCC Guidelines (IPCC, 2006).

The IPCC also differentiates between two other supply sources.

- N<sub>2</sub>O formation in the atmosphere from ammonia emissions. The IPCC gives no calculation method for this source, therefore the nitrous oxide emissions created by ammonia in the atmosphere are not included here.
- Discharging effluent from sewage treatment plants into surface water. The nitrous oxide emissions created from discharging effluent into surface water are not included in the agricultural sector, but in the CRF (Common Reporting Format) Category 6B.

Determining the extent of the various supply sources is carried out using country-specific data at Tier 2 or 3 level. The N<sub>2</sub>O emissions are determined via a Tier 1 analysis. Default IPCC emission factors are used.

Additional information on the emission factors is included in Section 10.3.2.

## 10.3 Emission factors

### 10.3.1 Direct N<sub>2</sub>O emissions from managed soils

The total direct emissions of nitrous oxide from agricultural soils are calculated by multiplying the amount of nitrogen per supply source by a fixed country-specific emission factor, and then aggregate this over all supply sources (Van der Hoek *et al.*, 2007). Table 10.1 provides an overview of the emission factors used.

**Table 10.1**

*Emission factors for direct nitrous oxide emission from agricultural soils*

| Supply source                             | EF (kg N <sub>2</sub> O-N per kg N supply ) |         | Reference |
|---|---|---------|-----------|
|   | Default IPCC                                | EF used |           |
| <i>Inorganic N-fertilizer application</i> | 0.01  | 0.013   | 1         |
| <i>Manure application</i>                 | 0.01  |         |           |
| - above ground (surface spreading)        |   | 0.004   | 1         |
| - low ammonia emission application        |   | 0.009   | 1         |
| <i>Sewage sludge</i>                      | 0.01  |         | 2         |
| - above ground (surface spreading)        |   | 0.004   |           |
| - low ammonia emission application        |   | 0.009   |           |
| <i>Compost</i>                            | 0.01  | 0.004   |           |
| <i>Pasture manure livestock</i>           |   | 0.033   | 1         |
| - cattle, pigs and poultry                | 0.02  |         |           |
| - sheep and other animals                 | 0.01  |         |           |
| Crop residues                             | 0.01  | 0.01    | 2         |
| Cultivation of organic soils              | -   | 0.02    | 2, 3      |

References: 1 = Velthof *et al.* (2010); Velthof and Mosquera (2011); Van Schijndel and Van der Sluis (2011), see Annex 11; 2 = Van der Hoek *et al.* (2007); 3 = Kuikman *et al.* (2005).

In general, organic soils have a higher emission factor than mineral soils. Because the ratio between the two is relatively constant weighted means are used. Furthermore, the emission factor for low emission manure application is twice that of the emission factor for above-ground manure application.

The following section provides further information, per supply source, on the emission factors used.

**Inorganic N-fertilizer application**

An emission factor of 0.013 is used for inorganic N-fertilizer application. This is the weighted mean of various inorganic N-fertilizer and soil types.

**Livestock manure application**

An emission factor of 0.004 kg N<sub>2</sub>O-N per kg net applied N is applied for above-ground application of livestock manure. This factor is 0.009 for low emission manure application. Both figures are weighted means for mineral and organic soils. The higher emission factor for low emission manure application methods is caused by the larger amount of N available for nitrification/denitrification using this method.

**Grazing of livestock**

For grazing, an emission factor of 0.033 kg N<sub>2</sub>O-N per kg net produced N is used. This is a weighted mean over soil types.

**Remaining crop residues**

For crop residues an emission factor of 0.01 kg N<sub>2</sub>O-N per kg N is used for the crop residues remaining on mineral soils. This value is estimated from Dutch research studies carried out in the first half of the 1990s (Kroeze, 1994). Arable farming and outdoor horticulture hardly ever occur in organic soils.

**Agricultural use of organic soils**

Average mineralization is 233.5 kg N per hectare peat soil and 204.5 kg N per hectare other organic soil (Kuikman *et al.*, 2005). Using an emission factor of 0.02 (largely taken from Dutch research projects conducted in the first half of the 1990s and reported in Kroeze, 1994), the nitrous oxide emission of histosols amounts to 4.67 kg N<sub>2</sub>O-N per hectare peat soil and 4.09 kg N<sub>2</sub>O-N per hectare other organic soils.

## Sewage sludge

For sewage sludge the emission factors of manure application are used. These are 0.004 kg N<sub>2</sub>O-N per kg N for surface application and 0.009 kg N<sub>2</sub>O-N for low ammonia emission application.

## Compost

All compost is assumed to be surface applied, and has an emission factor of 0.004 kg N<sub>2</sub>O-N per kg N applied.

### 10.3.2 Indirect N<sub>2</sub>O emissions from managed soils

With respect to *leaching and runoff* of the nitrogen added to soil, the emission factor concerns that part of the nitrogen that is leached and runoff, the so-called FRAC<sub>leach</sub>. A country-specific value is applied because of the relatively high groundwater tables in the Netherlands (Velthof and Mosquera, 2011).

The total indirect nitrous oxide emissions from agricultural soils is calculated by multiplying the amount of nitrogen per supply source by the following emission factors of Table 10.2 and then aggregating this over all supply sources (Van der Hoek *et al.*, 2007).

Table 10.2

FRAC<sub>leach</sub> and nitrous oxide emission factors for indirect nitrous oxide emissions from agricultural soil.

| Supply source   | Factor   |
|---|--|
| Depositions of NO <sub>x</sub> and ammonia emissions from agricultural soil |  |
| - nitrous oxide emission factor   | 0.01 kg N <sub>2</sub> O-N per kg N supply           |
| Leaching and runoff from agricultural soil                                  |  |
| - FRAC <sub>leach</sub>   | 0.15 kg N per kg N to soil (1990-1991)               |
|   | 0.14 kg N per kg N to soil (1992-1997)               |
|   | 0.13 kg N per kg N to soil (1998-present)            |
| - nitrous oxide emission factor   | 0.0075 kg N <sub>2</sub> O-N per kg N leached/runoff |

Source: Van der Hoek *et al.*, 2007; Velthof and Mosquera, 2011.

The following section provides additional information on the emission factors used.

### Depositions of ammonia and NO<sub>x</sub> on the soil

The lack of measurement data in the Netherlands means that IPCC default emission factors were chosen when calculating the indirect emissions of nitrous oxide (Denier van der Gon *et al.*, 2004; Van der Hoek *et al.*, 2007).

### Leaching and runoff of nitrogen added to the soil

The following calculation rule is used to calculate the nitrous oxide emissions for this supply source.

$$N_2O \text{ leaching and runoff} = \sum \text{supply source} \times \text{FRAC}_{\text{leach}} \times \text{EF} \times 44/28 \quad (10.4)$$

In which

|                       |   |
|-----------------------|---|
| supply source         | : Amount of N in the supply source (kg)                         |
| FRAC <sub>leach</sub> | : Fraction of the nitrogen that is leaching and running off     |
| EF                    | : Emission factor in kg N <sub>2</sub> O-N/kg N supply          |
| 44/28                 | : Conversion factor from N <sub>2</sub> O-N to N <sub>2</sub> O |

The amount of nitrogen refers to the total amount of inorganic N-fertilizer and the total amount of livestock manure, minus the net export of manure to other countries. The emission factor used is the IPCC default and the FRAC<sub>leach</sub> is country-specific. Further background information on the FRAC<sub>leach</sub> values can be found in Velthof and Mosquera, 2011. Further information concerning the nitrous oxide emission factor of 0.0075 can be found in the 2006 IPCC Guidelines (footnote on p. 11.24).

---

## 10.4 Activity data

### 10.4.1 Direct N<sub>2</sub>O emissions from managed soils

The following information is required in order to carry out the calculation using the method described in section 10.1.1. Furthermore, the necessary emission factors are discussed in Section 10.2.1 of this chapter.

#### **Mineral and organic soils**

As the ratio between mineral and organic soils is relatively constant, weighted emission factors are used for the calculations (Van Schijndel and Van der Sluis, 2011; Annex 11).

#### **Gross amount of nitrogen in inorganic N-fertilizer applied to soil**

Figures relating to the total gross amount of nitrogen in fertilizer are gathered annually by the LEI (Dutch Agricultural Economic Institute, see also [www.lei.wur.nl](http://www.lei.wur.nl)). The NEMA model calculates emissions of NH<sub>3</sub>, N<sub>2</sub>O and NO<sub>x</sub> from these fertilizers, taking the diversity of inorganic N-fertilizer types into account.

#### **Gross amount of nitrogen in livestock manure applied to soil**

The gross amount of nitrogen in livestock manure from animal houses and outside manure storages is calculated using the method described in Section 4.2. This is also the gross amount of nitrogen in livestock manure used on agricultural soils, after subtracting emissions from animal housing and outside storage plus the N in net exported manure (i.e. export - import).

Emissions of NH<sub>3</sub>, N<sub>2</sub>O and NO<sub>x</sub> resulting from the application of livestock manure on agricultural soils are calculated with the NEMA model. The calculations of the N<sub>2</sub>O emissions distinguish between above-ground and low-emission application techniques.

#### **Gross amount of nitrogen in manure produced on pasture land**

Part of the livestock manure is produced on pasture land. The amount of nitrogen per animal is calculated by the WUM (Working group on Uniformity of calculations of Manure and mineral data) and is available from [www.cbs.nl](http://www.cbs.nl). Statistics concerning the animal populations are also available on the CBS site.

#### **Amount of nitrogen in crop residues**

Conform the IPCC calculation rules this includes all arable and outdoor horticultural crops (e.g. not from greenhouse farming). All crops that fall under both these two categories are included in the Agricultural Census, available via [www.cbs.nl](http://www.cbs.nl), and are included in the calculations for nitrous oxide emissions. In addition, a fixed country-specific value in kg N per hectare is used for the nitrogen content of the above- and below ground crop residues. Finally, the calculations take account of the fact that sometimes part of the above-ground crop residues are removed from the field and thus do not contribute to nitrous oxide emissions. Country-specific values are used for these removals, as reported in Van der Hoek *et al.* (2007).

The areas used for these crops are taken from the annual Agricultural Census, which includes all agricultural companies with their headquarters in the Netherlands and which are larger than, or equal to, three Netherlands size units (nge, until 2009) or 3,000 Standard Output (SO, from 2010).

#### **Cultivation of organic soils**

Nitrous oxide emissions are determined by multiplying the area of peat and other organic soils by specific Netherlands emission factors. The extent of the areas cultivated is estimated from the land use maps of the Land Use, Land Use Change and Forestry (LULUCF) sector. Maps are available for the base year 1990, 2004, 2009 and 2013. Between these years interpolation takes place. An overview of the resulting areas can be found in Annex 18 to Van Bruggen *et al.* (2015).

---

## Sewage sludge

The amount of sewage sludge applied to agricultural soils is calculated by the CBS and published via Statline.

## Compost

The amounts of organic waste and green refuse compost applied to agricultural soils or used outside agriculture, is calculated by the CBS and published via Statline.

### 10.4.2 Indirect N<sub>2</sub>O emissions from managed soils

To carry out the calculation following the method described in Section 10.1.2 of this chapter, below mentioned data sources are needed. In addition, the emission factors discussed in Section 10.2.2 are used.

#### Depositions of ammonia and nitric oxide on the soil

Although the term 'deposition' is used here, it follows from the IPCC Guidelines that this refers not to ammonia depositions, but to the total ammonia and nitric oxide emissions by the agricultural sector in the Netherlands. This primarily concerns the total depositions of all NH<sub>3</sub> and NO<sub>x</sub> emitted by the Netherlands agricultural sector, whatever the geographical location of these depositions (thus also outside the country's borders).

The extent of the NH<sub>3</sub> emissions from inorganic N-fertilizer and livestock manure application and during grazing, are calculated within the National Emissions Model for Agriculture (NEMA) using country specific emission factors. For NO<sub>x</sub> emissions EMEP default emission factors for the application of inorganic N-fertilizer, application of livestock manure and grazing are applied.

#### Leaching and runoff of nitrogen added to the soil

The IPCC Guidelines clearly indicate that the gross supply refers to nitrogen in inorganic N-fertilizer and livestock manure, thus without deducting NH<sub>3</sub> and NO<sub>x</sub> evaporation from animal houses, manure storage, grazing and use of manure. The reason for this is that the leaching and runoff is then the result of (subsequent) depositions of NH<sub>3</sub> and NO<sub>x</sub> which are included immediately and do not need to be determined separately. Any manure that is net exported (export – import) to other countries is deducted from the above.

The annual figures showing the amount of nitrogen produced in livestock manure are yearly calculated by the Working group on Uniformity of calculations of Manure and mineral data (WUM) and published via [www.cbs.nl](http://www.cbs.nl). This applies to both animal house and pasture manure. The nitrogen in exported manure is also determined annually by CBS.

A country-specific value of 15 to 13% is applied for the part of nitrogen introduced to the soil that is leached (the FRAC<sub>leach</sub> in IPCC definitions) and subsequently forms a source of indirect N<sub>2</sub>O emission (see Table 10.2).

## 10.5 Uncertainty and quality

A Tier 1 uncertainty analysis is implemented every year before the NIR is submitted by the ER, based on the greenhouse gas inventory and in compliance with IPCC Guidelines. The assumptions used and the results thereof are described in an annex to the NIR. In addition to this, where included in the QA/QC-programme for the relevant period, extra analyses are implemented regularly in specific situations, which include any updating of the Tier 2 uncertainty analyses.

The Tier 2 uncertainty assessment was last updated in 2009. This assessment showed that a Tier 1 uncertainty assessment is sufficiently reliable and that Tier 2 uncertainty assessments need only be implemented at periodic intervals of around 5 years, unless a major change in an important source is sufficient to require earlier reassessment.

---

### Source specific uncertainty

The uncertainty estimate<sub>total</sub> concerns the root of the sum of uncertainty in the data sources used ( $AD_{unc}$ ) in the square and the uncertainty of the emission factor ( $EF_{unc}$ ) in the square. The extent of the total uncertainty is here primarily determined by the greatest AD or EF uncertainty.

$$\text{Uncertainty estimate}_{\text{total}} = \sqrt{(AD_{unc}^2 + EF_{unc}^2)} \quad (10.5)$$

The uncertainty estimates concerning the data sources (AD) and emission factors (EF) used, and the total uncertainty estimate, are listed in the following Table 10.3.

---

**Table 10.3**

*Uncertainty estimates for N<sub>2</sub>O from CRF sector 3D agricultural soils*

| IPCC | Category  | $AD_{unc}$ | $EF_{unc}$ | Uncertainty estimate <sub>total</sub> |
|------|---|------------|------------|---------------------------------------|
| 3Da  | Direct N <sub>2</sub> O emissions from agricultural soils             | 10         | 60         | 61                                    |
| 3Da3 | Animal production on agricultural soils                               | 10         | 100        | 100                                   |
| 3Db  | Indirect N <sub>2</sub> O emissions from nitrogen used in agriculture | 50         | 200        | 206                                   |

A detailed overview of quality assurance and quality control is given in Annex 12. In this annex also some outlines on the verification of data are presented.

---

# 11 PM<sub>10/2.5</sub> emissions from crop production and agricultural soils (NFR category 3D)

## 11.1 Scope and definition

The Nomenclature For Reporting (NFR) source category 3D Crop production and agricultural soils consists of:

- 3Dc Farm-level agricultural operations including storage, handling and transport of agricultural products
- 3De Cultivated crops

PM emissions occurring during the use of inorganic N-fertilizers, take place during the loading of the applicator. Therefore these are not reported under category 3Da1 Inorganic N-fertilizers (includes also urea application) but 3Dc Farm-level agricultural operations including storage, handling and transport of agricultural products. No emissions of PM occur in the source categories 3Da2a Livestock manure applied to soils, 3Da2a Sewage sludge applied to soils, 3Da2c Other organic fertilizers applied to soils (including compost), 3Da3 Urine and dung deposited by grazing animals, 3Da4 Crop residues applied to soils and 3Db Indirect emissions from managed soils. Activities under 3Dd Off-farm storage, handling and transport of bulk agricultural products are covered by other sectors, and emissions in category 3Df Use of pesticides are included within 3Dc Farm-level agricultural operations including storage, handling and transport of agricultural products. Since field burning is prohibited by law no emissions take place in category 3F Field burning of agricultural residues. Lastly the Netherlands chose not to report emissions under category 3I Agriculture other.

Particulate matter emissions from crop production occur during soil cultivation or crop harvesting, and depend on crop sort, soil type, methods used and the weather. Also during other agricultural activities particulate matter is being emitted (e.g. during haymaking and in the use of concentrates, inorganic N-fertilizers and pesticides). These emissions are allocated towards categories 3De and 3Dc, respectively.

## 11.2 Calculation method

PM emissions from crop production and agricultural soils consist of PM<sub>10</sub> and PM<sub>2.5</sub> for crop cultivation and the use of concentrates, fertilizer and pesticides. PM emissions from crop cultivation are calculated using a Tier 2 method. The area of each crop is multiplied by emission factors for soil cultivation, harvesting, cleaning and drying in wet climate conditions. PM emissions during transport and handling of concentrates, fertilizer and pesticide have been calculated once using a country specific method (Chardon and Van der Hoek, 2002) and kept constant for the whole time series. The total PM emissions from all supply sources are then calculated by adding up the PM emissions per supply source.

Crop cultivation is calculated using formula 11.1:

$$\text{PM emission (kg PM)} = \sum \text{area}_q \times \text{EF}_q \times n \quad (11.1)$$

In which

$\text{area}_q$  : Cropped area for the defined crop (q) (ha)

$\text{EF}_q$  : Emission factor for the defined crop (q) in kg per ha

n : Number of times the operation is performed on the crop

The emission factor in aforementioned formula takes into account the following operations:

1. soil cultivation
2. harvesting
3. cleaning
4. drying

The emission of haymaking has been calculated by multiplying the production by an emission factor. But due to uncertainties the emission is kept constant during the time series.

These emissions are being reported under NFR category 3De Cultivated crops.

#### Comparison to EMEP methodology

The methodology described above conforms to the EMEP method.

### 11.3 Emission factors

For emissions that arise during the tillage of crops, EMEP default emission factors are used (EEA, 2009). A number of other sources (haymaking and the usage of concentrates, synthetic fertilizer and pesticides) have an additional estimate, as derived by Chardon and Van der Hoek (2002). Table 11.1 presents an overview.

Table 11.1

*Emission factors for particulate matter from crops and added estimates for other sources*

|                       | PM <sub>10</sub>                 | PM <sub>2.5</sub> |
|-----------------------|----------------------------------|-------------------|
|                       | <i>Emission factor (kg/ha)</i>   |                   |
| Wheat                 | 1.49                             | 0.212             |
| Barley                | 1.25                             | 0.168             |
| Rye                   | 1.15                             | 0.149             |
| Oats                  | 1.78                             | 0.251             |
| Other crops           | 0.25                             | 0.015             |
|                       | <i>Added estimate (ton/year)</i> |                   |
| Haymaking             | 6.0                              | 1.2               |
| Concentrates          | 90.0                             | 18.0              |
| Synthetic fertilizers | 105.0                            | 21.0              |
| Pesticides            | 125.0                            | 25.0              |

Source: EEA (2009), Chardon and Van der Hoek (2002).

### 11.4 Activity data

Information on the areas used for crop production are taken from the Agricultural Census.

