COMPARATIVE ANALYSIS OF LEADING AND LAGGING RURAL REGIONS
IN OECD COUNTRIES IN THE 1980S AND 1990S

ABSTRACT

In this paper leading and lagging regions in OECD countries in the 1990s are identified, and a comparative analysis is made of leading and lagging regions in the 1990s with those in the 1980s. The labels 'leading' and 'lagging' are derived from total employment growth. In almost all studied countries, employment growth in the leading predominantly rural and intermediate rural regions in the 1990s tended to exceed that in predominantly urban regions. On the whole, it appeared that about 60% of all leading regions in the 1980s were still leading in the 1990s, and that also 60% of the lagging regions in the 1980s were lagging in the 1990s.

1 INTRODUCTION

‘In which regions does employment grow more than in other regions and what are the reasons behind such differentials in economic performance?’ are intriguing questions, often posed in economic literature. In the 1990s, rural economists applied these questions to rural regions in OECD countries (OECD, 1996; Bollman and Bryden, 1997; EC, 1997; Terluin and Post, 2000; Bryden and Hart, 2001). These studies suggested that the picture of employment growth in rural regions looks like a mosaic of winners, in-betweens and losers, and that quite a number of rural regions outperformed employment growth in urban regions. The existence of dynamic rural regions showed some evidence that the association of rural as being the scene of job and population losses, needs re-adjustment. Most of these studies analysed regional differences in employment growth during a period of about ten years, often in the 1980s. It may be wondered whether rural regions manage to sustain a high employment growth for a longer period. An affirmative answer to this question would imply that forces affecting employment growth positively can be more or less continuously at work over a longer time.

Factors associated with differentials in employment growth in rural regions refer both to tangible and less tangible factors (Bryden and Hart, 2001; Terluin, 2003). Tangible factors correspond to items emphasized in classical production functions like natural resources (land), human resources (labour), investment (capital), infrastructure (technology) and economic structure. Less tangible factors are used to denote an interactive set of attributes of local actors, like capacity, internal and external networks, entrepreneurship, work ethics, regional identity, migration and institutions. Following the mixed exogenous/endogenous rural development approach, which takes account of the increasing globalization process, rural development can be considered as a complex mesh of networks in which resources are mobilized and in which the control of the process consists of an interplay between local and external forces (Lowe *et al.*, 1995). The current globalization process comprises economic, social, political and environmental changes like the increasing mobility of capital; delinking of the different stages of production, which has consequences for the organization of firms; shrinking distances as a result of developments in the communications technology sector; geopolitical changes such as the end of the Cold War; and trade liberalization negotiations. The interplay between local and external forces in rural development suggests that if there are interruptions in economic performance in rural regions over a longer period, this might be due to changes in local forces and/or external forces.

For exploring whether rural regions in the OECD were able to maintain employment growth during the last two decades of the twentieth century, we focus on the following two objectives:

1. Identification of leading and lagging regions in the OECD countries in the 1990s;
2. Comparative analysis of leading and lagging regions in the 1990s with leading and lagging regions in the 1980s.

Although the emphasize in this study is on rural regions, we analyse employment growth in urban regions as well. The economic performance in urban regions serves as a yardstick to assess economic dynamics in rural regions. We restrict this study to a

statistical analysis and disregard from an in-depth analysis of possible changes in local and external forces in rural regions.

The organization of this study is as follows. In Section 2 we discuss the methodological approach of this study. In Section 3 we focus on leading and lagging regions in the 1990s. In Section 4 we conduct a comparative analysis of leading and lagging regions in the 1990s with leading and lagging regions in the 1980s. In the final section we make some concluding remarks.

2 METHODOLOGICAL APPROACH

In this study we use the regional typology of the OECD which is based on population density at local and regional level (see Annex 1 for methodology) and distinguishes three groups of regions (OECD, 1994):

- 1 predominantly rural regions;
- 2 significantly rural (or intermediate rural) regions;
- 3 predominantly urban regions.