### 11.5 Uncertainty and quality

The uncertainty estimate<sub>total</sub> concerns the root of the sum of uncertainty in the data sources used (AD<sub>unc</sub>) in the square and the uncertainty of the emission factors (EF<sub>unc</sub>) in the square. The extent of the total uncertainty is here primarily determined by the greatest AD or EF uncertainty.

$$\text{Uncertainty estimate}_{\text{total}} = \sqrt{(AD_{\text{unc}}^2 + EF_{\text{unc}}^2)} \quad (11.2)$$

The uncertainty of PM<sub>10/2.5</sub> emissions as a result of crop production and agricultural soils, based on expert judgement is to be determined within the next uncertainty assessment.

A detailed overview of quality assurance and quality control is given in Annex 12. In this annex also some outlines on the verification of data are presented.

---

# 12 CO<sub>2</sub> emissions from liming (CRF category 3G)

## 12.1 Scope and definition

Calcareous fertilizers (calcic limestone (CaCO<sub>3</sub>) and dolomite (CaMg(CO<sub>3</sub>)<sub>2</sub>)) are used to reduce soil acidity. CO<sub>2</sub> emissions occur as the carbonate lime dissolves and releases bicarbonate. Bicarbonate (2HCO<sub>3</sub><sup>-</sup>) evolves into H<sub>2</sub>O and CO<sub>2</sub>.

## 12.2 Calculation method

CO<sub>2</sub> emissions as a result of using lime on agricultural soils are determined for reporting in Table 3G of the Common Reporting Format (CRF). The amounts used are reported in the Agricultural Statistics for the total of lime fertilizer products (LEI/CBS, for various years). The available figures are totals and do not specify the application on grassland and cropland separately. Since these figures are reported in CO<sub>2</sub>-eq there is no need to correct for inaccuracy and the CO<sub>2</sub> emissions can be calculated with a Tier 1 method as follows:

$$\text{CO}_2 \text{ emissions 3G} = (\text{limestone use} \times \text{EF}_{\text{limestone}} + \text{dolomite use} \times \text{EF}_{\text{dolomite}}) \times 44/12 \quad (12.1)$$

In which

CO<sub>2</sub> emissions 3G : Carbon dioxide emissions (kg CO<sub>2</sub>/year) from CRF source category 3G Liming

EF<sub>limestone</sub> : Emission factor (kg CO<sub>2</sub>-C/kg applied) for limestone

EF<sub>dolomite</sub> : Emission factor (kg CO<sub>2</sub>-C/kg applied) for dolomite

44/12 : Conversion factor from CO<sub>2</sub>-C to CO<sub>2</sub>

## 12.3 Emission factors

IPCC 2006 Tier 1 default values are used for lime use in agricultural soils, i.e. 0.12 kg CO<sub>2</sub>-C/kg limestone and 0.13 kg CO<sub>2</sub>-C/kg dolomite. These translate to 440 kg CO<sub>2</sub>/ton pure limestone and 477 kg CO<sub>2</sub>/ton pure dolomite.

## 12.4 Activity data

Information on the amount of carbonate applied to soil originate from LEI Wageningen UR. Input on carbonate use comes from the Agricultural Census described in Section 1.2 and from industrial processing records and import/export data from retailers of lime fertilizers.

## 12.5 Uncertainty and quality

The uncertainty estimate<sub>total</sub> concerns the root of the sum of uncertainty in the data sources used (AD<sub>unc</sub>) in the square and the uncertainty of the emission factors (EF<sub>unc</sub>) in the square. The extent of the total uncertainty is here primarily determined by the greatest AD or EF uncertainty.

$$\text{Uncertainty estimate}_{\text{total}} = \sqrt{(\text{AD}_{\text{unc}}^2 + \text{EF}_{\text{unc}}^2)} \quad (12.2)$$

---

The uncertainty of CO<sub>2</sub> emissions as a result of liming is based on expert judgement. Uncertainty is estimated to be 25% in total, with the uncertainty in activity data being 25% and for the emission factor 1%.

A detailed overview of quality assurance and quality control is given in Annex 12. In this annex also some outlines on the verification of data are presented.

---

# Justification

Emissions are assessed with the National Emission Model for Agriculture (NEMA), approved by the independent Dutch Scientific Committee of the Manure Act (CDM) and administrated by Statistics Netherlands (CBS). The work is guided by the task force Agriculture and Land Use (TgL) of the Pollutant Release and Transfer Register (PRTR, or 'EmissieRegistratie' (ER) in Dutch). For greenhouse gas reporting, the Netherlands Enterprise Agency (RVO.nl) reviews the proceedings acting as the National Inventory Entity (NIE).

The methodologies follow or comply with the 2006 IPCC Guidelines (greenhouse gases) and the 2013 EMEP Guidebook (air pollutants). The draft report was reviewed and approved by Peter Zijlema and Harry Vreuls (RVO.nl).

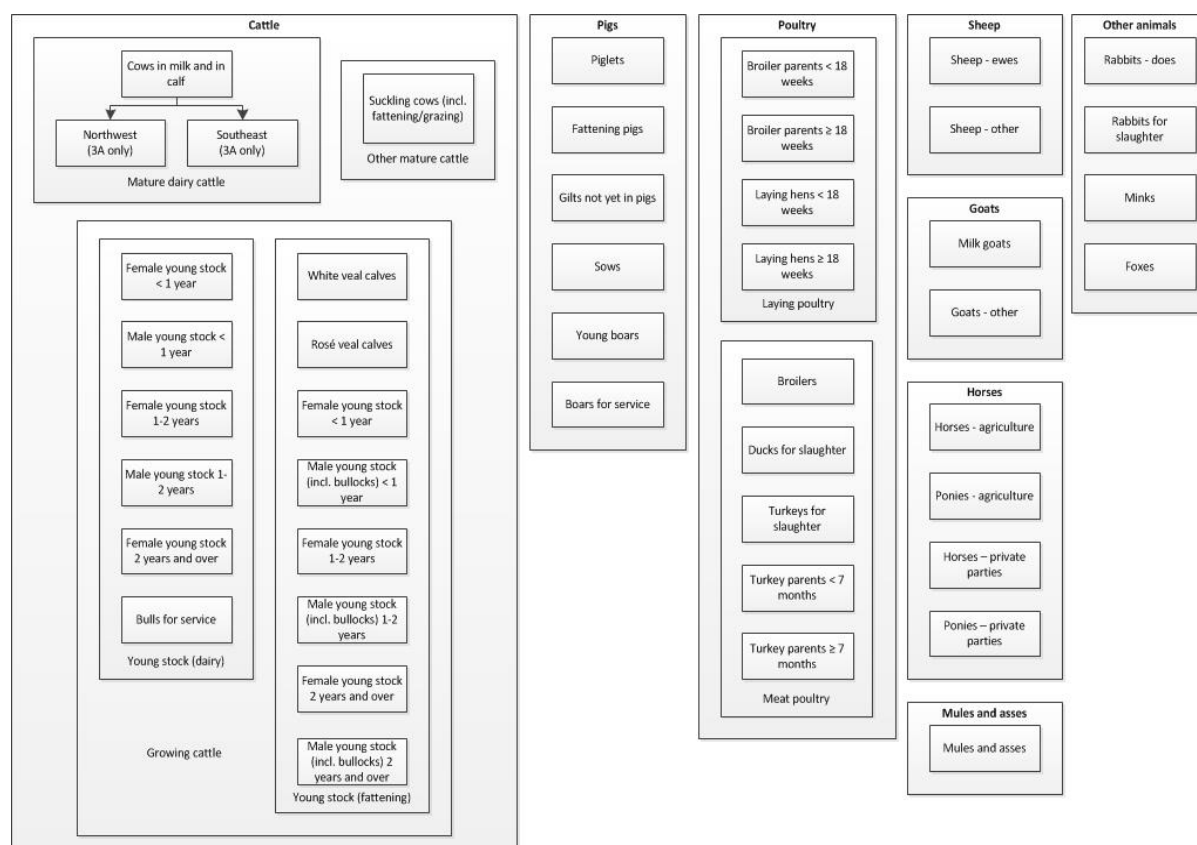

# Annex 1 Animal categories

Activity data on number of animals originates from the Agricultural Census held yearly. Under this Agricultural Census, all agricultural businesses are taken into account which have their main office in the Netherlands and which are larger than three Dutch so-called 'large animal' units (grootte-eenheden; until 2009) or 3,000 Standard Output (from 2010 onwards). For more details on population statistics the reader is referred to Statistics Netherlands, CBS ([www.cbs.nl](http://www.cbs.nl)) and Van Bruggen *et al.* (2015).

Should there be an outbreak of an animal disease, and for this reason a deviating number of animals is kept throughout the year, the Working group on Uniformity of calculations of Manure and mineral data (in Dutch: 'Werkgroep Uniformering berekening Mest- en mineralcijfers', WUM) modifies the number of animals. These updated numbers are used for the emission calculations. The calculations by the WUM are reported by CBS.

The product Boards for Livestock, Meat and Eggs estimate the Netherlands has 300,000 privately owned horses and ponies (PVE, 2005). Emissions for these animals are calculated within NEMA, but strictly speaking these are not part of agriculture. Therefore resulting emissions of ammonia, nitrogen oxides and particulate matter are attributed to NFR category 6 Other. However as the Netherlands chose not to report greenhouse gas emissions under the corresponding CRF category, methane and nitrous oxide emissions have been included within sector 3 Agriculture.

---

# Annex 2 Calculation of TAN excretion for dairy cattle and young stock

Translation with adaptation of the annex from L. Šebek & A. Bannink (Division Animal Husbandry, Animal Sciences Group (ASG), Wageningen UR) in Velthof *et al.*, 2009.

## Introduction

Until now the ammonia emission is estimated by means of an emission percentage applied on total N excretion. It is however mainly the excretion of urine N that is responsible for the ammonia emission. Therefore, the current aim is to estimate ammonia emission based on excreted urine N. Excretion of urine N is comparable to that of total ammoniacal N (TAN).

This document describes the calculation of TAN as the first step in the adaptation of the calculation methodology for ammonia emission. For dairy cattle, the year 2001 is chosen as target year since the WUM-Rav excretions are based on data for this year. For this same reason, for young cattle the data of the year 1990 was used.

A description of the calculation method of TAN is given here and results are presented for dairy cattle, young stock younger than 1 year and young stock with an age between 1 and 2 years, suckling and fattening cows, bulls for service, veal calves for white meat production between 0-6 months, veal calves for rosé meat production between 0-8 months, beef steers younger than 1 year, and beef steers older than 1 year.

## Method

### *Calculation method*

The total N excretion is calculated in accordance with the method used by the WUM, also used by Tamminga *et al.* (2000, 2004) to derive the fixed excretion figures for various animal categories. In this method the uptake of N with the separate ration components is calculated, and total N excretion as the difference between N uptake and N retained in animal products (milk, growth, offspring).

For the results reported in the present document, the same method was used but it was extended with an estimation of the digestion coefficient (DC) for crude protein (CP). Introduction of DC-CP is required to be able to calculate TAN. The calculation is performed for each feedstuff in the ration separately. With the DC-CP per feedstuff the percentage of crude protein uptake can be calculated that is absorbed by the intestine (= digested). The remainder (100% - DC-CP) of crude protein uptake leaves the body with the faeces. Protein absorbed by the intestine is either used for production (milk, growth, offspring) or excreted as urine N by the kidneys. By setting the TAN equal to the excretion of urine N, TAN is calculated by the following steps:

- summation of the amount crude protein uptake that is absorbed in the intestine for all feedstuffs in the ration,
- conversion of absorbed protein to absorbed N,
- calculation of N retained with animal production,
- calculation of excreted urine N as the difference between absorbed N and N retained with animal production.

### *Calculation of the DC-CP*

The CVB animal feed table (CVB, 2005a) lists DC-CP values (as a % of crude protein content) for all common products. For roughages this is dependent on the quality of the roughage. Regression equations have been published to calculate the DC-CP based on chemical composition (crude protein content, crude ash content and crude fibre content; CVB, 2005b). In Table A2.1 the DC-CP is given for the various ration components fed to dairy cattle or young stock.

**Table A2.1**

*The CP content, the ammonia content and the faecal CP digestibility for the various ration components in the ration of dairy cattle and young stock*

|                             | CP content <sup>1</sup> | Ammonia content | DC-CP <sup>2</sup> |
|-----------------------------|-------------------------|-----------------|--------------------|
|                             | g CP/kg DM              | % CP            | %                  |
| Fresh grass / grass herbage | 229                     | 0               | 85                 |
| Grass silage (+ hay)        | 191                     | 10              | 77                 |
| Maize silage                | 81                      | 10              | 50                 |
| Standard concentrate        | 180                     | 0               | 70                 |
| Protein-rich concentrate    | 330                     | 0               | 82                 |
| By-products <sup>3</sup>    |                         |                 |                    |
| Brewers' grains             | 250                     | 0               | 80                 |
| Potato pulp                 | 85                      | 0               | 36                 |
| Pressed sugar beet pulp     | 115                     | 0               | 65                 |
| Whole milk                  | 35                      | 0               | 86                 |

<sup>1</sup> Including ammonia N.

<sup>2</sup> Concerns an estimation of the real instead of apparent digestibility of crude protein.

<sup>3</sup> Only most abundant product in the category mentioned here (brewers' grains for category protein-rich byproducts, potato pulp for category of rest material potato processing industry, pressed sugar beet pulp for category of pulps and vegetables).

#### *Used data*

The amounts of feed that has been provided yearly to the different animal categories are according to the report of the Working group on Uniformity of Manure and mineral data (WUM). Also data are available for milk production, and the composition of roughages (based on yearly statistics on analyses of silages by Blgg), concentrates (based on reports of feed manufacturers) and byproducts (based on amounts of products marketed). These figures are recently used and described by Smink *et al.* (2005) for the calculation of the methane emission of dairy cattle and the same data are used in the present study. For moisture-rich byproducts it is assumed that these consisted of 25, 40 and 35% of brewers' grains, potato products and sugar beet pulp. This division compares well to the WUM report of the availability byproducts for cattle (respectively 26, 35 and 26%; 30:40:30 ratio).

For young stock the WUM rations of 1990 have been used in accordance with the starting points in the available WUM-Rav excretion data. The composition of roughages and concentrates was assumed equal to that of dairy cattle in the year 2001.

#### *Other starting points/assumptions*

*Correction CP content for ammonia fraction.* It was assumed that ammonia N (expressed as CP) accounted for 10% of the total CP content in both grass silage and maize silage.

#### *Correction feed uptake for so-called "feed losses".*

For the time being no corrections have been made for feed losses because these also seem not to have been made in the calculation of the N excretions in WUM-Rav. If the corrections in the feeding of dairy cattle according to the current WUM methodology (0, 5, 3 and 2% feed losses for respectively fresh grass, grass silage, maize silage, moist byproducts and concentrates) were to be made this would lead to much lower N excretions than the reported 131.0 kg N/dairy cow/year according to WUM-Rav.

#### *Composition urine N*

For the time being 100% of the urine N is considered as TAN and no differentiation is made between N holding components that do not (quickly) lead to ammonia formation (Reijs, 2007).

---

## Results

### *Dairy cattle*

For dairy cattle a total N excretion of 131.3 kg N/year/dairy cow was calculated, according to the WUM-Rav data of 131.0 kg N/year/dairy cow. The calculated N excretion of 131.3 kg N consisted of 45.7 kg faecal N excretion (35%) and 88.1 kg urine N or TAN (67%).

### *Young stock up to 1 year*

For young stock younger than 1 year a 9% lower N excretion was calculated than reported by WUM-Rav. Because the same ration composition and feed uptakes were used, reason probably is the assumption of the same N contents in grass products as in the calculation for dairy cattle in the target year 2001. Compared to 1990 the N content probably decreased and as a result the calculated N excretion decreases (Table A2.2).

A total N excretion of 40.5 kg N/animal/year was calculated, of which respectively 11.6 (29%) kg N contributed to faecal N and 28.6 (71%) kg N to urine N or TAN.

### *Young stock of 1 to 2 years*

In a similar way, and probably for the same reason as for young stock up to 1 year, for young stock of 1 to 2 years also a 9% lower N excretion was calculated than the value used in the WUM-Rav. Compared to young stock up to 1 year an approximately twice as high N excretion of 85.8 kg N/animal/year was calculated, of which respectively 19.9 (33%) kg N contributed to faecal N and 65.5 (77%) to urine N or TAN.

### *Fattening and suckling cows*

For the category fattening and suckling cows a 1% higher N excretion than reported by WUM-Rav was calculated. The calculated N excretion of 94.3 kg N/cow/year consisted of 24.0 kg faecal N excretion (25.5%) and 70.3 kg urine N or TAN (74.5%).

### *Bulls for service*

For bulls for service a N excretion was calculated identical to that reported by WUM-Rav (90.6 kg N/bull/year). This consisted of 26.8 kg faecal N (30%) and 63.7 kg urine N or TAN (70%).

### *Meat calves for white veal of 0 to 6 months*

For this category of veal calves a 3% higher N excretion was calculated than reported by WUM-Rav. The calculated N excretion of 12.0 kg N/calf/year consisted of 2.6 kg faecal N (22%) and 9.3 kg urine N or TAN (78%).

### *Meat calves for rosé veal of 0 to 8 months*

For this category of veal calves a N excretion of 28.8 kg N/calf/year was calculated identical to that reported by WUM-Rav. The calculated N excretion consisted of 12.2 kg faecal N (42%) and 16.6 kg urine N or TAN (58%).

### *Beef steers to 1 year*

For this category of beef steers the calculated N excretion of 27.4 kg N/steer/year matched the reporting of WUM-Rav. The calculated N excretion consisted of 14.0 kg faecal N (51%) and 13.3 kg urine N or TAN (49%).

### *Beef steers from 1 year*

For this category of beef steers a N excretion of 58.1 kg N/calf/year was calculated that is identical to that reported by WUM-Rav. The calculated N excretion consisted of 25.1 kg faecal N (43%) and 33.0 kg urine N or TAN (57%).

Table A2.2 presents an overview of aforementioned calculation for the various animal categories next to total N excretion reported by WUM-Rav.

Table A2.2

Overview of results for dairy cattle and young stock

|                                | Total N excretion |                   | Faecal N          | TAN               | TAN               |
|--------------------------------|-------------------|-------------------|-------------------|-------------------|-------------------|
|                                | kg N/animal/year  |                   | kg N/animal/year  |                   | % N excretion     |

### Discussion

An evaluation of the division between the excretion of faecal N and urine N (TAN) is difficult for most of the animal categories because suitable measurement data are lacking. Most measurements have been performed on dairy cattle, for which in various experiments the N excretion with faeces and urine has been collected separately and urine N was directly measured or estimated by a N balance approach. These observations do not involve a fully year cycle, as is the starting point in this study, but momentary observations of the effect of adjustments of dairy cow nutrition on excretion.

A selection of these dairy cow observations is compared with the results of this study in Table A2.3. The comparison shows that there is a large range present in the share TAN in the manure of dairy cattle. On average the % TAN in observed N excretion was lower because of a relatively lower N digestibility than calculated in this study (measured values were scaled up to a yearly excretion by multiplication of daily N excretion by 365). This is caused by feed intake and ration composition not being representative of the average ration being fed yearly to dairy cattle. The calculated % TAN however still lies within the range of measured values. On a fully grass-based ration a % TAN of 75% or more has to be expected, which is higher than the calculation for the yearly average in the current study. When replacing over half of the grass silage by maize silage (Valk, 1994) the % TAN can decrease to less than 50%, which is much lower than the calculation in this study.

Table A2.3

Comparison between calculated and measured excretions

|  | Total N excretion           | Faecal N      | TAN           | TAN           |
|--|-----------------------------|---------------|---------------|---------------|
|  | kg N/animal/year            |               |               | % N excretion |
| <b>Dairy cattle</b>  |                             |               |               |               |
| N balance with high variation in nutritional conditions (Bannink and Hindle, 2003) | 142.4 (± 35.3)              | 61.3 (± 12.7) | 79.6 (± 36.8) | 52.9 (± 11.1) |
| Valk, 1994   | 144.2 (± 43.4)              | 59.9 (± 3.8)  | 84.3 (± 45.3) | 55.5 (± 12.8) |
| <b>This study</b>  | 131.3                       | 45.7          | 88.1          | 67.1          |
| <b>Meat calves (white)</b>   |                             |               |               |               |
|  | <b>TAN as % N excretion</b> |               |               |               |
| Observations N balance (Van den Borne, 2006)                                       | 85.1 (± 3.7)                |               |               |               |
| <b>This study</b>  | 77.5                        |               |               |               |

---

A recent study of Van den Borne (2006) on white veal calves indicated that TAN on average made up 85.1% ( $\pm$  3.7%) of total N excretion. This research involved young animals with a starting weight of 150 kg that were fed experimental rations with a separate protein-rich and a lactose-rich meal. A lower N retention in the veal calves may have caused the higher N excretion with urine. The N retention observed was 43.1% ( $\pm$  3.5%) which is lower than the 48.6% calculated in the present study. A difference in ration composition and the amount of N uptake hence is the cause of the about 10% higher % TAN compared to the calculations in the present study. Nevertheless, the observed data confirm the highest % TAN value for this animal category (Table A2.2).

For other animal categories no independent observations of excretion data is available.

The balance method to separate calculated N excretion with urine and faeces is also used in other studies (Berentsen *et al.*, 1993; Jonker *et al.*, 1998; but also a general method applied in experimental research such as that of Valk *et al.*, 1994). Details of the calculation method may differ per study. In the current report, however, a simple method was chosen by using faecal CP digestibilities and observed milk N production. In other studies other approaches may have been chosen such as that of intestinal digestible protein values, a variable protein balance, or relationships with milk urea. It is expected, however, that although such calculations adopt different concepts and include detailed aspects of animal N metabolism, they generally lead to comparable outcomes on TAN.

#### *Use in the WUM methodology*

The methodology on TAN calculation and the basal assumptions used in the present document comply with those from the WUM. The results based on WUM differ to a small extent from those in the present document. The WUM calculates the TAN excretion in the animal house to be 60% of total N excretion, and 68% during the pasture period, in contrast to 67% calculated here.

### A3.1.2 The N content and the N digestibility of pig feeds

In Table A3.2 an overview is given of the N contents in the various pig feeds with which calculations have been made.

The N content in the various feeds in the reference year is for an important part derived from WUM (1994) for the year concerned and for the reference year 2001 from Jongbloed and Kemme (2005). The N content in the feeds for 2005 is for most feeds derived from Jongbloed and Van Bruggen (2008).

**Table A3.2**

*Overview of the N contents and the N digestibility (DC-N) in the various pig feeds for the reference year and 2005*

|  | Reference year |          |          | 2005     |          |
|--|----------------|----------|----------|----------|----------|
|  | Year           | N (g/kg) | DC-N (%) | N (g/kg) | DC-N (%) |
| Piglet rearing feed/weaning feed           | 1994           | 29.0     | 83.0     | 28.8     | 83.0     |
| Baby piglet feed (12-26 kg)                | 1994           | 29.0     | 83.0     | 28.8     | 83.0     |
| Starting feed (26-40 kg)                   | 1991           | 28.2     | 81.9     | 25.2     | 81.0     |
| Starting feed gilts/young boars (26-40 kg) | 2001           | 27.1     | 81.0     | 27.1     | 81.0     |
| Fattening pig feed (40-110 kg)             | 1991           | 26.0     | 80.1     | 25.2     | 78.6     |
| Gilts/young boars feed (40-125 kg)         | 2001           | 24.5     | 80.5     | 25.2     | 78.0     |
| Standard sow feed                          | 1991           | 25.7     | 79.0     | -        | -        |
| Standard sow feed                          | 1994           | 25.4     | 79.0     | -        | -        |
| Lactating sow feed                         | 1991           | 24.6     | 80.0     | 25.2     | 78.0     |
| Lactating sow feed                         | 1994           | -        | -        | 25.2     | 78.0     |
| Lactating sow feed                         | 2001           | 24.5     | 80.0     | 25.2     | 78.0     |
| Sow in pig feed                            | 1994           | -        | -        | 21.9     | 66.2     |

### *A3.1.3 Estimation of the N digestibility in the feeds*

The digestibility of N in the feeds is for the reference year based on some publications in which the resource composition of feeds was given. On enquiry with several composite feed companies no information on this was available as it is stored for only five or six years. The digestibility of N is estimated based on the given digestibilities for those according to the Animal feed table (CVB, 2007). Unfortunately only sporadic information was available of the resource composition of the feeds that were produced in 2005. In the same way as above the N digestibility was estimated. There where data were missing based on consultation with some specialists within and outside ASG a best possible estimation of the N digestibility was made.

## **A3.2 Breeding sows with piglets up to ca. 6 weeks of age (category 400)**

### *A3.2.1 Starting points*

The start weight of the sows for 1994 and for 2005 is set to 140 kg and the end weight is for 1994 and 2005 set to 205 respectively 220 kg. Based on Agrovision (1994, 2005) for 1994 calculations can be made with a farm litter index of 2.25 and for 2005 of 2.31.

The replacement of sows amounted 47% in 1994 and in 2005 this was 45% (Agrovision, 1994; 2005). According to Agrovision (1994) a breeding sow of which the piglets are weaned at 4 weeks, takes up 1,079 kg of feed per year in 1994; in 2005 that is 1,145 kg, of which circa 65% as sow in pig feed and 35% as lactating sow feed.

The number of live born piglets per litter is according to Agrovision (1994) on average 10.9 and in 2005 the number of live born piglets per litter is 12.0. The number stillborn piglets per litter was in 1994 and 2005 0.7 respectively 1.0 (Agrovision, 1994; 2005).

The weight of piglets on 42 days is 11.0 kg in 1994 and 10.8 kg in 2005. The feed uptake of piglets up to day 42 after birth is set to 4.5 kg in 1994 (Backus *et al.*, 1997) and 4.48 kg in 2005. This amount is in vast majority weaning feed.

The N content of the weaning feed in 1994 was 29.0 g/kg and in 2005 28.8 g/kg. The N digestibility in the weaning pellet is derived from the feed composition according to Kloosterman and Huiskes (1992) and was 83.3%; for 2005 83.0% is taken. The sow feed in 1994 contained 25.4 g N/kg (WUM, 1994), while in 2005 the sow in pig feed and lactating sow feed contained 21.9 respectively 25.2 g N/kg (Jongbloed and Van Bruggen, 2008). The N digestibility of the sow feed in 1994 is estimated based on the feed composition according to Everts *et al.* (1991) and was 79.0%. The N digestibility of the sow in pig feed is derived from the feed composition of a composite feed manufacturer during the first half of 2006 and was 66.2%. According to another composite feed manufacturer in 2005 the N digestibility of lactating sow feed was 78.0%.

### A3.2.2 Results breeding sows with piglets up to ca. 6 weeks of age

In Table A3.3 is based on above mentioned starting points for breeding sows with piglets up to ca. 6 weeks of age an overview given of the N housekeeping if a sow place would be occupied the whole year (no days lost).

Table A3.3

*N housekeeping (kg) by breeding sows with piglets up to ca. 6 weeks of age on yearly basis (category 400)*

| Category 400       | 1994   |      |               | 2005   |      |               |
|--------------------|--------|------|---------------|--------|------|---------------|
|                    | g N/kg | DC-N | N uptake (kg) | g N/kg | DC-N | N uptake (kg) |
| Weaning feed       | 29.0   | 83.3 | 2.71          | 28.8   | 83.0 | 3.15          |
| Sow in pig feed    | 25.4   | 78.9 | 17.81         | 21.9   | 66.2 | 16.15         |
| Lactating sow feed | 25.4   | 78.9 | 9.59          | 25.2   | 78.0 | 10.27         |
| Total uptake       |        |      | 30.12         |        |      | 29.57         |
| Fixation           |        |      | 7.13          |        |      | 7.71          |
| Excretion          |        |      | 22.98         |        |      | 21.86         |
| In faeces          |        |      | 6.2           |        |      | 8.3           |
| In urine           |        |      | 16.8          |        |      | 13.6          |
| In urine (%)       |        |      | 72.9          |        |      | 62.2          |

Table A3.3 shows that the N excretion per sow per year compared to 1994, in 2005 has decreased by over 1.0 kg and that there has been a large shift towards much more N in the faeces and much less in the urine. The percentage of the N excretion in the urine decreased from 72.9 to 62.2. This shift is mostly due to the introduction of a sow in pig feed that has to contain much raw fibre in the framework of the Pig decree (1994).

## A3.3 Breeding sows with piglets up to ca. 25 kg (category 401)

### A3.3.1 Starting points

For data of the breeding sows is referred to the previous section (the description for category 400). The weight of piglets by the start of fattening is according to Agrovision (1994; 2005) 25.7 kg in 1994 and 25.6 kg in 2005. The age at the start of fattening is on average 80 days. The amount of weaning feed taken up per piglet is 4.5 kg. Based on a feed conversion of 1.65 a piglet takes up 30.0 kg of feed before start of fattening in 1994 and in 2005 feed conversion is 1.59 so that per piglet 28.7 kg of feed is taken up (Agrovision, 1994; 2004).

The N contents of the baby piglet feed in 1994 and 2005 were 29.0 respectively 28.8 g/kg. The N digestibility of the baby piglet feed in 1994 is derived from the feed compositions according to Kloosterman and Huiskes (1992) and was 83.3%; for 2005 83.0% is taken.

### A3.3.2 Results breeding sows with piglets up to ca. 25 kg

In Table A3.4 is based on abovementioned assumptions for breeding sows with piglets up to ca. 25 kg an overview given of the N housekeeping if a sow place would be occupied the whole year (no days lost).

**Table A3.4**

*N uptake and N excretion (kg) by breeding sows with piglets up to ca. 25 kg on yearly basis (category 401)*

| Category 401       | 1994   |      |               | 2005   |      |               |
|--------------------|--------|------|---------------|--------|------|---------------|
|                    | g N/kg | DC-N | N uptake (kg) | g N/kg | DC-N | N uptake (kg) |
| Weaning feed       | 29.0   | 83.3 | 2.71          | 28.8   | 83.0 | 3.16          |
| Baby piglet feed   | 29.0   | 83.3 | 15.38         | 28.8   | 83.0 | 16.71         |
| Sow in pig feed    | 25.4   | 78.9 | 17.81         | 21.9   | 66.2 | 16.15         |
| Lactating sow feed | 25.4   | 78.9 | 9.59          | 25.2   | 78.0 | 10.27         |
| Total uptake       |        |      | 45.49         |        |      | 46.30         |
| Retention          |        |      | 14.11         |        |      | 16.53         |
| Excretion          |        |      | 31.38         |        |      | 29.77         |
| In faeces          |        |      | 8.8           |        |      | 11.1          |
| In urine           |        |      | 22.6          |        |      | 18.7          |
| In urine (%)       |        |      | 71.9          |        |      | 62.7          |

### A3.3.3 Discussion breeding sows

Table A3.3 shows that the N excretion per sow per year compared to 1994, decreased with over 1.5 kg in 2005 and that there has been a large shift towards much more N in the faeces and much less in the urine. The percentage of the N excretion in the urine has declined from 71.9 to 62.7. This shift is mainly due to the introduction of a sow in pig feed that has to contain much raw fibre in the framework of the Pig decree (1994).

It has been examined what the effect is on the excretion in faeces and urine if the N digestibility is 1% unit higher or lower. Table A3.5 gives the results of this.

**Table A3.5**

*N uptake and N excretion (kg) by breeding sows with piglets up to ca. 25 kg on yearly basis (category 401) with a higher or lower N digestibility*

| Category 401 | 1994              |                     |                    | 2005              |                     |                    |
|--------------|-------------------|---------------------|--------------------|-------------------|---------------------|--------------------|
|              | DC-N 1 unit lower | DC-N starting point | DC-N 1 unit higher | DC-N 1 unit lower | DC-N starting point | DC-N 1 unit higher |
| Total uptake | 45.49             | 49.49               | 45.49              | 46.30             | 46.30               | 46.30              |
| Excretion    | 31.38             | 31.38               | 31.38              | 29.77             | 29.77               | 29.77              |
| In faeces    | 9.26              | 8.80                | 8.35               | 11.56             | 11.10               | 10.63              |
| In urine     | 22.12             | 22.58               | 23.03              | 18.21             | 18.67               | 19.14              |
| In urine (%) | 70.5              | 71.9                | 73.4               | 61.2              | 62.7                | 64.3               |

From Table A3.5 follows that as a result of a difference in N digestibility of 2% units a shift of on average 3.0% units will occur.

## A3.4 Gilts not yet in pig of ca. 25 kg to ca. 7 months (category 402)

### A3.4.1 Starting points

The start and end weight of the gilts not yet in pig for both 2002 is set to 26 respectively 125 kg. This end weight is derived from Jongbloed and Kemme (2005). The average length of the period is calculated to be 133 days, such that the average growth is 744 g/day. In 2002 the ratio between the starting feed and rearing feed for gilts not yet in pig is set to 15:85 (Jongbloed and Kemme, 2005). The total amount of feed during the lay on period for this category of gilts not yet in pig is 287 kg for 2002. For 2005 the same starting points as for 2002 are taken. The N contents of the starting feed and rearing feed in 2002 were 27.1 respectively 24.5 g/kg. For 2005 these contents are 27.1 respectively 25.2 g/kg. The N digestibility of the starting feed is set to 81.0 and of the rearing feed to 78.0 which is equal to the N digestibility of the lactating sow feed.

### A3.4.2 Results gilts not yet in pig of 25 kg to ca. 7 months

In Table A3.6 is based on abovementioned starting points for gilts not yet in pig to ca. 7 months an overview given of the N housekeeping if a pig place would be occupied the whole year (no lost days).

Table A3.6

*N uptake and excretion (kg) by gilts not yet in pig of 25 kg to ca. 7 months on yearly basis (category 402)*

| Category 402       | 2001   |      |               | 2005   |      |               |
|--------------------|--------|------|---------------|--------|------|---------------|
|                    | g N/kg | DC-N | N uptake (kg) | g N/kg | DC-N | N uptake (kg) |
| Starting feed      | 27.1   | 81.0 | 4.27          | 27.1   | 81.0 | 4.27          |
| Lactating sow feed | 24.5   | 80.0 | 15.44         | 25.2   | 78.0 | 15.88         |
| Total uptake       |        |      | 19.71         |        |      | 20.15         |
| Retention          |        |      | 6.77          |        |      | 6.77          |
| Excretion          |        |      | 12.93         |        |      | 13.38         |
| In faeces          |        |      | 3.9           |        |      | 4.3           |
| In urine           |        |      | 9.0           |        |      | 9.1           |
| In urine (%)       |        |      | 69.9          |        |      | 67.8          |

Table A3.6 shows that the N excretion per gilt not yet in pig compared to 2001 decreased somewhat in 2005 and that there has been a shift to more N in the faeces. The percentage of the N excretion in the urine has decreased from 69.9 to 67.8.

## A3.5 Gilts not yet in pig of ca. 7 months to first mating (category 403)

### A3.5.1 Starting points

The start and end weight of these gilts not yet in pig for both 2002 and 2006 is set to 125 respectively 140 kg (Topigs, 2004). According to this reference it follows that the age at first insemination on average is 243 days, thus the average length of the period can be set to 30 days in 2001 and 2005. The average growth is 500 g/day.

The total amount of the lactating sow feed during the lay on period for this category gilts not yet in pig, is calculated to 72 kg for 2001 and 2005.

The N contents of the lactating sow feed in 2001 and 2005 are 24.5 respectively 25.2 g/kg. The N digestibility of the lactating sow feed is 80.0 respectively 78.0%.

### A3.5.2 Results gilts not yet in pig of ca. 7 months to first mating

In Table A3.7 is based on abovementioned starting points for this category gilts not yet in pig an overview given of the N excretion if a pig place would be occupied for the whole year (no loss of days).

**Table A3.7**

*N uptake and excretion (kg) by gilts not yet in pig of ca. 7 months to first mating on yearly basis (category 403)*

| Category 403       | 2001   |      |               | 2005   |      |               |
|--------------------|--------|------|---------------|--------|------|---------------|
|                    | g N/kg | DC-N | N uptake (kg) | g N/kg | DC-N | N uptake (kg) |
| Lactating sow feed | 24.5   | 80.0 | 21.46         | 25.2   | 78.0 | 22.08         |
| Fixation           |        |      | 4.54          |        |      | 4.54          |
| Excretion          |        |      | 16.92         |        |      | 17.53         |
| In faeces          |        |      | 4.3           |        |      | 4.9           |
| In urine           |        |      | 12.6          |        |      | 12.7          |
| In urine (%)       |        |      | 74.6          |        |      | 72.3          |

Table A3.7 shows that the N excretion per gilt not yet in pig compared to 2001 increased somewhat in 2005 and that there has been a shift to more N in the faeces. The percentage of the N excretion in the urine decreased from 74.6 to 72.3%.

## A3.6 Gilts not yet in pig of ca. 25 kg to first mating (category 404)

### A3.6.1 Starting points

The begin and end weight of the gilts not yet in pig for both 2001 and 2005 is set to 26 respectively 140 kg (for more details see the description for categories 402 and 403). The average length of the period is calculated to 163 days, so that the average growth is 699 g/day. In 2002 the ratio between the starting feed, rearing feed and lactating sow feed for gilts not yet in pig during the lay on period is set to 16:64:20, and for 2006 to 4:76:20 (Jongbloed and Kemme, 2005). The total amount of feed during the lay on period for this category gilts not yet in pig for 2001 and 2005 is 359 kg. For 2005 further the same starting points as for 2001 are taken.

The N contents of the starting feed, gilts not yet in pig feed and lactating sow feed in 2001 were 27.1, 24.5 respectively 24.5 g/kg. For 2005 the contents in these feeds are 27.1, 25.2 respectively 25.2 g/kg. The N digestibility of the feeds in 2001 is set to 81.0, 80.5 respectively 80.0%, while those for 2005 were 81.0%, 79.0% respectively 79.0%.

### A3.6.2 Results gilts not yet in pig of 25 kg to first mating

In Table A3.8 is based on abovementioned starting points for gilts not yet in pig an overview given of the N housekeeping if a pig place were to be occupied the whole year (no loss of days).

**Table A3.8**

*N uptake and excretion (kg) by gilts not yet in pig of 25 kg to first mating on yearly basis (category 404)*

| Category 404              | 2001   |      |               | 2005   |      |               |
|---------------------------|--------|------|---------------|--------|------|---------------|
|                           | g N/kg | DC-N | N uptake (kg) | g N/kg | DC-N | N uptake (kg) |
| Starting feed             | 27.1   | 81.0 | 3.49          | 27.1   | 81.0 | 3.49          |
| Gilts not yet in pig feed | 24.5   | 80.5 | 12.61         | 25.2   | 78.0 | 15.40         |
| Lactating sow feed        | 24.5   | 80.0 | 3.94          | 25.2   | 78.0 | 1.62          |
| Total uptake              |        |      | 20.03         |        |      | 20.50         |
| Fixation                  |        |      | 6.36          |        |      | 6.36          |
| Excretion                 |        |      | 13.67         |        |      | 14.14         |
| In faeces                 |        |      | 3.9           |        |      | 4.4           |
| In urine                  |        |      | 9.8           |        |      | 9.7           |
| In urine (%)              |        |      | 71.4          |        |      | 68.8          |

Table A3.8 shows that the N excretion per gilt not yet in pig per year compared to 2001 increased somewhat in 2005 and that a shift occurred to more N in the faeces. The percentage of the N excretion in the urine has decreased from 71.4 to 68.8%.