Leading, middle and lagging regions

Regional employment growth can be compared with several benchmarks, like the OECD average, national average and the average of the group of rural or urban regions. In this study we look at employment performance in a region relative to employment growth in the other regions of the country in the periods 1980-1990 and 1990-2000. By relating the regional growth rate to the other regions of the country, regional growth rates are corrected for differences among the absolute level of national growth rates. This correction makes sense as the national average employment growth widely varies among OECD countries. Due to our correction we try to explain that part of regional growth which is assumed not to be affected by macro-economic factors but brought about by regional factors. This procedure was also applied in previous international comparisons of regional employment growth (OECD, 1996; Esposti *et al.*, 1999).

In order to examine differences in employment growth among regions, a distinction of regions into groups with, for example, high, medium and low growth is a useful tool of analysis. In this study we use such a ranking of regions within each country as follows: the top-33% is called 'leading', the bottom-33% is labeled as 'lagging' whereas the group in-between is referred to as 'middle'. This grouping contrasts somewhat to previous studies. The OECD (1996) distinguished two groups of regions: dynamic regions with employment growth above the national average and lagging regions in which employment growth was below the national average. In the RUREMPLO project (Esposti *et al.*, 1999) three groups of regions were used: leading, average and lagging. However, the criteria for these groups differ from ours to some extent¹. In all cases, it should be reminded that thresholds are rather subjective. Moreover, it has to be emphasized that here the labels leading and lagging are only derived from employment performance, and that leading regions may be less successful with regard to other indicators like GDP per capita, GDP growth and unemployment rates.

Shift share analysis

Employment growth depends to some extent on the sectoral composition of employment. As agricultural employment tends to decrease, this has a downwards effect on total employment growth. Usually, the share of agriculture in rural regions exceeds that in urban regions. As a positive relation may be assumed between the size of the share of agriculture in total employment and the extent of its downwards effect on total employment growth, this implies that rural regions are in a disadvantageous

¹ In the RUREMPLO project, a region is considered to be 'leading' if the growth rate of non-agricultural employment was 0.5 percentage points above the national growth rate; a region is considered to be 'lagging' if the growth rate of non-agricultural employment was 0.25 percentage points below the national growth rate; the other regions are classified as 'average'.

position relative to urban regions. The same situation applies for regions with declining industrial sectors. By using shift share analysis, the impact of an unfavourable sectoral structure on employment growth can be revealed. Shift share analysis decomposes total employment growth into three components:

1. the national effect: employment growth in the region if it should increase/decrease at the same rate as the national average;
2. the structural effect: employment growth in the region if its industrial sectors should grow at the same rate as the national growth rate of these sectors;
3. territorial dynamics: a residual factor in regional employment growth, which cannot be explained by the national and the structural effect.

Data on employment at the place of work

The base for our analysis of employment growth is data on employment at the place of work, as these reflect the origin of creation of employment. However, due to lack of data or inconsistencies in the time series on employment at the place of work, we had to switch to data on employment at the place of residence in quite a number of cases (see Annex 2 for an overview of data used per country).

3 LEADING AND LAGGING REGIONS IN THE 1990S

In this section, we examine differences in employment growth between predominantly rural, intermediate rural and predominantly urban regions in the 1990s. Due to lack of data, we restrict our analysis to 14 OECD countries.

Table 3.1 Total employment growth in groups of regions in selected countries, 1990-2000 (% p.a.)

Employment growth in leading rural regions often higher than in urban regions

In half of the studied countries, employment growth in the 1990s in the predominantly urban regions exceeded that in the groups of predominantly rural and intermediate rural regions (Table 3.1). In the remaining countries, either predominantly rural or intermediate rural regions showed a higher employment growth than the predominantly urban regions. When we look at employment growth rates in the leading predominantly rural and intermediate rural regions, then it appears that these are above those of the predominantly urban regions in most countries (Fig. 3.1). Only in the Scandinavian countries Norway and Sweden, employment growth rates in the leading predominantly rural and intermediate rural regions lagged behind those in the predominantly urban regions, whereas in Greece, Hungary and Spain either employment growth rates in leading predominantly rural or in leading intermediate rural regions exceeded those in urban regions.