## A3.7 Young boars of ca. 25 kg to ca. 7 months (category 405)

### A3.7.1 Starting points

The start and end weight of the young boars for both 2001 as 2005 is set to 26 respectively 135 kg. The average length of the period is 133 days in 2001 and 2005, so that the average growth per animal per day is 820 grams. In 2001 and 2005 the feed conversion of this category pigs is 2.66. In 2001 and also 2005 during the lay on period a ratio between starting feed, growth feed and finishing feed of 15:20:65 is taken (Jongbloed and Kemme, 2005). This ratio is applied on the total amount of feed (290 kg).

The N contents of the starting feed, growth feed and finishing feed in 2001 were 27.1, 24.5 respectively 25.7 g/kg. These contents in 2005 were 27.1, 25.2 respectively 25.2 g/kg.

The N digestibility of the feeds was in 2001 81.0%, 80.5% respectively 80.5% and in 2005 81.0%, 78.0% respectively 81.0%.

### A3.7.2 Results young boars

In Table A3.9 is based on abovementioned starting points for young boars an overview given of the N housekeeping if a pig place were to be occupied the whole year (no loss of days).

**Table A3.9**

*N uptake and excretion (kg) by young boars to ca. 7 months on yearly basis (category 405)*

| Category 405       | 1991   |      |               | 2005   |      |               |
|--------------------|--------|------|---------------|--------|------|---------------|
|                    | g N/kg | DC-N | N uptake (kg) | g N/kg | DC-N | N uptake (kg) |
| Starting feed      | 27.1   | 81.0 | 3.24          | 27.1   | 81.0 | 3.24          |
| Lactating sow feed | 24.5   | 80.5 | 16.57         | 25.2   | 78.0 | 17.05         |
| Total uptake       |        |      | 19.81         |        |      | 20.28         |
| Fixation           |        |      | 7.46          |        |      | 7.45          |

| Category 405 | 1991   |      |               | 2005   |      |               |
|--------------|--------|------|---------------|--------|------|---------------|
|              | g N/kg | DC-N | N uptake (kg) | g N/kg | DC-N | N uptake (kg) |
| Excretion    |        |      | 12.35         |        |      | 12.83         |
| In faeces    |        |      | 3.8           |        |      | 4.4           |
| In urine     |        |      | 8.5           |        |      | 8.5           |
| In urine (%) |        |      | 68.9          |        |      | 66.0          |

Table A3.9 shows that the N excretion per young boar per year compared to 2001 increased somewhat in 2005 and that a shift occurred toward more N in the faeces. The percentage of the N excretion in the urine decreased from 68.9 to 66.0%.

## A3.8 Breeding boars of ca. 7 months and older (category 406)

### A3.8.1 Starting points

The start and end weight of the breeding boars for 1991 is set to 130 kg respectively 300 kg, for 2005 these weights are 135 kg respectively 325 kg. The average length of the period that these breeding boars are present is 548 days (WUM, 1994) which is also taken for 2005. The average feed uptake in 1991 is set to 2.9 kg/day (WUM, 1994) and in 2005 3.0 kg/day (Jongbloed and Kemme, 2005).

The N content of the feed that is given to breeding boars (sow feed) was in 1991 25.7 g/kg and in 2005 the lactating sow feed contained 25.2 g/kg. The N digestibility in the sow feed was in 1991 and 2005 78.9% respectively 78.0%.

### A3.8.2 Results breeding boars older than 7 months

In Table A2.10 is based on abovementioned assumptions for breeding boars an overview given of the N housekeeping if a pig place would be occupied the whole year (no loss of days).

**Table A3.10**

*N uptake and excretion (kg) by breeding boars of 7 months and older on yearly basis (category 406)*

| Category 406       | 1991   |      |               | 2005   |      |               |
|--------------------|--------|------|---------------|--------|------|---------------|
|                    | g N/kg | DC-N | N uptake (kg) | g N/kg | DC-N | N uptake (kg) |
| Lactating sow feed | 25.7   | 78.9 | 27.20         | 25.2   | 78.0 | 27.59         |
| Fixation           |        |      | 2.90          |        |      | 3.18          |
| Excretion          |        |      | 24.30         |        |      | 24.42         |
| In faeces          |        |      | 5.7           |        |      | 6.1           |
| In urine           |        |      | 18.6          |        |      | 18.3          |
| In urine (%)       |        |      | 76.4          |        |      | 75.1          |

Table A3.10 shows that the N excretion per breeding boar compared to 1991 remained almost the same in 2005 and that a shift has occurred towards more N in the faeces. The percentage of the N excretion in the urine has decreased from 76.4 to 75.1%.

## A3.9 Piglets of ca. 6 weeks to ca. 25 kg (category 407)

### A3.9.1 Starting points

The start and end weight of the piglets for 1994 was 11.0 respectively 25.7 kg. For 2005 the weights are set to 10.8 respectively 25.6 kg. The average length of the period is 33 respectively 38 days. The average growth is for 1994 and 2005 445 respectively 389 g per animal per day. The feed conversion of this category piglets in 1994 was 1.74 and is 1.72 in 2005. The N content of the baby piglet feed is 1994 was 29.0 and in 2005 this content was 28.8 g/kg. The N digestibility of the baby piglet feed is in 1994 and 2005 83.0%.

### A3.9.2 Results piglets of 6 weeks to 25 kg

In Table A3.11 is based on abovementioned assumptions for piglets of 6 weeks to ca. 25 kg an overview given of the N housekeeping as a pig place would be occupied the whole year (no loss of days).

Table A3.11

*N uptake and excretion (kg) by piglets of 6 weeks to ca. 25 kg on yearly basis (category 407)*

| Category 407       | 1994   |      |               | 2005   |      |               |
|--------------------|--------|------|---------------|--------|------|---------------|
|                    | g N/kg | DC-N | N uptake (kg) | g N/kg | DC-N | N uptake (kg) |
| Uptake piglet feed | 29.0   | 83.0 | 8.18          | 28.8   | 83.0 | 7.04          |
| Fixation           |        |      | 3.92          |        |      | 3.56          |
| Excretion          |        |      | 4.26          |        |      | 3.48          |
| In faeces          |        |      | 1.4           |        |      | 1.2           |
| In urine           |        |      | 2.9           |        |      | 2.3           |
| In urine (%)       |        |      | 67.3          |        |      | 65.6          |

Table A3.11 shows that the N excretion per weaned piglet of 6 weeks to ca. 25 kg per year compared to 1994 decreased considerably in 2005 and that considerably less N is excreted through the urine. The percentage of the N excretion in the urine decreased from 67.3 to 65.6%.

## A3.10 Sows for slaughter (category 410)

### A3.10.1 Starting points

The start and end weight of the sows for slaughter in 1994 is 205 kg and for 2005 220 kg. The average length of the period kept is 7 days. It is assumed that in both years per day 3 kg lactating sow feed is taken up.

The N content of the sow feed in 1994 was 24.5 g/kg and of the lactating sow feed in 2005 25.2 g/kg. The N digestibility of these feeds was 78.9 respectively 78.0%.

### A3.10.2 Results sows for slaughter

In Table A3.12 is based on abovementioned assumptions for sows for slaughter an overview given of the N housekeeping if a pig place would be occupied the whole year (no loss of days).

Table A3.12 shows that the N excretion per sow for slaughter per year compared to 1994 remained almost equal in 2005 and that the percentage of the N excretion in the urine decreased somewhat from 78.9 to 78.0%.

**Table A3.12***N uptake and excretion (kg) by sows for slaughter of 220 kg on yearly basis (category 410)*

| Category 410    | 1994   |      |               | 2005   |      |               |
|-----------------|--------|------|---------------|--------|------|---------------|
|                 | g N/kg | DC-N | N uptake (kg) | g N/kg | DC-N | N uptake (kg) |
| Uptake sow feed | 24.5   | 78.9 | 26.83         | 25.2   | 78.0 | 27.59         |
| Fixation        |        |      | 0.0           |        |      | 0.0           |
| Excretion       |        |      | 26.83         |        |      | 27.59         |
| In faeces       |        |      | 5.7           |        |      | 6.1           |
| In urine        |        |      | 21.2          |        |      | 21.5          |
| In urine (%)    |        |      | 78.9          |        |      | 78.0          |

## A3.11 Fattening pigs of ca. 25 to ca. 110 kg (category 411)

### A3.11.1 Starting points

The start and end weight of the pigs in 1991 is set to 25 respectively 109 kg (WUM, 1994). In 2005 these weights are 25.6 respectively 115.7 kg (Agrovisión, 2005). The average growth per animal per day was 712 g in 1991 (WUM, 1994) and in 2005 that was 773 g (Agrovisión, 2005). The length of the growth period was therefore 118 respectively 117 days. The feed conversion of the fattening pigs was 2.87 in 1991 and in 2005 that was 2.67. In 1991 during the first part of the lay on period an average amount of 44 kg starting feed and 197 kg fattening pig feed was given (WUM, 1994). In 2005 45 kg starting feed per pig was taken up, 70 kg growth feed and 126 kg finishing feed (Agrovisión, 2005). The N content of the starting feed and fattening pig feed in 1991 was 28.2 respectively 26.0 g/kg. For 2005 these contents in the feeds are on average 25.2 g/kg (Jongbloed and Van Bruggen, 2008). The N digestibility of the starting feed in 1991 is estimated based on the raw material composition according to Van der Peet-Schwering (1990) and Kloosterman and Huiskes (1992) and was on average 81.9%. The N digestibility of the fattening pig feed in 1991 is estimated based on the raw material composition according to Van der Peet-Schwering (1990), Kloosterman and Huiskes (1992) and Wahle and Huiskes (1992) and was on average 80.1%.

The N digestibility of the starting feed in 2005 is estimated based on the starting point that as result of the addition of amino acids and somewhat different raw materials, so that it is ca. 1% unit lower than in 1991 and thus 81.0% is assumed. The N digestibility of the fattening pig feed in 2005 is estimated based on the raw material composition of a composite feed manufacturer in the first half year of 2006, and was on average 78.6% of the feeds with an energy value of 1.05 and 1.10.

### A3.11.2 Results fattening pigs

In Table A3.13 is based on abovementioned starting points for fattening pigs an overview given of the N housekeeping if a pig place would be occupied during the whole year (no lost days).

**Table A3.13***N uptake and excretion (kg) by fattening pigs of ca. 25 to 114 kg on yearly basis (category 411)*

| Category 411       | 1991   |      |               | 2005   |      |               |
|--------------------|--------|------|---------------|--------|------|---------------|
|                    | g N/kg | DC-N | N uptake (kg) | g N/kg | DC-N | N uptake (kg) |
| Starting feed      | 28.2   | 81.9 | 3.83          | 25.2   | 81.0 | 3.55          |
| Fattening pig feed | 26.0   | 80.1 | 15.83         | 25.2   | 78.6 | 15.43         |
| Total uptake       |        |      | 19.66         |        |      | 18.98         |
| Fixation           |        |      | 5.97          |        |      | 7.07          |
| Excretion          |        |      | 13.70         |        |      | 11.91         |
| In faeces          |        |      | 3.8           |        |      | 4.0           |
| In urine           |        |      | 9.8           |        |      | 7.9           |
| In urine (%)       |        |      | 71.9          |        |      | 66.6          |

### A3.11.3 Discussion fattening pigs

Table A3.13 shows that the N excretion per fattening pig per year compared to 1991 decreased considerably in 2005. As result of the higher N retention the percentage of the N excretion in the urine decreased considerably from 71.9 to 66.6%.

For fattening pigs is examined what the effect is on the excretion in faeces and urine if the digestibility of N in the feeds for fattening pigs is 1% unit lower or higher than in the starting situation (Table A3.14).

Table A3.14

*N uptake and excretion (kg) by fattening pigs of ca. 25 to 114 kg on yearly basis (category 411) at a higher or lower N digestibility*

| Category 411 | 1991              |                     |                    | 2005              |                     |                    |
|--------------|-------------------|---------------------|--------------------|-------------------|---------------------|--------------------|
|              | DC-N 1 unit lower | DC-N starting point | DC-N 1 unit higher | DC-N 1 unit lower | DC-N starting point | DC-N 1 unit higher |
| Total uptake | 19.66             | 19.66               | 19.66              | 18.98             | 18.98               | 18.98              |
| Excretion    | 13.70             | 13.70               | 13.70              | 11.91             | 11.91               | 11.91              |
| In faeces    | 4.04              | 3.84                | 3.65               | 4.17              | 3.98                | 3.79               |
| In urine     | 9.65              | 9.85                | 10.05              | 7.75              | 7.94                | 8.13               |
| In urine (%) | 70.5              | 71.9                | 73.4               | 65.0              | 66.6                | 68.2               |

From Table A3.14 it can be seen that in the dependability of the digestibility of N with a deviation of 2% units, no large shifts occur in the division of N over faeces and urine; this is a difference of 2.9% units in 1991 and 3.2% units in 2005.

## A3.12 General discussion

An important attention point is a good insight in the N contents of the various feeds. Also because the use of a whole range of feeds for various categories pigs it is sometimes difficult to know how long those feeds are given. However by means of data from Levies Office (Bureau Heffingen) that insight can be obtained for some important feeds but are lacking for small animal categories. This needs to receive more attention.

Another point is the N digestibility. Also because of a storage period of five to six years, data on this are lacking in the compound feed industry particularly for the reference years (1991 to 2002). The N digestibility also is not of interest in the formation of the feeds: for protein this is based on ileal or faecal digestible amino acids. Also for the year 2005 it was not possible to gain a reliable insight in the N digestibility. Besides there is such a large array of feeds that it is difficult to classify these correctly. It is hard for the compound feed industry to calculate these data, and possibly competition is a reason not to make these available after all. Ways should be found to obtain more reliable data on the N digestibility in the feeds.

## A3.13 Summary pigs

In Table A3.15 a summary is given of the excretion of N and % TAN by various categories of pigs in the reference year and in 2005 in g/year.

**Table A3.15**

*Overview of the excretion of N and % TAN by the various categories of pigs in the reference year and 2005 (kg/year)*

| Category   | Number | Ref. year | N in ref. year | % TAN in ref. year | N in 2005 | % TAN in 2005 |
|--|--------|-----------|----------------|--------------------|-----------|---------------|
| Breeding sows with piglets up to 6 weeks of age      | 400    | 1994      | 23.0           | 72.9               | 21.9      | 62.2          |
| Breeding sows with piglets to ca. 25 kg              | 401    | 1994      | 31.4           | 71.9               | 29.8      | 62.7          |
| Gilts not yet in pig of ca. 25 kg to ca. 7 months    | 402    | 2001      | 12.9           | 69.9               | 13.4      | 67.8          |
| Gilts not yet in pig of ca. 7 months to first mating | 403    | 2001      | 16.9           | 74.6               | 17.5      | 72.3          |
| Gilts not yet in pig of ca. 25 kg to ca. 7 months    | 404    | 2001      | 13.7           | 71.4               | 14.1      | 68.8          |
| Young boars of ca. 25 kg to ca. 7 months             | 405    | 1991      | 12.4           | 68.9               | 12.8      | 66.0          |
| Breeding boars of ca. 7 months and older             | 406    | 1991      | 24.3           | 76.4               | 24.4      | 75.1          |
| Piglets of ca. 6 weeks to ca. 25 kg                  | 407    | 1991      | 4.3            | 67.3               | 3.5       | 65.6          |

# Annex 4 Calculation of TAN excretion for poultry

Translation with adaptation of the annex from Age Jongbloed (Animal Sciences Group (ASG), Wageningen UR, Lelystad) in Velthof *et al.*, 2009.

## A4.1 The excretion of nitrogen in the poultry sector

### A4.1.1 Calculation methodology

For the approach followed reference can be made to Section A3.1.2 and Section A3.1.3 (see Annex 3).

### A4.1.2 Contents of nitrogen in chickens and chicken eggs

In Table A4.1 is indicated what are the N contents (g per kg live weight or per kg produce) for the animal categories distinguished. Also the references are indicated. The start weight of day-old chickens for respectively the meat sector and the laying sector is set to 42 and 36 g in these calculations.

**Table A4.1**

#### A4.1.3 The N content and N digestibility in chicken feeds

In Table A4.2 an overview is given of the N contents and the digestibility of N in the various chicken feeds with which calculations are made in this study. In the corresponding sections the basis for the N contents and the N digestibility in the feeds is described further.

**Table A4.2**

*Overview of the N contents and the N digestibility (DC-N) in the various chicken feeds for the reference year and in 2005*

| Feed type                               | Reference year |        |          | 2005   |          |
|---|----------------|--------|----------|--------|----------|
|   | Year           | g N/kg | DC-N (%) | g N/kg | DC-N (%) |
| Laying hens feed 1                      | 1993           | 29.1   | 83.1     | 24.9   | 84.5     |

## A4.2 Rearing hens and roosters of laying varieties younger than ca. 18 weeks in battery housing (category 300A)

### A4.2.1 Starting points

The start weight of the rearing laying hens for both 1993 and 2005 is set to 35 g (Reuvekamp, 2004). The end weight of this category in 1993 is for middle heavy and white laying hens 1,420 respectively 1,215 g (KWIN-V, 1991). For 2005 these weights are 1,520 respectively 1,285 g. The length of the rearing period is 122.5 respectively 119 days (KWIN-V, 1991; 2005). The division over middle heavy and white laying hens in battery housing was in 1991 56:44 (WUM, 1994) and for 2005 50:50 is taken (Cijferinfo Pluimveesector 99/11; PVE, 1999). Per rearing period is for 1991 the feed uptake per delivered hen respectively 5.6 and 5.0 kg (KWIN-V, 1991) resulting in 5.5 and 4.9 kg feed per hen present for middle heavy and white laying hens (on average 5.2 kg) and a feed conversion of 4.04. The ratio between uptake of rearing feed 1 and 2 is in 1991 20:80. For 2005 the feed uptake per rearing period per delivered hen for middle heavy and white laying hens 5.6 respectively 5.2 kg (per hen present 5.4 respectively 5.2 kg), resulting in an average feed uptake of 5.3 kg per hen present and a feed conversion of 3.87. The ratio between uptake of start feed, rearing feed 1 and 2 in 2005 is 5.6:25.9:68.5 (KWIN-V, 2005).

The loss of animals amounts for 1991 to 4.5% for both middle heavy and white laying hens and for 2005 that is 3.0 respectively 5.0%. This percentage is only used for conversion of delivered hen to average present hen. In 1991 the rearing feeds contained on average 31.3 g N/kg, while these feeds in 2005 contained on average 26.1 g N/kg. The digestibility of the rearing feeds in 1991 is derived from the feed compositions of Van Niekerk and Reuvekamp (1994; 1995a and 1995b). For rearing feed 1 there were three observations just like as for rearing feed 2. For the start feed the digestibility of the rearing feed 1 is taken. Because of the lack of data about composition and N digestibility of rearing feeds in 2005 the same N digestibilities as for 1991 are taken.

### A4.2.2 Results rearing hens and roosters of laying varieties younger than ca. 18 weeks in battery housing

In Table A4.3a is based on abovementioned starting points an overview given of the N uptake and excretion for rearing hens and roosters of laying varieties younger than ca. 18 weeks housed in batteries. Also in Table A4.3b and A4.3c the results are presented if 100% rearing hens respectively middle heavy (brown) rearing hens are kept. The calculated excretion is expressed per animal year (1 animal present the whole year).

Table A4.3a

*N housekeeping (g) by rearing hens and roosters (ca. 50% white) of laying varieties younger than ca. 18 weeks in battery housing in kg N per animal year (category 300A)*

| Category 300A  | 1991   |          |              | 2005   |          |              |
|----------------|--------|----------|--------------|--------|----------|--------------|
|                | g N/kg | DC-N (%) | N uptake (g) | g N/kg | DC-N (%) | N uptake (g) |
| Start feed     | -      | -        | -            | 26.1   | 80.7     | 24           |
| Rearing feed 1 | 31.3   | 80.7     | 96           | 26.1   | 80.7     | 110          |
| Rearing feed 2 | 31.3   | 79.1     | 405          | 26.1   | 79.1     | 290          |
| Total uptake   |        |          | 501          |        |          | 424          |
| Fixation       |        |          | 112          |        |          | 117          |
| Excretion      |        |          | 389          |        |          | 307          |
| In faeces      |        |          | 103          |        |          | 86           |
| In urine       |        |          | 286          |        |          | 220          |
| In urine (%)   |        |          | 73.5         |        |          | 71.8         |

**Table A4.3b**

*N housekeeping (g) by rearing hens and roosters (100% white) of laying varieties younger than ca. 18 weeks in battery housing in kg N per animal year (category 300A)*

| Category 300A  | 1991   |          |              | 2005   |          |              |
|----------------|--------|----------|--------------|--------|----------|--------------|
|                | g N/kg | DC-N (%) | N uptake (g) | g N/kg | DC-N (%) | N uptake (g) |
| Start feed     | -      | -        | -            | 26.1   | 80.7     | 23           |
| Rearing feed 1 | 31.3   | 80.7     | 96           | 26.1   | 80.7     | 105          |
| Rearing feed 2 | 31.3   | 79.1     | 360          | 26.1   | 79.1     | 281          |
| Total uptake   |        |          | 456          |        |          | 410          |
| Fixation       |        |          | 99           |        |          | 107          |
| Excretion      |        |          | 357          |        |          | 303          |
| In faeces      |        |          | 94           |        |          | 84           |
| In urine       |        |          | 263          |        |          | 219          |
| In urine (%)   |        |          | 73.7         |        |          | 72.4         |

Results in the Tables A4.3a, A4.3b and A4.3c show that the N excretion in 2005 is much lower than in 1991, mainly because of the lower N content of the feeds. Since the N retention hardly differs between both years there is a much lower N excretion in the urine. The proportion of the percentage N in urine : N in faeces is on average 1.7% unit lower in 2005 compared to 1991.

**Table A4.3c**

*N housekeeping (g) by rearing hens and roosters (100% brown) of laying varieties younger than ca. 18 weeks in battery housing in kg N per animal year (category 300A)*

| Category 300A  | 1991   |          |              | 2005   |          |              |
|----------------|--------|----------|--------------|--------|----------|--------------|
|                | g N/kg | DC-N (%) | N uptake (g) | g N/kg | DC-N (%) | N uptake (g) |
| Start feed     | -      | -        | -            | 26.1   | 80.7     | 24           |
| Rearing feed 1 | 31.3   | 80.7     | 109          | 26.1   | 80.7     | 117          |
| Rearing feed 2 | 31.3   | 79.1     | 402          | 26.1   | 79.1     | 308          |
| Total uptake   |        |          | 510          |        |          | 450          |
| Fixation       |        |          | 116          |        |          | 127          |
| Excretion      |        |          | 394          |        |          | 322          |
| In faeces      |        |          | 105          |        |          | 92           |

| In urine (%)   |        |          | 73.4         |        |          | 71.6         |

## A4.3 Rearing hens and roosters of laying varieties younger than ca. 18 weeks in housing other than battery (category 300B)

In Section A4.2 some general remarks are made which are also valid for this section. Also it needs to be mentioned that to make an estimation of the technical results in this housing systems research data of free range housing is used.

### A4.3.1 Starting points

In the alternative housing (free range) almost completely middle heavy hens are used (Cijferinfo Pluimveesector 99/11; PVE, 1999). Also the data from research concerns these hens. As a result it is chosen to take only middle heavy hens for this category, both for 2002 and 2006.

The start weight of the rearing hens for both 2000 and 2005 is set to 35 g (Reuvekamp, 2004). The end weight of this category is for both 2000 and 2005 1,520 g (Managementgids Isabrown, 2004);

Vermeij, 2005; Hendrix-Poultry, 2005). The length of the rearing period is 119 days (KWIN-V, 2000; 2005). Per rearing period for 2000 the feed uptake per delivered hen is 5.9 kg (per middle heavy hen present 5.8 kg) (KWIN-V, 2000). This results in a feed conversion of 4.20. The ratio between uptake of rearing feed 1 and 2 is 20:80. For 2005 the feed conversion per rearing period per animal present for middle heavy laying hens is 6.0 kg and the feed conversion is 3.96. The ratio between uptake of start feed, rearing feed 1 and 2 in 2005 is 5:26:69. The loss of animals for 2000 is 4.0% and for 2005 also 4.0%. The percentage animals lost is only used for the conversion of delivered hen to average present hen.

In 2000 the rearing feeds contain on average 28.6 g N/kg, while these feeds in 2005 contain on average 26.1 g N/kg. The digestibility of the rearing feeds in 2000 is derived from the feed compositions of Van Niekerk and Reuvekamp (1994; 1995a and 1995b). For rearing feed 1 there were three observations and for rearing feed 2 the same. For the start feed the digestibility of rearing feed 1 is taken. Because the lack of data on rearing feeds in 2005 the same digestibilities as in 2000 are used.

#### *A4.3.2 Results rearing hens and roosters of laying varieties younger than ca. 18 weeks in housing other than battery*

In Table A4.4 is based on abovementioned starting points an overview given of the N uptake and excretion for rearing hens and roosters of laying varieties younger than ca. 18 weeks in non-battery housing systems. The calculated excretion is expressed per animal year (1 animal that is present the whole year). With this the figure differs from usual parameters within the sector.

**Table A4.4**

*N housekeeping (g) by rearing hens and roosters (100% brown) of laying varieties younger than ca. 18 weeks in non-battery housing in kg N per animal year (category 300B)*

| Category 300B  | 2000   |          |              | 2005   |          |              |
|----------------|--------|----------|--------------|--------|----------|--------------|
|                | g N/kg | DC-N (%) | N uptake (g) | g N/kg | DC-N (%) | N uptake (g) |
| Start feed     | -      | -        | -            | 26.1   | 80.7     | 24           |
| Rearing feed 1 | 28.6   | 80.7     | 99           | 26.1   | 80.7     | 121          |
| Rearing feed 2 | 28.6   | 79.1     | 408          | 26.1   | 79.1     | 326          |
| Total uptake   |        |          | 507          |        |          | 471          |
| Fixation       |        |          | 119          |        |          | 128          |
| Excretion      |        |          | 388          |        |          | 343          |
| In faeces      |        |          | 104          |        |          | 96           |
| In urine       |        |          | 284          |        |          | 247          |
| In urine (%)   |        |          | 73.1         |        |          | 72.0         |

Results in Table A4.4 show that the N excretion in 2005 is somewhat lower than in 2000, mostly due to the somewhat lower N content of the feeds. Since the N retention hardly differs between both years the N excretion in the urine is lower. The division of the percentage N in urine : N in faeces becomes 1.1% unit lower in 2005 compared to 2000.

#### **A4.4 Hens and roosters of laying varieties ca. 18 weeks and older in battery housing (category 301A)**

In this section the calculations for hens in battery systems are examined further. Here also the differences are calculated if only white leghorns or brown laying hens are kept in a battery system.

##### *A4.4.1 Starting points*

The start weight of the middle heavy and white laying hens for 1993 is 1,420 respectively 1,215 g (KWIN-V, 1993). For 2005 these weights are 1,520 respectively 1,285 g. The end weight of this category at the end of the laying period is in 1993 for middle heavy and white laying hens 2,050 respectively 1,750 g (KWIN-V, 1993). For 2005 these weights are 1,800 respectively 1,600 g. The

length of the laying period is 417 days (399 days actual laying period, 18 days rearing) (KWIN-V, 1993). The division over middle heavy and white laying hens in battery housing is 56:44 (WUM, 1994) and for 2005 50:50 is taken (Cijferinfo Pluimveesector 99/11; PVE, 1999).

The feed uptake of the middle heavy and white laying hens amounts 90 respectively 85 g/day during rearing and 117.5 respectively 110 g/day during the actual laying period for 1993, and for 2005 110 respectively 109.5 g/day is taken (KWIN-V 1993 respectively 2005). Per round the feed uptake in 1993 is on average 42.6 kg per hen present. In 1993 per hen laid on 19.9 (middle heavy) or 20.4 kg (white laying hen) eggs are produced. In this is calculated with another 5 eggs produced during rearing with the same egg weight. The average feed conversion is 2.23 (KWIN-V, 1993), which is based on feed uptake from 20 weeks on and egg production from 17 weeks.

Per round the feed uptake in 2005 is on average 41.1 kg per hen present. In 2005 per hen laid on 20.5 (middle heavy) or 22.3 kg (white laying hen) eggs are produced. In this is calculated with another 5 eggs produced during rearing with the same egg weight. The average feed conversion is 2.02 (KWIN-V, 2005), which is based on feed uptake from 20 weeks on and egg production from 17 weeks.

The loss of animals amounts to 6.3 and 7.3% for middle heavy and white laying hens in 1993 and for 2005 the same values have been taken. The percentage of animals lost is only used for the conversion of delivered hen to average present hen.

The start and laying feeds contain in 1993 on average 29.1 g N/kg (WUM, 1994). For 2005 the average N content in the start and laying feeds was 24.9 g N/kg (Van Bruggen, 2007). The ratio between the laying feeds 1, 2 and 3 over the laying period is 40:40:20, both for 1993 and 2005. There are also businesses where laying feed 2 is used to the end of the laying period instead of switching to laying feed 3. In the calculations this is not taken into account.

The digestibility of the laying hen feeds in 1993 is derived from the feed compositions of Van Niekerk and Reuvekamp (1994; 1995a; 1995b; 1997) and Emous *et al.* (1999). For laying feed 1 there were six observations with an average N digestibility of 84.1%. Of laying feed 2 there were six observations too with an average N digestibility of 83.8%, while for laying feed 3 there were four observations with an average N digestibility of 83.2%. For 2005 we had the disposal of data on laying feed 1 of the first half year of 2006. The average N digestibility was 84.5%. For laying feed 2 the same N digestibility was taken and for laying feed 3 an N digestibility of 84.0% was taken. The N digestibility of the start feed is set equal to that of the laying feed 2.

#### *A4.4.2 Results hens and roosters of laying varieties ca. 18 weeks and older in battery housing*

In Tables A4.5a, A4.5b and A4.5c is based on abovementioned starting points an overview given of the N excretion for hens and roosters of laying varieties of ca. 18 weeks and older in batteries.

**Table A4.5a**

*N housekeeping (g) by hens and roosters of laying varieties of ca. 18 weeks and older in battery housing (ca. 50% white) in kg N per animal year (category 301A)*

| Category 301A | 1993   |          |              | 2005   |          |              |
|---------------|--------|----------|--------------|--------|----------|--------------|
|               | g N/kg | DC-N (%) | N uptake (g) | g N/kg | DC-N (%) | N uptake (g) |
| Rearing feed  | 29.1   | 79.1     | 39           | 27.0   | 79.1     | 40           |
| Laying feed 1 | 29.1   | 84.1     | 464          | 24.9   | 84.5     | 380          |
| Laying feed 2 | 29.1   | 83.8     | 464          | 24.9   | 84.5     | 380          |
| Laying feed 3 | 29.1   | 83.2     | 232          | 24.9   | 84.0     | 190          |
| Total uptake  |        |          | 1,200        |        |          | 990          |

| Total uptake  |        |          | 1,155        |        |          | 986          |
| Fixation      |        |          | 345          |        |          | 365          |
| Excretion     |        |          | 810          |        |          | 620          |
| In faeces     |        |          | 189          |        |          | 156          |
| In urine      |        |          | 622          |        |          | 465          |
| In urine (%)  |        |          | 76.7         |        |          | 74.9         |

**Table A4.5c**

*N housekeeping (g) by hens and roosters of laying varieties of ca. 18 weeks and older in battery housing (100% middle heavy; brown) in kg N per animal year (category 301A)*

| Category 301A | 1993   |          |              | 2005   |          |              |
|---------------|--------|----------|--------------|--------|----------|--------------|
|               | g N/kg | DC-N (%) | N uptake (g) | g N/kg | DC-N (%) | N uptake (g) |
| Rearing feed  | 29.1   | 79.1     | 42           | 27.0   | 79.1     | 44           |
| Laying feed 1 | 29.1   | 84.1     | 477          | 24.9   | 84.5     | 380          |
| Laying feed 2 | 29.1   | 83.8     | 477          | 24.9   | 84.5     | 380          |
| Laying feed 3 | 29.1   | 83.2     | 239          | 24.9   | 84.0     | 190          |
| Total uptake  |        |          | 1,235        |        |          | 994          |
| Fixation      |        |          | 354          |        |          | 358          |
| Excretion     |        |          | 881          |        |          | 636          |
| In faeces     |        |          | 202          |        |          | 157          |
| In urine      |        |          | 679          |        |          | 479          |
| In urine (%)  |        |          | 77.1         |        |          | 75.2         |

The results in Table A4.5a are for businesses with a division of ca. 50% white and 50% middle heavy (brown) laying hens; those in Table A4.5b and A4.5c are for businesses with 100% white respectively 100% brown laying hens. The calculated excretion is expressed in g N per animal year (1 animal that is present the whole year). As such this figure differs from the usual parameters in the sector.

#### *A4.4.3 Discussion laying hens in battery housing*

Tables A4.5a, A4.5b and A4.5c show that differences in total N excretion between the various laying varieties do exist, but that there are hardly differences in the share TAN in the excreta. Compared to 1993 the share TAN in the excreta decreased somewhat with on average 1.8% unit. Examined is also what the effect on the excretion of N in faeces and urine is, if the N digestibility is 1% unit higher or lower. Table A4.6 gives the results of this.

**Table A4.6**

*N uptake and N excretion (g) by hens and roosters of laying varieties of ca. 18 weeks and older in battery housing (ca. 50% white) in kg N per animal year (category 301A)*

| In faeces     | 208                     | 196                       | 184                      | 166                     | 156                       | 147                      |
| In urine      | 642                     | 654                       | 666                      | 462                     | 472                       | 481                      |
| In urine (%)  | 75.5                    | 76.9                      | 78.3                     | 73.5                    | 75.1                      | 76.7                     |

From Table A4.6 follows that in the dependability of the differences in the N digestibility there are no large shifts in the relative N excretion through the faeces and urine; with a 2% unit difference in N digestibility the relative share in the urine increases with ca. 3% units.

## A4.5 Hens and roosters of laying varieties ca. 18 weeks and older in housing other than battery (category 301B)

In Section A4.4 some general remarks have been described that also concern this section. Also needs to be mentioned that in estimating the technical results in this housing systems research data of free range housing has been used. In this two types occur, with and without outside access. According to CBS (2004) the number of animals is divided equally over both systems and the technical results over both systems are averages (KWIV-V, 1998; 2005).

### A4.5.1 Starting points for 1998 and 2005

In the alternative housing (free range) almost completely middle heavy hens are used (Cijferinfo Pluimveesector 99/11; PVE, 1999). Also the data from research concern these hens. Therefore it has been chosen to take only the middle heavy hens for this category, both for 1998 as 2005.

The start weight of the middle heavy laying hens for 1998 and 2005 is 1,470 respectively 1,520 g (KWIV-V, 1998; 2005). The end weight of this category at the end of the laying period for 1998 and 2005 is 1,900 respectively 1,800 g (KWIV-V, 1998; 2005). In 1998 the length of the laying period is 401 days (380 days actually laying period, 21 days rearing) and in 2005 that is 406 (385 actual laying period, 21 days rearing (KWIV-V, 1998; 2005).

The feed uptake is 97.5 g/day during the rearing and 119 g/day during the actual laying period (KWIV-V, 1998), while in 2005 the uptakes are 100 respectively 121 g/day (KWIV-V, 2005). Per round the feed uptake for 1998 is on average 49.6 kg per hen present and 20.28 kg eggs are produced. This production takes place at an average feed conversion of 2.29. For 2005 the feed uptake is on average 48.7 kg per hen present and the egg production 20.19 kg, resulting in an average feed conversion of 2.25. The loss of animals amounts to 8.3% for 1998 and 9.3% for 2005. The percentage loss of animals is only used for the conversion of delivered hen to average hen present.

The start and laying feeds in 1998 contain on average 26.4 g N/kg (Tamminga *et al.*, 2000). For 2005 the average N content in the start and laying feeds was 24.9 g N/kg (Van Bruggen, 2007). The ratio between the laying feeds 1, 2 and 3 over the laying period is 40:40:20, both for 1993 and 2005. There are also businesses where laying feed 2 is given to the end of the laying period instead of switching to laying feed 3. In the calculations this is not considered.

The digestibility of the laying hen feeds in 1998 is derived from the feed compositions of Van Niekerk and Reuvekamp (1994; 1995a; 1995b; 1997) and Emous *et al.* (1999). For laying feed 1 there were six observations with an average N digestibility of 84.1%. Of laying feed 2 there were also six observations with an average N digestibility of 83.8%, while for laying feed 3 there were four observation with an average N digestibility of 83.2%. For 2005 we had the disposal of data on laying feed 1 of the first half year of 2006. The average N digestibility was 84.5%. For laying feed 2 the same N digestibility as of laying feed 1 is taken and for laying feed 3 84.0% is taken. The N digestibility of the start feed is set equal to that of the rearing feed 2.

#### A4.5.2 Results hens and roosters of laying varieties ca. 18 weeks and older in housing other than battery

In Table A4.7 is based on abovementioned starting points an overview given of the N excretion for hens and roosters of laying varieties of ca. 18 weeks and older in housing other than batteries. The calculated excretion is expressed in g N per animal year (1 animal that is present the whole year). In this the figure differs from usual parameters in the sector.

Table A4.7

*N uptake and excretion (g) by hens and roosters of brown laying varieties ca. 18 weeks and older in housing other than batteries in kg N per animal year (category 301B)*

| Category 301B | 1998    |        |          | 2005  |         |        |          |       |
|---------------|---------|--------|----------|-------|---------|--------|----------|-------|
|               | kg feed | g N/kg | DC-N (%) | kg N  | kg feed | g N/kg | DC-N (%) | kg N  |
| Rearing feed  | 1.8     | 28.6   | 79.1     | 51    | 1.9     | 27.0   | 79.1     | 51    |
| Laying feed 1 | 16.5    | 26.4   | 83.1     | 436   | 16.8    | 24.9   | 84.5     | 417   |
| Laying feed 2 | 16.5    | 26.4   | 82.8     | 436   | 16.8    | 24.9   | 84.5     | 417   |
| Laying feed 3 | 8.2     | 26.4   | 82.2     | 218   | 8.4     | 24.9   | 84.5     | 209   |
| Total         | 43.0    |        |          | 1,140 | 43.8    |        |          | 1,094 |
| Fixation      |         |        |          | 348   |         |        |          | 357   |
| Excretion     |         |        |          | 792   |         |        |          | 736   |
| In faeces     |         |        |          | 187   |         |        |          | 173   |
| In urine      |         |        |          | 605   |         |        |          | 563   |
| In urine (%)  |         |        |          | 76.4  |         |        |          | 76.5  |

From Table A4.7 follows that the N excretion from 1998 to 2005 decreased somewhat, but that there is no difference in the share TAN in the excreta.