Figure 3.1 Total employment growth in leading pr, leading intermediate rural and predominantly urban regions in selected countries, 1990-2000 (% p.a.)

Source: Own calculations based on OECD Territorial Database.

Leading rural regions characterized by high territorial dynamics

Shift share analysis of employment growth in the predominantly rural regions shows that they usually suffer from a negative structural effect (Table A3.1), which is likely to be caused by a relatively large agricultural sector, but the presence of obsolete industrial sectors may also play a role in this negative structural effect. However, in the leading predominantly rural regions, this negative structural effect is compensated by a positive value for territorial dynamics. This may be due to, for example, a high capacity of the local actors and strong networks in the region. On the other hand, the

lagging predominantly rural regions tend to have negative values for territorial dynamics, reflecting factors like lack of capacity of the local actors and weak networks. Compared to the predominantly rural regions, employment growth in intermediate rural regions is less affected by negative structural effects (Table A3.2). Probably, this may be related to the smaller share of agriculture in total employment in intermediate rural regions. With regard to territorial dynamics, leading and lagging intermediate rural regions show the same pattern as the predominantly rural regions. Finally, predominantly urban regions tend to have a positive structural effect (Table A3.3).

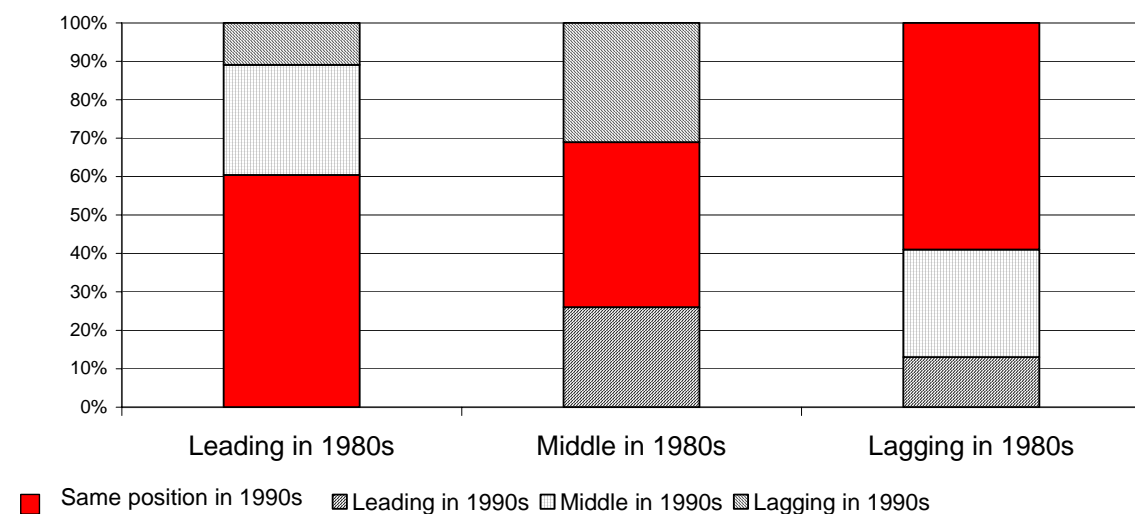

4 COMPARATIVE ANALYSIS OF LEADING AND LAGGING REGIONS IN THE 1990S WITH LEADING AND LAGGING REGIONS IN THE 1980S

In this section we analyse whether regions maintain a relatively high or low rate of employment growth over a longer period, i.e. the 1980s and 1990s. For this purpose, we firstly ranked regions in each country according to their employment growth in the 1980s in a top 1/3 group, a middle 1/3 group and a bottom 1/3 group. Then, we compared the position of regions in the 1980s with that in the 1990s. Due to lack of data, we restrict this comparison to 8 OECD countries.

High or low employment growth not always permanent

On the whole, it appeared that about 60% of all leading regions in the 1980s were still leading in the 1990s, and that also 60% of the lagging regions in the 1980s were lagging in the 1990s (Fig. 4.1). Regions in the middle 1/3 group are even less stable: about 55% experienced a shift to another position. This implies that quite a number of regions were involved in a shift in their relative position, be it in a positive or negative direction.

a) Belgium, Canada, France, Hungary, Japan, Netherlands, Sweden and United States.
Source: Own calculations based on OECD Territorial Database.