## A4.6 Rearing hens and roosters of meat varieties 0 to 19 weeks (category 310)

Category 310 concerns the young parent animals for the broiler sector. Different from the laying sector this is a clearly distinguished category. Differences between hens and roosters have been taken into account. Conversion of parameters took place because in the manure legislation both the hens and roosters are counted, while parameters in some cases are expressed per hen.

### A4.6.1 Starting points for 2000 and 2005

The start weight of the rearing parent animals (the chicks) is for both 2000 and 2005 set to 42 g (Van Middelkoop, 2000). The end weight of this category at ca. 19 weeks of age is for roosters and hens in 2000 2,750 respectively 2,000 g (Ross, 2004) and for 2005 the same weights are taken. The length of the rearing period is for 2000 and 2005 calculated to 126 days (KWIN-V, 2000; 2005). The number of roosters at lay on is 15%. On average there are 14.0% roosters per reared hen (KWIN-V, 2000; 2005). At the end of the rearing period selection of the roosters takes place. At lay on for the laying

period 10% roosters are deployed. Per rearing period is for 2000 the feed uptake of rearing feed 1 and 2 per hen delivered 2.0 respectively 6.5 kg and per average hen present 1.68 respectively 5.47 kg, resulting in an average feed conversion of 3.49. For 2005 the same values are taken.

The loss of animals in 2000 amounts to 7.0 and 14.0% for hens and roosters and also for 2005. The percentage animals lost is only used for the conversion of delivered hen to average present animal.

The rearing feed contains in 2000 on average 28.3 g N/kg (Tamminga *et al.*, 2000) and in 2005 the average N content of the start and rearing feed is 26.1 g/kg (Van Bruggen, 2007). These contents are copied from those of rearing laying hens, since no data was available for the rearing of broiler parents. The digestibility of the rearing feeds in 2000 is derived from the feed compositions of Van der Haar and Meijerhof (1996) and of a feed supplier. For rearing feed 1 there were two observations (average 80.8%) and for rearing feed 2 seven observations (average 80.7%). For the start feed is based on information from a feed supplier an N digestibility of 84.2% taken. For the rearing feeds 1 and 2 is an average N digestibility taken of 80.7%. Since data on rearing feeds in 2005 are lacking the same digestibilities as in 2000 are used.

#### A4.6.2 Results rearing hens and roosters of meat varieties 0 to 19 weeks

In Table A4.8 is based on abovementioned starting points an overview given of the N excretion for rearing hens and roosters of meat varieties 0 to 19 weeks. The calculated excretion is expressed in kg N per animal year (1 animal that is present the whole year). In this the figure differs from usual parameters in the sector.

**Table A4.8**

*N uptake and excretion (g) by rearing hens and roosters of meat varieties 0 to 19 weeks in kg N per animal year (category 310)*

| Category 310       | 2000   |          |              | 2005   |          |              |
|--------------------|--------|----------|--------------|--------|----------|--------------|
|                    | g N/kg | DC-N (%) | N uptake (g) | g N/kg | DC-N (%) | N uptake (g) |
| Rearing feed start | -      | -        | -            | 31.0   | 84.2     | 38           |
| Rearing feed 1     | 28.6   | 80.8     | 140          | 28.4   | 80.8     | 104          |
| Rearing feed 2     | 28.6   | 80.8     | 453          | 25.2   | 80.8     | 400          |
| Total uptake       |        |          | 593          |        |          | 541          |
| Fixation           |        |          | 200          |        |          | 200          |
| Excretion          |        |          | 393          |        |          | 342          |
| In faeces          |        |          | 114          |        |          | 99           |
| In urine           |        |          | 280          |        |          | 242          |
| In urine (%)       |        |          | 71.1         |        |          | 71.0         |

From Table A4.8 follows that the N excretion decreased somewhat from 2000 to 2005, but that there is no difference in the share TAN in the excreta.

## A4.7 Parents of meat varieties ca. 19 weeks and older (category 311)

Category 311 concerns the parent animals for the broiler sector. Different from the laying sector this is a clearly distinguished category. Differences between hens and roosters are taken into account. Conversion of parameters took place because in the manure legislation both the hens and the roosters are counted, while parameters in some cases are expressed per hen.

### A4.7.1 Starting points

The start weight of the hens respectively roosters for 1996 is 1,900 respectively 2,600 g and for 2005 2,000 respectively 2,750 g (Ross, 2004). The end weight of this category at the end of the production period is for hens and roosters for 1996 3,600 respectively 4,800 g and for 2005 3,700 respectively 4,800 g (KWIN-V, 1996; 2005). The length of the production cycle is for 1998 and 2006 calculated to 346 respectively 343 days (KWIN-V, 1996; 2005).

Goal for both 1996 as for 2005 is to have 10% roosters at the start of the laying period. Over the whole period on average 95.51 hens and 8.44 roosters are present. Per laying round is for 1996 the feed uptake on average 3.0 kg pre laying feed and 45.0 kg breeding brood feed per laid on hen (2.9 kg respectively 43.3 kg per average animal present) and 148 brood eggs and 10 consumption eggs of on average 62 grams apiece are produced. This results in 9.27 kg eggs per average present animal. For 2005 the feed uptake per round is on average 3.30 kg pre laying feed and 44.7 kg breeding brood feed per laid on hen (3.20 kg respectively 43.0 kg per average animal present) and 150 brood eggs and 10 consumption eggs of on average 62 grams are produced. This results in 9.54 kg eggs per average animal present. The loss of animals amounts for 1996 to 1.0 respectively 3.5% for hens and roosters during rearing and 10.0 respectively 35.0% during the laying period. For 2005 the percentages loss of animals during rearing are 1.0 respectively 3.6 and 10.0 respectively 35.0% during the laying period. The percentage animals lost is only used for the conversion of delivered hen to average present animal.

The N content in the pre laying feed and the breeding brood feed for 1996 is calculated by taking the average content of 1992 (WUM, 1994) and that of Tamminga *et al.* (2000). The pre laying feed then contains 31.0 g N/kg and the breeding brood feed 27.8 g N/kg. In 2005 the pre laying feed, breeding brood feed 1 and 2 contained respectively 25.2, 24.3 and 24.2 g N/kg (Van Bruggen, 2007). Of the N digestibility of the feeds in 1996 no data are available. For 2005 for the pre laying feed the N digestibility of the rearing feed 2 (80.8%) was taken. Based on data of a composite feed manufacturer beginning 2008 an N digestibility of the breeding brood feed 1 and 2 of 83.2 respectively 82.3% was calculated. These digestibilities are also taken for the feeds of 1996.

### A4.7.2 Results hens and roosters of meat varieties from ca. 19 weeks and older

In Table A4.9 is based on abovementioned starting points an overview given of the N uptake and excretion for hens and roosters of meat varieties from ca. 19 weeks and older. The calculated excretion is expressed in kg N per animal year (1 animal that is present the whole year). In this the figure differs from usual parameters in the sector.

Table A4.9

*N housekeeping (g) by hens and roosters of meat varieties ca. 19 weeks and older in kg N per animal year (category 311)*

| Category 311          | 1996   |          |              | 2005   |          |              |
|-----------------------|--------|----------|--------------|--------|----------|--------------|
|                       | g N/kg | DC-N (%) | N uptake (g) | g N/kg | DC-N (%) | N uptake (g) |
| Start feed            | 31.0   | 80.8     | 103          | 25.2   | 80.8     | 92           |
| Breeding brood feed 1 | 27.8   | 83.2     | 614          | 24.3   | 83.2     | 538          |
| Breeding brood feed 2 | 27.8   | 82.3     | 768          | 24.2   | 82.3     | 662          |
| Total uptake          |        |          | 1,484        |        |          | 1,293        |
| Fixation              |        |          | 258          |        |          | 262          |
| Excretion             |        |          | 1,227        |        |          | 1,030        |
| In faeces             |        |          | 259          |        |          | 225          |
| In urine              |        |          | 968          |        |          | 805          |
| In urine (%)          |        |          | 78.9         |        |          | 78.1         |

From Table A4.9 follows that the N excretion clearly decreases from 1998 to 2005 but that there is hardly difference in the share TAN in the excreta.

## A4.8 Broilers (category 312)

### A4.8.1 Starting points

The start weight of the broilers is for both 2002 and 2006 set to 42 g (Van Middelkoop, 2000). The end weight of broilers at 43 days of age is for 2002 and 2005 2,100 respectively 2,200 g (KWIV-V, 2003; 2007). Per production round is for 2002 the average feed conversion 1.76 (KWIV-V, 2002), resulting in a feed uptake of on average 3.70 kg. For 2005 the production period is 43 days, the feed conversion on average 1.79, resulting in a feed uptake of 3.94 kg (KWIV-V, 2005).

The broiler feed 1, 2 and 3 for 2002 contained 34.6, 32.0 respectively 30.9 g N/kg. The contents for 2005 are 36.0, 34.1 respectively 33.1 g/kg (Van Bruggen, 2007). Of the broiler feed 1 per production round 300 g is taken up, of broiler feed 2 1,500 g and the remainder is broiler feed 3. There are also businesses where besides compound feed also wheat or corn cob mix is fed additionally but in the calculations this is not taken into account.

The digestibility of the broilers is estimated based on various feed compositions of broiler feed 2 at a composite feed manufacturer in the first half of 2006. This was on average 83.9%. Based on discussions with experts it seems reasonable to raise the N digestibility of broiler feed 1 by 2.5% units, so that it becomes 85.4%. Also is assumed that the N digestibility of broiler feed 3 is 0.5% lower than of broiler feed 2, so that the N digestibility then becomes 83.4%. The digestibilities above are taken for 2005. For 2002 based on discussion with some experts an N digestibility for broiler feed 1, 2 and 3 of 85.1, 84.3 respectively 84.3 is taken.

### A4.8.2 Results broilers

In Table A4.10 based on abovementioned assumptions an overview is given of the N excretion for broilers. The calculated excretion is expressed in g N per animal year (1 animal that is present the whole year). In this the figure differs from usual parameters in the sector.

Table A4.10

*N housekeeping (g) by broilers in g N per animal year (category 312)*

| Category 312   | 2002   |      |              | 2005   |      |              |
|----------------|--------|------|--------------|--------|------|--------------|
|                | g N/kg | DC-N | N uptake (g) | g N/kg | DC-N | N uptake (g) |
| Broiler feed 1 | 34.6   | 85.1 | 87           | 36.0   | 85.4 | 92           |
| Broiler feed 2 | 32.0   | 84.3 | 403          | 34.1   | 83.9 | 434          |
| Broiler feed 3 | 30.9   | 84.3 | 492          | 33.1   | 83.4 | 601          |
| Total uptake   |        |      | 981          |        |      | 1,127        |
| Fixation       |        |      | 479          |        |      | 508          |
| Excretion      |        |      | 502          |        |      | 618          |
| In faeces      |        |      | 153          |        |      | 183          |
| In urine       |        |      | 349          |        |      | 435          |
| In urine (%)   |        |      | 69.5         |        |      | 70.4         |

### A4.8.3 Discussion broilers

From Table A4.10 follows that the N excretion from 2002 to 2005 increased clearly, but also that the share TAN in the excreta increased somewhat.

It has been examined what the effect of an N digestibility 1% unit higher or lower is on the excretion in faeces and urine. Table A4.11 gives the results of this.

**Table A4.11**

*N uptake and N excretion (kg) by broilers in g N per animal year (category 312)*

| Category 312 | 2002                    |                           |                          | 2005                    |                           |                          |
|--------------|-------------------------|---------------------------|--------------------------|-------------------------|---------------------------|--------------------------|
|              | DC-N 1<br>unit<br>lower | DC-N<br>starting<br>point | DC-N 1<br>unit<br>higher | DC-N 1<br>unit<br>lower | DC-N<br>starting<br>point | DC-N 1<br>unit<br>higher |
| Total uptake | 981                     | 981                       | 981                      | 1,127                   | 1,127                     | 1,127                    |
| Excretion    | 502                     | 502                       | 502                      | 618                     | 618                       | 618                      |
| In faeces    | 163                     | 153                       | 144                      | 194                     | 183                       | 172                      |
| In urine     | 339                     | 349                       | 359                      | 424                     | 435                       | 446                      |
| In urine (%) | 67.5                    | 69.5                      | 71.4                     | 68.6                    | 70.4                      | 72.2                     |

From Table A4.11 follows that in the dependability of a difference in N digestibility of 2% units the amount N in urine as percentage of the total N excretion yields a difference of ca. 4% units.

## A4.9 General discussion poultry

### *A4.9.1 Reliability contents of and digestibility of N in chicken feeds and effects on the N excretion*

Not for all feeds there is a reliable picture of the correct content of N in feeds for chickens. Often these data are lacking in the various years. Also it is difficult or even not feasible to obtain these contents from compound feed manufacturers. In addition the raw material composition of the feeds is not released by most of the compound feed manufacturers. It is amply known that by whether or not taking up free amino acids in the feeds the N content in the feeds can be lowered, but at the same time it is also possible to take up protein containing raw materials of poorer quality in the feed. Depending on the strategy at the firm both the N content and the N digestibility can vary. It is desirable to collect better underpinned data hereof.

## A4.10 Summary poultry

In Table A4.12 a summary is given of the excretion of N by various chicken categories in the reference year and in 2005 in g/year.

**Table A4.12**

*Overview of the excretion of N and % TAN by various chicken categories in the reference year and 2005 (g/year)*

| Category                      | Number | Ref.<br>year | N in ref.<br>year | % TAN in<br>ref. year | N in<br>2005 | % TAN<br>in 2005 |
|-------------------------------|--------|--------------|-------------------|-----------------------|--------------|------------------|
| Rearing laying hens (battery) | 300A   | 1991         | 389               | 73.5                  | 307          | 71.8             |

| Laying hens (battery)         | 301A   | 1993         | 850               | 76.9                  | 628          | 75.1             |
| Laying hens (ground)          | 301B   | 1998         | 792               | 76.4                  | 736          | 76.5             |
| Rearing broiler parents       | 310    | 2000         | 393               | 71.1                  | 342          | 71.0             |
| Broiler parents               | 311    | 1996         | 1,227             | 78.9                  | 1,030        | 78.1             |
| Broilers                      | 312    | 2002         | 502               | 69.5                  | 618          | 70.4             |

## A4.11 Turkeys

### A4.11.1 General

In Table A4.13 data on the average content of N in the animal product and in Table A4.14 the contents of protein and N and the faecal digestibility of N in the various turkey feeds are shown. The contents in the various turkey feeds in 1998 are derived from Veldkamp (1996) and Veldkamp *et al.* (1999) and in 2005 from Jongbloed and Kemme (2005). Also information was obtained from dr. Veldkamp, turkey specialist of ASG (Veldkamp, 2008).

Table A4.13

*Weights and contents of N in various turkey categories and in turkey eggs*

| Animal category                 | Weight (g)<br>1998 | Weight (g)<br>2005 | Physiological<br>status | N content<br>(g/kg) | Literature<br>contents |
|---------------------------------|--------------------|--------------------|-------------------------|---------------------|------------------------|
| Turkey egg                      | 89                 | 89                 | -                       | 19.4                | WUM, 1994              |

| Turkey feed phase 6 | 1998           | 27.6   | 84.0     | 24.2   | 84.0     |

## A4.12 Turkeys for slaughter (category 210)

To assess various technical results of turkeys for slaughter the data of KWIN are used. Furthermore information given by dr. Veldkamp (2008) has been processed.

### A4.12.1 Starting points for 1998 and for 2005

The start weight of turkeys for slaughter for both 1998 and 2005 is set to 57 g (Veldkamp, 2008). For 1998 the end weight of the roosters and hens on an age of 147 and 116 days (on average 132 days) is 18.50 respectively 9.50 kg (average 14.00 kg). For 2005 the end weight of the roosters respectively hens on an age of 145 respectively 112 days (on average 128 days) is 19.50 respectively 9.80 kg (average 14.60 kg). Per production period is for 1998 the average feed conversion per kg delivered weight 2.63, resulting in a feed uptake of 36.9 kg per round and 99.9 kg per year. For 2005 the average feed conversion is 2.63, resulting in a feed uptake of 38.7 kg per round and 105.7 kg per year. The division of the feed uptake over the various phases is derived from British United Turkeys (2006).

The N contents in the various feeds for turkeys for slaughter are shown in Table A3.15. The N contents in the feeds for the year 1998 are derived from Veldkamp (1996) and Veldkamp *et al.* (1999) and are averages for each phase. The N contents in the various turkey feeds for 2005 are the same as

mentioned by Jongbloed and Kemme (2005). Based on the feed composition according to Veldkamp *et al.* (1999) the digestibility of N in the various feeds for turkeys for slaughter are estimated. The digestibility of N in the distinguished feeds is kept equal for both years (Table A3.15) based on Veldkamp (2008).

#### A4.12.2 Results turkeys for slaughter

In Table A4.15 is based on abovementioned starting points an overview given of the N excretion for turkeys for slaughter. The calculated excretion is expressed in kg N per animal year (1 animal that is present the whole year). In this the figure differs from usual parameters in the sector.

**Table A4.15**

*N housekeeping (kg) by turkeys for slaughter in kg N per animal year (category 210)*

| Category 210        | 1998   |          |              | 2005   |          |              |
|---------------------|--------|----------|--------------|--------|----------|--------------|
|                     | g N/kg | DC-N (%) | N uptake (g) | g N/kg | DC-N (%) | N uptake (g) |
| Start feed          | 45.8   | 85.0     | 53           | 44.7   | 85.0     | 54           |
| Turkey feed phase 2 | 41.4   | 83.6     | 134          | 40.9   | 83.6     | 141          |
| Turkey feed phase 3 | 37.4   | 83.4     | 553          | 35.8   | 83.4     | 561          |
| Turkey feed phase 4 | 31.3   | 83.1     | 767          | 29.6   | 83.1     | 768          |
| Turkey feed phase 5 | 31.3   | 83.1     | 992          | 26.1   | 83.1     | 876          |
| Turkey feed phase 6 | 27.6   | 84.0     | 676          | 24.2   | 84.0     | 625          |
| Total uptake        |        |          | 3,175        |        |          | 3,025        |
| Fixation            |        |          | 1,248        |        |          | 1,321        |
| Excretion           |        |          | 1,927        |        |          | 1,704        |
| In faeces           |        |          | 527          |        |          | 502          |
| In urine            |        |          | 1,400        |        |          | 1,202        |
| In urine (%)        |        |          | 72.6         |        |          | 70.5         |

From the results according to Table A4.15 follows that N excretion has decreased because of the lower N content in the feeds and a higher retention of N. As a result less N is excreted through the urine and share N in urine as percentage of the total N excretion decreased from 72.6 to 70.5%.

# Annex 5 Mineralization and immobilization of nitrogen in manure

*Gerard Velthof (Alterra Wageningen UR)*

Part of the organic matter in manure is easily degradable and will already be broken down in the animal house or storage. During this process, CH<sub>4</sub> and CO<sub>2</sub> and depending on the composition of the manure, also NH<sub>4</sub><sup>+</sup> are formed (mineralization). In manure containing straw (high C/N ratio) part of the NH<sub>4</sub><sup>+</sup> will be fixed (immobilized) as organic N.

The method to calculate NH<sub>3</sub> emission described in this report is based on TAN. As a result, changes in TAN during the storage of manure have to be taken into account.

In the literature, only little data is available on mineralization and immobilization of ammonium in manure storages. This is mainly because these processes are hard to determine through a balance method in manure from which also NH<sub>3</sub> is emitted. Another possibility to determine mineralization is the use of <sup>15</sup>N labeled N, that is added to the ration of the animal or the manure.

In an incubation study of Sommer *et al.* (2007) the N mineralization was low at 10 °C, for both liquid cattle manure as liquid pig manure. The manure has been collected fresh and was stored frozen, until the start of the incubation study. The mineralization increased strongly at increasing temperature. About 80% of the organic N was mineralized at 15-20 °C for 100-200 days. Mineralization was higher in pig manure than in cattle manure.

In an incubation study of Sørensen *et al.* (2003), mineralization of 9-50% of the organic N in liquid cattle manure was found. The fresh manure was incubated at 8 °C for 16 weeks first, and then for 4 weeks at 15 °C.

Processing of data from an incubation study of Velthof *et al.* (2005) shows that the N mineralization of organic N of liquid pig manure at high temperature (90 days at 35 °C) was on average 15%, with a variation of -11 to +30% (depending of the ration). The manure was collected fresh and stored frozen, until the start of the incubation study.

In an incubation study with pig manure to which <sup>15</sup>N labeled urea was added (Beline *et al.*, 1998) the N mineralization was 19% of the organic N during 84 days at 20 °C. The manure was collected from a farm and thus been stored for a while (it is not clear how long the storage period was).

In models used in England and Germany for calculation of ammonia emissions on the national scale the N mineralization is set to 10% of the organic N (with reference to the research of Beline *et al.*, 1998). In the models used by Denmark and Switzerland, mineralization is not (yet) taken into account.

In the methodology described in this report, it is assumed that 10% of the organic N in liquid manure stored in the animal house mineralizes. This might be a conservative assumption. Given the uncertainties only mineralization in the animal houses is calculated and not in the outside storage. Also in the outside storage mineralization can occur, but this is possibly lower since the easily degradable organic N will mineralize quickly after excretion in the animal house.

For solid manure it is assumed that there is no net mineralization and immobilization. It is recommended to conduct further research into (net) mineralization in liquid cattle and pig manure, since this has an effect on calculated NH<sub>3</sub> emissions from the animal house, manure storage and manure application.

---

# Annex 6 Emission factors for ammonia from animal housing of cattle

In this annex the emission factors in kg NH<sub>3</sub> per animal place are given that form the basis for the calculation of emission factors with respect to the TAN excretion (Section 4.3.1).

## Dairy cows

In the calculation model NEMA the N excretion is divided over the winter and grazing period with corresponding TAN contents. During the grazing period dairy cows spend part of their time in the animal house and another part on pasture land. The N excretion of the grazing period is therefore split into excretion in the animal house and during grazing. To connect to the N excretion the year round emission factors are split into factors for the winter period and for time spent in the animal house in unlimited (day and night) and limited (daytime) grazing, see also Van Bruggen *et al.*, 2011 (Section 5.4.2).

In Ogink *et al.* (2014) a current emission factor of 13.0 kg NH<sub>3</sub> per animal place is calculated for dairy cattle kept continuously indoors in traditional housing systems. These are cubicle housings with slatted floors as walking area and manure storage below the grates (Rav-code A1.100). Decrease in emissions per hour of grazing is determined to be 2.61%. On a yearly basis the procentual emission reduction then is:

$$2.61\% \times (\text{number of grazing hours per day}) \times (\text{number of grazing days})/365 \quad (\text{A6.1})$$

Based on the reference value of 13.0 kg NH<sub>3</sub> per animal place and above formula, in Table A6.1 emission factors are calculated for the winter period and for the time spent in the animal house during the grazing period for each grazing system. Ogink *et al.* (2014) do not split the year round emission. The calculation of the emission reduction by grazing of the working group NEMA differs somewhat from the calculation in Ogink *et al.* (2014). The working group NEMA takes the average number of grazing days in the years emission measurements took place (2007-2012) as the starting point, where in Ogink *et al.* (2014) the length of the grazing period of 2012 and a weighted average number of hours grazing per day are used.

In the calculation of the ammonia emission of dairy cattle housings an increase in emission per animal place from 11.0 kg NH<sub>3</sub> in 2001 to 13.0 kg in the measurement period 2007-2012 is assumed.

The emission factors for low emission housing systems (low emission techniques in a traditional housing setup) are adjusted based on the proportion between the new and old factor for traditional housing according to Ogink *et al.* (2014). In continuously indoors this means multiplication with factor 13.0/11.0 and in limited grazing multiplication with factor 11.74/9.5.

The average emission factor for low emission cubicle housing is derived from information in environmental permits (Van Bruggen *et al.*, 2011 p. 25 and Van Bruggen *et al.*, 2013; Annex 1). The new year round emission factor for low emission housing with limited grazing then becomes:  $(11.74/9.5) \times 7.5 = 9.27$  and for continuously indoors:  $(13.0/11.0) \times 8.8 = 10.40$ . In Van Bruggen *et al.* (2011) the year round emission factor is divided over winter and grazing period based on the proportion between winter and grazing period in traditional housing with limited grazing. This means that in low emission cubicle housing 5.5 kg NH<sub>3</sub> is emitted during the winter period:  $(6.98/11.74) \times 9.27$ . For low emission cubicle housing with unlimited grazing no year round emission can be calculated based on environmental permits. The emission from animal housing during the grazing period with unlimited grazing is therefore calculated with the proportion between grazing and the animal house in traditional housing with unlimited grazing (2.88/6.02).

In Table A6.2 an overview is given of the emission factors for low emission housing of dairy cattle. Compared to Van Bruggen *et al.* (2014) the emission factor of tie-stall housing has also been adjusted in the way proposed by Ogink *et al.* (2014):  $4.3 \times (13.0/11.0)$ .

**Table A6.2**

*Emission factors for low emission dairy housing (kg NH<sub>3</sub>/animal place)*

| Grazing system                      |  |   |                                     |
| continuously indoors                | 5.51                                   | 4.89                                    | 10.40                               |
| limited grazing                     | 5.51                                   | 3.76                                    | 9.27                                |
| unlimited grazing                   | 5.51                                   | 2.34                                    | 7.85                                |
| <b>Tie-stall with liquid manure</b> | 3.02                                   | 2.06                                    | 5.08                                |

The emission factors in Tables A6.1 and A6.2 are converted into emission factors in per cent of the TAN excretion in the winter and grazing periods using the method described in Section 4.3.1.

**Other cattle excluding veal calves**

Ogink *et al.* (2014) propose to calculate NH<sub>3</sub> emission factors per animal place for other cattle categories with the formula:

$$(\text{TAN excretion in the animal house of animal category}) / (\text{TAN excretion in the animal house dairy cattle}) \times 13.0 \tag{A6.2}$$

This therefore means that the emission factor for traditional housing compared to the TAN excretion for all cattle categories is equal. In NEMA emission factors are calculated compared to the TAN excretion including 10% mineralization of organic N. Ogink *et al.* (2014) however do not consider the 10% mineralization of organic N and as a result emission factors calculated with above formula differ somewhat because the percentage organic N differs between cattle categories. To prevent these differences the calculation in Ogink *et al.* (2014) is applied on TAN excretion including 10% mineralization of organic N.

In the calculation of the ammonia emission of dairy cattle housings an increase in emission per animal place from 11.0 kg NH<sub>3</sub> in 2001 to 13.0 kg in the measurement period 2007-2012 is assumed. By relating the emission factor for other cattle to that of dairy cows this means that for other cattle a comparable development has taken place in which the emission has increased over time.

In Table A6.3 the calculation of the emission factors is presented.

**Table A6.3**

*Emission factors NH<sub>3</sub>-N for other cattle categories in % of TAN excretion (including 10% net mineralization)*

|   | 1990-2001 | 2002  | 2003  | 2004  | 2005  | 2006  | from 2007 on |
|---|-----------|-------|-------|-------|-------|-------|--------------|
| Emission factor compared to TAN excretion | 10.12     | 10.55 | 10.97 | 11.39 | 11.82 | 12.24 | 12.67        |

For the different cattle categories is based on the TAN excretion in the 2007-2012 period and the emission factors in Table A6.3, the subsequent emission calculated in kg NH<sub>3</sub> per animal place. This calculated emission is compared to the emission factor in the Rav.

### Meat calves

In Groenestein *et al.* (2014) emission factors for meat calves are reconsidered in which separate emission factors are proposed for white veal calves and rosé veal calves. The factor for both categories was 2.5 kg NH<sub>3</sub> per animal place in the reference year 1998 with an occupancy rate of 0.93. The husbandry of meat calves and management thereof have evolved such that the available older measurement series are no longer representative of current practice. The new emission factors are derived from the emission factor of dairy cows (13.0 kg NH<sub>3</sub>/animal place) in which differences in TAN excretion, size of emitting surfaces (Groenestein *et al.*, 2014) and the contribution of the grates and slurry pit to the emission of the animal house are taken into account. This method therefore differs from the method used in determining the emission factors for other cattle in above text. The new reference year is 2012.

The new factors are 3.1 and 3.7 kg NH<sub>3</sub> per animal place respectively for white veal calves and rosé veal calves, at an occupancy rate of 0.93 for white veal calves and 0.96 for rosé veal calves.

The emission factor for NH<sub>3</sub>-N compared to the TAN excretion of white veal calves, including 10% mineralization of organic N, amounts to 25.8% in the reference year 1998. As a result of the higher TAN excretion in the new reference year 2012 belonging to the new emission factor per animal place the emission factor remains 25.8%.

For rosé veal calves the emission factor compared to the TAN excretion, including 10% mineralization of organic N, is 11.9% in the reference year 1998. The revised emission of 3.7 kg NH<sub>3</sub> per animal place yields an emission factor of 20.6% compared to the TAN excretion in the reference year 2012.

Between 1998 and 2012 the emission factor is gradually increased through interpolation. The occupancy rate is increased from 0.93 to 0.96.

Since between the reference years 1998 and 2012 a gradual change in management took place, the emission factor is being interpolated. For meat calves two different methods for interpolation between 1998 and 2012 are possible: interpolation of the proposed Rav factor or interpolation of the emission factor compared to the TAN excretion. Interpolation of the proposed Rav factor means for white veal calves a gradual increase from 2.5 kg NH<sub>3</sub> to 3.1 kg NH<sub>3</sub> and for rosé veal calves an increase from 2.5 to 3.7 kg NH<sub>3</sub> per animal place. In the second method of interpolation the emission factor compared to the TAN excretion is gradually adjusted. For white veal calves this means the emission factor remains constant (25.8%) and for rosé veal calves a gradual increase from 11.9 to 20.5%.

In the table below the difference between both methods is given. Choice was made to interpolate the emission factor on the basis of net TAN excretion (bold). With interpolation of the proposed Rav factor yearly fluctuations in the emission factor compared to the TAN excretion would occur, because TAN excretion also have yearly fluctuations. The latter is not logical since one would expect the emission factor compared to the TAN excretion to be constant or gradually changing because of changing management, but not to fluctuate yearly.

**Table A6.5**

*Emission factors for NH<sub>3</sub> in % of TAN excretion (including 10% net mineralization)*

The emission factor for low emission housing was previously established to be 0.60 kg NH<sub>3</sub> per animal place based on the shares of various types of air scrubbers in the environmental permits of provinces. This meant an average emission reduction of 76% compared to the regular emission factor of 2.5 kg NH<sub>3</sub> per animal place. With the same percentage reduction the emission factor for low emission housing in white veal calves becomes 0.24 x 3.1 = 0.74 kg NH<sub>3</sub> per animal place and in rosé veal calves 0.24 x 3.7 = 0.89 kg NH<sub>3</sub> per animal place.

# Annex 7 Emission factors for ammonia from animal housing of pigs

In this annex the emission factors in kg NH<sub>3</sub> per animal place are given that form the basis for the calculation of emission factors relative to the TAN excretion (Section 4.3.1).

**Table A7.1**

*Emission factors for traditional pig housing (kg NH<sub>3</sub> per animal place)*

|   | kg NH <sub>3</sub> / animal place |
|---|-----------------------------------|
| Sows with piglets   | 8.3                               |
| Open and sows in pig  | 4.2                               |
| Weaned piglets  | 0.60                              |
| Fattening and rearing pigs  |                                   |
| Slurry pit under complete animal place, pen surface 0.8 m <sup>2</sup> /animal place    | 5.0                               |
| Slurry pit under complete animal place, pen surface 1.0 m <sup>2</sup> /animal place    | 6.1                               |
| Slurry pit under part of the animal place, pen surface 0.8 m <sup>2</sup> /animal place | 3.4                               |
| Slurry pit under part of the animal place, pen surface 1.0 m <sup>2</sup> /animal place | 4.0                               |
| Boars for service   | 5.5                               |

# Annex 8 Emission factors for ammonia from animal housing of poultry

In this annex the emission factors in kg NH<sub>3</sub> per animal place are given that form the basis for the calculation of emission factors relative to the TAN excretion (Section 4.3.1).

## Laying hens younger than ca. 18 weeks

In Table A8.1 the housing systems are depicted according to the classification of the Agricultural Census. For some systems that comprise of several subsystems an emission factor is derived using information in environmental permits.

Table A8.1

*Emission factors for laying hens under 18 weeks (kg NH<sub>3</sub> per animal place)*

|   | kg NH <sub>3</sub> per animal place |
|---|-------------------------------------|

| <b>Battery cage with solid manure</b>   |                                     |
| manure belt, forced manure drying 0.2 m <sup>3</sup> /animal/hour                   | 0.020                               |
| manure belt, forced manure drying 0.4 m <sup>3</sup> /animal/hour                   | 0.006                               |
| manure belt, forced manure drying 0.4 m <sup>3</sup> /animal/hour with air scrubber | 0.001                               |
| other battery cage solid manure   | 0.020                               |
| <b>Ground housing without manure aeration</b>                                       | 0.170                               |
| <b>Aviary system</b>  |                                     |
| aviary housing without forced manure drying   | 0.050                               |
| aviary housing with forced manure drying  | see Table A8.2                      |
| ground/aviary housing with air scrubber   | see Table A8.2                      |
| other housing   | see Table A8.2                      |

To the battery cage systems with liquid manure and manure belt also the compact battery is counted with an emission factor of 0.011 kg NH<sub>3</sub>/animal place. The share of this system in environmental permits is negligibly small with 0.1%.

It is not clear which systems have been filled in by businesses under 'other battery cage housing solid manure' in the Agricultural Census of 2008. To the other battery cage systems with solid manure belong the channel animal house (E1.4) and the battery cage system with manure belt aeration and above laying drying tunnel (E1.6). Although it concerns over 7% of the animal places in the Agricultural Census of 2008, systems mentioned hardly occur in the environmental permits. Possibly it concerns businesses with manure belt aeration with the aeration turned off but producing solid manure after all through after drying, and therefore have filled in battery cage housing with solid manure (Ellen, 2010). The emission factor of manure belt with forced manure drying 0.2 m<sup>3</sup> per hour is applied as minimal value.

<sup>1)</sup> Source: environmental permits in province Noord-Brabant on 1-1-2009.

<sup>2)</sup> Source: environmental permits in provinces: Overijssel, Gelderland, Utrecht, Noord-Brabant and Limburg on 1-1-2012.

<sup>3)</sup> Source: environmental permits in provinces: Overijssel, Gelderland, Utrecht, Noord-Brabant and Limburg on 1-1-2014.

<sup>4)</sup> Air scrubber systems are rarely used. Although the emission factor in the Rav applies to ground housing, in the Agricultural Census only aviary housing with air scrubber is counted. In the period after 2010 the calculated emission factor for aviary with air scrubber is applied.

<sup>5)</sup> The composition of this group can vary, depending on the differentiation in animal housing system in the Agricultural Census.

The emission factor in the Rav applies to situations in which the manure is disposed of from the business immediately or stored for a maximum of two weeks in a covered container. In other cases an additional emission factor for post-processing techniques like after drying or other storage applies. The emission factor for the post-processing technique is to be added to the emission factor of the animal housing type. For rearing hens from the environmental permits an average additional emission factor for after drying of 0.005 kg NH<sub>3</sub> is derived.

Although in animals with ground housing in the Agricultural Census in some cases a post-processing technique is applied, this is not accounted for. The Rav does not provide an additional emission factor for post-processing techniques in ground housing.

## Laying hens

In Table A8.3 the housing systems are depicted according to the classification of the Agricultural Census. For some systems that consist of several subsystems an emission factor is derived using information in environmental permits.

|   | see Table A8.4                      |

It is assumed that the enriched cages and colony housing, both with manure belt aeration, have been filled in with battery cage housing with forced manure drying (0.7 m<sup>3</sup>/hour) by businesses.

To the other battery cage systems with solid manure belong the canals animal house (E2.4 and the battery cage system with manure belt aeration and above lying drying tunnel (E2.6). These systems hardly occur. In other battery cage housing with solid manure it concerns most likely businesses with manure belt drying that have switched off the aeration. Possibly part of these businesses have after drying so that they produce solid manure after all (Ellen, 2010). For the share animals with housing type other battery cage solid manure the emission factor of manure belt with forced manure drying 0.042 m<sup>3</sup> per hour is applied as minimal value.

In Table A8.4 the emission factors for systems consisting of several variations are derived. Air scrubbers hardly occur and are not considered further.

<sup>1)</sup> Source: environmental permits in province Noord-Brabant on 1-1-2009.

<sup>2)</sup> Source: environmental permits in provinces: Overijssel, Gelderland, Utrecht, Noord-Brabant and Limburg on 1-1-2012.

<sup>3)</sup> Source: environmental permits in provinces: Overijssel, Gelderland, Utrecht, Noord-Brabant and Limburg on 1-1-2014.

<sup>4)</sup> The composition of this group can vary, depending on the differentiation in animal housing systems in the Agricultural Census.

<sup>5)</sup> Factor put together from several types of air scrubbers.

The emission factor in the Rav applies to situations in which the manure is disposed of immediately from the business or is stored for a period of at most two weeks in a covered container. In other cases an additional emission factor for post-processing techniques like after drying or other storage applies. The emission factor of the post-processing technique is to be added to the emission factor of the animal housing type. Based on information in environmental permits the average additional emission factor for after drying is 0.010 kg NH<sub>3</sub> up to 2010 and for the years after 0.008 kg NH<sub>3</sub> per animal place.

**Broiler parents to ca. 19 weeks**

In Table A8.5 the animal housing systems are depicted according to the classification in the Agricultural Census. For some systems that consist of several subsystems an emission factor is derived using information in environmental permits.

**Table A8.5**

*Emission factors for broiler parents under 19 weeks (kg NH<sub>3</sub> per animal place)*

<sup>2)</sup> Source: environmental permits in provinces: Overijssel, Gelderland, Utrecht, Noord-Brabant and Limburg on 1-1-2012.

<sup>3)</sup> Source: environmental permits in provinces: Overijssel, Gelderland, Utrecht, Noord-Brabant and Limburg on 1-1-2014.

The emission factor in the Rav applies to situations in which the manure is removed from the farm directly or stored for a period of no more than two weeks in a covered container. In the remaining cases an additional emission factor for post-processing techniques like after drying or other storage applies. The emission factor of the post-processing technique has to be added to the emission factor of the housing type. Based on the information in environmental permits the average additional emission factor for after drying amounts to 0.010 kg NH<sub>3</sub> up to 2010 and in the years after 0.008 kg NH<sub>3</sub> per animal place.

### **Broilers**

In Table A8.9 the housing systems are depicted according to the classification of the Agricultural Census. For some systems consisting of several subsystems an emission factor is derived using information in environmental permits.

**Table A8.9**

*Emission factors for broilers (kg NH<sub>3</sub> per animal place)*

### Ducks for slaughter

In ducks for slaughter only traditional housing occurs with an emission factor of 0.210 kg NH<sub>3</sub> per animal place.

### Turkeys for slaughter

In Table A8.11 the housing systems are presented according to the classification of the Agricultural Census. For some systems consisting of several subsystems an emission factor is derived using information of environmental permits.

**Table A8.11**

*Emission factors for turkeys (kg NH<sub>3</sub> per animal place)*

|                      | kg NH <sub>3</sub> per animal place |
|----------------------|-------------------------------------|

# Annex 9 Animal house occupancy fractions

To convert emissions from animal housings in kg NH<sub>3</sub> per animal place to an emission factor in kg NH<sub>3</sub> per animal, the animal house occupancy fractions are needed. For instance an emission of 10.0 kg NH<sub>3</sub> per animal place at an occupancy fraction of 0.9 yields an emission of 10.0/0.9 = 11.1 kg NH<sub>3</sub> per animal entered in the Agricultural Census. Table A9.1 presents reference year, occupancy fraction and period to which these apply (reporting period).

**Table A9.1**

<sup>1)</sup> The reference year is the year or period that corresponds with the year or the period in which the emission factor in kg NH<sub>3</sub> per animal place is taken up in the Rav respectively is measured.

<sup>2)</sup> Per breeding sow present: 0.25 sow with piglets; 0.83 open and sows in pig and 2.8 weaned piglet per breeding sow.

# Annex 10 Manure storage outside the animal house

# Annex 11 Emission factors for calculation direct nitrous oxide emissions from agricultural soils (including grazing)

Marian van Schijndel and Sietske van der Sluis (PBL), 2011

For fertilization with inorganic N-fertilizers and animal manure and for grazing emission factors have been established and applied in the NIR 2011. For an overview see Table 11.1. This memorandum describes the derivation of the (weighted average) emission factors that are applied in the NIR 2011 for the period from 1990 to now in the ER-calculations of direct N<sub>2</sub>O emissions from agricultural soils (including grazing).

Table 11.1

N<sub>2</sub>O-N emission factors (% of the N supply) for calculation of direct N<sub>2</sub>O emissions from agricultural soils and of N<sub>2</sub>O emissions as a result of grazing (based on Velthof and Mosquera, 2011b and Van der Hoek et al., 2007). The marked emission factors are applied since the NIR 2011 (Van der Maas et al., 2011).

(1) Van der Hoek *et al.*, 2007

\* Between brackets the emission factors related to total gross N supply to soil (without deducting NH<sub>3</sub>-N in fertilizing). In the old method the N<sub>2</sub>O-N was calculated based on net N supply to soil, i.e. after deduction of NH<sub>3</sub>-N. In the new method no NH<sub>3</sub>-N deduction is applied anymore. Reason is that this also not happens in the N<sub>2</sub>O measurements in field experiments.

\*\* No (new) data available

## A11.1 Reason revision N<sub>2</sub>O-N emission factors

In 1994 based on laboratory scale experiments country specific emission factors for the direct N<sub>2</sub>O emission from agricultural soils were derived (Kroeze, 1994) for the distinguished sources.

The N<sub>2</sub>O-N emission factor for low emission manure application and surface spreading were respectively 2 and 1% of the N supply to the soil. Thus the emission factor for low emission manure application was compared to surface spreading a factor 2 higher. In 1997 this was summarized in a methodology description (Spakman *et al.*, 1997). For surface spreading the country specific N<sub>2</sub>O-N emission factor was somewhat lower than the IPCC 1996 default (1% versus 1.25% of the N supply).

For the NIR 2005 (Klein Goldewijk *et al.*, 2005) the methodology was developed further and adjusted (Van der Hoek *et al.*, 2007). Amongst others the emission factor for inorganic N-fertilizer is refined based on research of Velthof *et al.*, 1997. This refinement comprised that for a separate category inorganic N-fertilizers (ammonium containing inorganic N-fertilizers that do not contain nitrate) a 50% lower emission factor was applied than used before for all kinds of inorganic N-fertilizer.

Based on field experiments in the Netherlands there seemed to be indications that the N<sub>2</sub>O-N emission factor for low emission manure application was lower than the 2% of the N supply used (Velthof *et al.*, 2003 and Van Groeningen *et al.*, 2004). This led to the question whether low emission manure application in practice indeed had a higher N<sub>2</sub>O-N emission factor than surface spreading. An overview of Dutch and international research results published after the publication of Kroeze in 1994 (Kuikman *et al.*, 2006) offered insufficient reason to adjust and/or further refine the emission factors for low emission manure application and surface spreading (Van der Hoek *et al.*, 2007). In the Netherlands only a very limited number of comparative experiments had been carried out between surface spreading and low emission manure application. These resulted in relatively low emission factors (< 0.1% of the N supply) for both application techniques (Velthof *et al.*, 1997). Results of international comparative field experiments showed that the nitrous oxide emissions for low emission manure application were mostly higher than for surface spreading. However it was not possible to derive long year average N<sub>2</sub>O-N emission factors and adjust these for Dutch circumstances. It was concluded that more research was needed (see also the NIR 2006; Brandes *et al.*, 2006).

---

Between 2007 and 2010 in the Netherlands 2 to 3 year lasting comparative field experiments have been conducted to map the N<sub>2</sub>O emissions for surface spreading and low emission manure application, in which for comparison also the fertilization with inorganic N-fertilizer was researched (Velthof *et al.*, 2010 and Velthof and Mosquera, 2011a). It was found that low emission manure application has higher N<sub>2</sub>O-N emission factors than surface spreading.

The emission factors derived based were lower than the emission factors used for both fertilization techniques, and there were differences in the N<sub>2</sub>O-N emission factors between grassland and arable land and between animal manure and inorganic N-fertilizer. These findings were the incentive to follow-up research. Based on all available Dutch and other NW European measurements of N<sub>2</sub>O emission factors starting from the beginning of the nineties it was recommended to adjust the emission factors for manure application and inorganic N-fertilizer use (Velthof and Mosquera, 2011b). PBL Netherlands Environmental Assessment Agency has reviewed the statistical analysis performed by Velthof and Mosquera on behalf of the Emission Registration (see Annex 2).

## A11.2 Motivation for calculating weighted average emission factors

Table 11.1 distinguishes for animal manure low emission manure application and surface fertilization. Further for animal manure, inorganic N-fertilizer and grazing there are separate emission factors for mineral soils, peat soils, grassland and arable land (see data in italics) as determined by Velthof and Mosquera, 2011b.

### *A11.2.1 Data series N supply to soil*

Based on the historical data for N supply to grassland and arable land (part of the manure and ammonia calculation for the Emission Registration, see for instance Hoogeveen *et al.*, 2010) for four soil types a yearly and multiannual weighted average emission factor can be calculated (Table A11.2 up to Table A11.4, at the end of this Annex). For this the data series of 1990-2005 is used, because the data 2006-2008 show a trend break with the data of 1990-2005. Especially there is a factor 8 to 15 increase in the supply of respectively inorganic N-fertilizer and animal manure to arable land on peat soil. Also there is almost a bisection in the supply of N in manure (through fertilization and grazing) to grassland on peat.

This correlates to specific data becoming available on the cultivation of crops on several soil types through the Agricultural Census since 2006. Up to 2006 this information was not available and crops were allocated to soil types. Grassland was situated on peat soil as much as possible and only in case of too little grassland also arable land was situated on peat soil. The supply of manure to arable land on peat soil was as a result of this limited to << 1% and deemed negligible.

In the assumption that the supply of manure to arable land is negligible, use of the whole data series (1990-2008) leads to a weighted average emission factor that is circa 0.1% lower than in using the data series 1990-2005. For the current emission calculations the data series of 1990-2005 is used to prevent underestimation of the emissions.

From the new information that is available over the period 2006-2008 it turns out that the supply of manure on arable land on peat soil is circa 1 to 2% higher. At this moment it is unknown whether including the supply of manure to arable land on peat leads to significant higher N<sub>2</sub>O emission factors. There is no N<sub>2</sub>O emission factor available for fertilization of arable land on peat with animal manure or inorganic N-fertilizer.

A sensitivity analysis shows that including the supply of manure to arable land on peat does not lead to a higher weighted average emission factor.

---

Only with an emission factor that is a factor 6 to 8 higher for supply of animal manure to arable land on peat the weighted average emission factor becomes 0.1% point higher. For inorganic N-fertilizer this is only the case when the emission factor is a factor 40 higher.

Experiments on grassland show that the emission factor for peat soils is often a factor 3 to 5 higher than the emission factor for mineral soils. Assuming this increase also applies to arable land it is assumed that the weighted average emission factor is correct.

### *A11.2.2 Variation in N supply to soil*

The share of the N supply to arable land coming from animal manure is for the whole period of 1990 until now on average circa 48%, this share varies between 36 and 57%.

Deviation of the average is therefore at maximum around 25%. For grassland the average N supply from animal manure is circa 52%, this varies between 43 and 64%. Deviation of the average is therefore at maximum around 20%. For grassland on peat soils an average N supply of circa 11% (9-14%) applies.

The share of the N supply to arable land coming from inorganic N-fertilizer is for 1990 until now on average 27%, in which this share varies between circa 23 to circa 41%. Deviation of the average is therefore at maximum around 50%. For grassland the average N supply coming from inorganic N-fertilizer is circa 73%, in which this share varies between circa 59 to 77%. Deviation from the average is therefore at maximum around 20%.

The variation in the shares of the N supply to arable land versus grassland therefore is tens of per cents. Also for the emission factors derived for the various sources the uncertainty is tens of per cents (see standard deviations in Velthof and Mosquera, 2011b).

The uncertainties in the emission factors and in the yearly N supply to mineral versus organic soils with grassland and arable land do not make it necessary to conduct yearly calculation for the distinguished sources. Also for the supply of N<sub>2</sub>O emission figures in international reports disaggregated emission factors are not necessary. From 2011 on the disaggregated data on N supply possibly will not become available yearly<sup>1</sup>. For these reasons multiannual weighted average emission factors are derived for surface spreading, for low emission manure application, for application of inorganic N-fertilizers and for grazing.

### *A11.2.3 Weighted average emission factors*

#### **Animal manure**

For animal manure the (multiannual weighted average) N<sub>2</sub>O emission factor for surface spreading and low emission manure application is respectively 0.4% and 0.9% of the N supply to soil. That is circa a factor 2 lower than the value applied up to now. This applies to surface spreading (decrease from circa 1 to 0.4% of the N supply) as well as low emission manure application (decrease from circa 2 to 0.9% of the N supply).

There is a significant difference in emission factors for low emission manure application and surface spreading. For low emission manure application the N<sub>2</sub>O-N emission factor is a factor 2 higher than for surface spreading, namely 0.9% versus 0.4% of the N supply (Velthof *et al.*, 2010). The share of N in surface spreading decreases strongly between 1990 and 1995 (from 100 to 5%). This makes it necessary to calculate these sources separately in the yearly emission calculations and thus to differentiate separate emission factors for surface spreading and low emission manure application.

---

<sup>1</sup> This as result of the transition to a new calculation methodology for the yearly national ammonia calculations (Velthof *et al.*, 2009 and Van Bruggen *et al.*, 2011). The previously yearly used MAMBO model for the ammonia calculations will be applied by the ER possibly only for the purpose of regionalization. This will likely be less frequent than yearly, for instance 3 yearly.

---

### **Inorganic N-fertilizer**

For inorganic N-fertilizer the (multiannual weighted average) N<sub>2</sub>O-N emission factor is circa 30% higher than the value applied up until now (from circa 1 to 1.3% of the N supply). Reason is that especially for grassland on peat soils the emission factor based on measurement turns out to be higher than assumed (3% instead of 2%).

Also no longer a lower emission factor for ammonium containing (nitrate free) inorganic N-fertilizer is applied, because the available measurements do not provide sufficient basis for different factors. In the Netherlands very few measurements were done; only 3 comparative experiments with a duration of more than 8 months. In 1 of the 3 experiments there seems to be a lower emission factor for the ammonium containing (nitrate free) inorganic N-fertilizer. In the other 2 experiments there is no difference or the emission factor is even higher. Also literature research into international measurements does not provide a definite answer (Velthof and Mosquera, 2011b).

### **Grazing**

For grazing the (multiannual weighted average) emission factor is circa a factor 2 higher based on measurements (urine/dung data in Appendix 1 of Velthof and Mosquera, 2011b); it increases from circa 1.7 to 3.3% N<sub>2</sub>O-N of the N supply.

### **Other sources**

For the emission factor of the smaller sources crop residues, N fixation, histosols and sewage sludge the 'old' values still apply because no new data is available. For histosols the emission factor is 2%. This is consistent with the average of the new emission factors that apply for grassland on peat soils for inorganic N-fertilizer and low emission manure application (respectively 3 and 1%). For crop residues and nitrogen fixation the emission factor is 1%. This is consistent with the average of the emission factors that apply for arable land on mineral soils for inorganic N-fertilizers and low emission manure application (respectively 1 and 1.3%).

### **Comparison to IPCC defaults**

The new emission factor for low emission manure application of 0.9% is lower than the IPCC 1996 default of 1.25%, but is approximately around the **new IPCC 2006** default of 1%. For surface spreading the emission factor is a factor 2 lower than the IPCC 2006 default.

The new emission factor for inorganic N-fertilizer is somewhat higher than the IPCC 1996 default (1.3 versus 1.25%). In comparison to the **new IPCC 2006 default** of 1% of the N supply the country specific value is circa 30% higher.

The new emission factor for grazing is 3.3% of the N supply and with that circa 65% higher than the IPCC 1996 and IPCC 2006 defaults of 2%.

| avg 1990-2008    |                            |                         | 3.2  |

\* N to soil after subtraction of NH<sub>3</sub>-N during application because data without subtraction of NH<sub>3</sub>-N for N to peat respectively mineral soils are not available; in the emission calculations the weighted average emission factors however are related to the total gross N supply to soil (without subtraction of NH<sub>3</sub>-N during application). Assumption is that the differences in evaporation of NH<sub>3</sub> in arable land and grassland are so small that these will not influence the division of the gross N supply over grassland and arable land.

1980-1997: MestAmm data LEI

1997-2005: MAM data LEI

2006-2008: MAMBO data LEI

\*\* In calculation of the shares N to arable land and grassland the N supply to arable land on peat is neglected. The share is relatively small (< 0.2%) and for this source no emission factors are available.

\*\*\* The data 2006-2008 show a break in the trend with the data 1980-2005. Especially there is a factor 8 to 15 increase in the supply of respectively inorganic N-fertilizer and animal manure to arable land on peat. Also there is almost a halving in the supply of N in manure (through fertilization and grazing) to grassland on peat. This correlates to specific data becoming available on the cultivation of crops on several soil types through the Agricultural Census from 2006 on.

---

In the assumption that the supply of manure to arable land is negligible, use of the whole data series (1990-2008) leads to a weighted average emission factor that is circa 0.1% point lower than in use of the data series 1990-2005. For the emission calculation the weighted average emission factor based on the data series 1990-2005 is used to prevent underestimation of the emissions. From a sensitivity analysis follows that there is a reasonable chance that weighing in the supply of manure to arable land on peat does not lead to an even higher weighted average emission factor.

---

# Annex 12 Uncertainty, quality assurance and verification

## A12.1 Estimating uncertainties

For the PRTR dataset of 2013 uncertainties are calculated with the propagation of error method based on literature and expert judgements. Since calculation methods of activity data and emission factors do not change often, this dataset of uncertainties can be used for multiple years. When a calculation method is changed also the uncertainty of the considered activity data or emission factor is adjusted based on literature and expert judgements, to keep the data set of uncertainties up to date.

For each emission source reported in the National Inventory Report (NIR) and the Informative Inventory Report (IIR) an uncertainty is stated. The total uncertainty concerns the square root of the sum of squared uncertainties of the activity data ( $AD_{unc}$ ) and the emission factor ( $EF_{unc}$ ), see formula A12.1. The extent of the total uncertainty is primarily determined by the largest uncertainty.

$$\text{Uncertainty estimate}_{total} = \sqrt{(AD_{unc}^2 + EF_{unc}^2)} \quad (\text{A12.1})$$

When a Tier 1 method is applied to calculate emissions also the default uncertainty is used from the IPCC 2006 Guidelines or EMEP 2009 Guidebook. When a range of uncertainties is being given, the highest uncertainty is used to prevent underestimation. When Tier 2 and Tier 3 methods are used the uncertainties are preferably calculated with use of literature and expert judgements. However, when there is not sufficient information available on the uncertainty of an emission source, the default uncertainty from the IPCC Guidelines or EMEP Guidebook is used.

## A12.2 Quality assurance and quality control (QA/QC)

The PRTR task force leader on Agriculture is responsible for:

1. well documented and adopted data;
2. calculations having been implemented correctly;
3. assumptions are consistent, specific parameters (e.g. activity data) are used consistently;
4. complete and consistent data sets have been supplied.

A yearly check on the above mentioned responsibilities is performed. Any actions that result from these checks are noted on an 'action list' by the ER secretary. The task force leader is responsible for improvements and communicates by e-mail regarding these QC checks, actions and results with the ER secretary.

While adding a new emission year the task force leader performs a trend analysis, in which data from the new year are compared with data from the previous years. The task force leader provides an explanation if the increase or decrease of emissions exceeds the minimum level of 5% at target group level or 0.5% at national level. These explanations are also sent by e-mail to the ER secretary by the task force leader.

The ER secretary keeps a logbook of all these QC checks and trend explanations and archives all concerned e-mails on the ER network. This shows explicitly that the required checks and corrections have been carried out. Based on the results of the trend analysis and the feedback on the control and correction process ('action list') the Working Group on Emissions Monitoring (WEM) gives advice to the institute representatives (Deltares on behalf of Rijkswaterstaat, Statistics Netherlands (CBS) and Netherlands Environmental Assessment Agency (PBL)) to approve the dataset. The ER project leader

---

at RIVM defines the dataset, on receipt of an e-mail by the institute representatives, in which they give their approval.

Furthermore, all changes of emissions in the whole time series as a result of recalculations are documented in CRF table 8(b).

## A12.3 Verification

To check the quality of the calculated emissions for the sources named in this report, general QA/QC-procedures have been followed that are in line with the IPCC Guidelines. These are described further in the QA/QC-programme used by the National System, and the annual working plans published by the PRTR.

### **Sector specific QC**

No additional specific verification procedures are implemented for the sources defined in this sector.

**Published documents in the Technical reports series of the Statutory Research Tasks Unit for Nature & the Environment.**

WOT-technical reports are available from the secretary's office, T 0317 – 48 54 71; E info.wnm@wur.nl  
 Reports can also be downloaded from [www.wageningenUR.nl/wotnatuurenmilieu](http://www.wageningenUR.nl/wotnatuurenmilieu)

The mission of WOT Natuur & Milieu is to carry out statutory research tasks on issues relating to nature and the environment. These tasks are implemented in order to support the Dutch Minister of Economic Affairs, who is responsible for these issues. The Statutory Research Tasks Unit for Nature and the Environment (WOT Natuur & Milieu) works on products of the Netherlands Environmental Assessment Agency (PBL), such as the Assessment of the Human Environment reports and the Nature Outlook reports. In addition, the unit advises the Ministry of Economic Affairs about fertilisers and pesticides and their authorisation, and provides data required to compile biodiversity reports to the European Union.

WOT Natuur & Milieu is part of the international expertise organisation Wageningen UR (University & Research centre). Its mission is 'To explore the potential of nature to improve the quality of life'. Within Wageningen UR, nine specialised research institutes of the DLO Foundation have joined forces with Wageningen University to help answer the most important questions in the domain of healthy food and living environment. With approximately 30 locations, 6,000 members of staff and 9,000 students, Wageningen UR is one of the leading organisations in its domain worldwide. The integral approach to problems and the cooperation between the various disciplines are at the heart of the unique Wageningen Approach.