Dynamics in predominantly rural regions in the 1980s and 1990s

In the studied countries about 60% of the predominantly rural regions, which were leading in the 1980s, managed to maintain their leading position in the 1990s (Fig. 4.2; Table A4.1)). Most of the other leading predominantly rural regions in the 1980s became middle regions in the 1990s, while about 10% turned into lagging regions. From the predominantly rural regions, which were in the middle group in the 1980s, about 40% stayed in that group in the 1990s. From the shifting middle regions, in

most countries more regions turned into lagging relative to the ones which became leading regions in the 1990s (Fig. A4.1-8). Finally, about 60% of the lagging predominantly rural regions in the 1980s were also lagging in the 1990s, about 30% shifted to the middle group in the 1990s and about 10% became leading in the 1990s.

a) Belgium, Canada, France, Hungary, Japan, Netherlands, Sweden and United States.
Source: Own calculations based on OECD Territorial Database.

Dynamics in intermediate rural regions in the 1980s and 1990s

Compared to the predominantly rural regions, intermediate regions tend to stay more often in the same position in the 1980s and 1990s: more than 70% of the leading intermediate rural regions in the 1980s were also leading in the 1990s, over half of the middle intermediate rural regions in the 1980s had the same position in the 1990s and almost two thirds of the lagging intermediate rural regions in the 1980s were lagging in the 1990s as well (Fig. A4.1-8). Moreover, shifts from a leading position in the 1980s to a lagging one in the 1990s or vice versa hardly occur.

Dynamics in predominantly urban regions in the 1980s and 1990s

The pattern of shifts in the relative position of predominantly urban regions in the 1980s and 1990s rather varies among countries (Fig. A4.1-8): in countries like Canada, Japan and Sweden leading predominantly urban regions in the 1980s tend to stay leading in the 1990s, whereas in other countries like Belgium, France and the US, many leading predominantly urban regions in the 1980s lose their leading position in the 1990s. Apart from a few regions, lagging predominantly urban regions in the 1980s do not manage to become leading in the 1990s.

Convergence and divergence in regional employment growth in the 1980s and 1990s

In order to analyse whether employment growth rates in leading and lagging predominantly rural and intermediate rural tend to converge or diverge in the course

of time, we present the deviation of employment growth in leading and lagging regions from the national average in the 1980s and 1990s (Fig. 4.3). In Belgium and France, deviations of employment growth rates in leading and lagging regions from the national average in the 1990s are smaller than those in the 1980s, so in these countries employment growth rates seem to converge. The same applies for the deviations of employment growth rates in leading and lagging intermediate rural regions in Canada, Japan and the US. However, the deviation of employment growth rates in leading and lagging predominantly rural regions from the national average in these countries tend to be larger in the 1990s relative to the 1980s for either the leading or lagging regions. In Sweden and the Netherlands, the deviation of employment growth rates in both leading and lagging predominantly rural and intermediate rural regions from the national average tends to be larger in the 1990s than in the 1980s, so in these countries divergence in employment growth can be perceived. Finally, in Hungary no clear pattern in the deviation of employment growth in leading and lagging regions in the 1980s and 1990s from the national average can be found, which is likely to be due to the economic transition period this country experienced in the 1990s.

Figure 4.3 Deviation of employment growth in leading and lagging predominantly rural and intermediate rural regions from the national average in the 1980s and 1990s (in % points)

5 CONCLUDING REMARKS

In this paper we identified leading and lagging predominantly rural and intermediate rural regions in OECD countries in the 1990s, and we explored whether these regions had a similar position in the 1980s. The labels 'leading' and 'lagging' were derived from total employment growth.

In almost all studied countries, employment growth in the leading predominantly rural and intermediate rural regions in the 1990s tended to exceed that in predominantly urban regions. This pattern has also been perceived in the 1980s (OECD, 1996; Terluin, 2003).

Shift share analysis in the leading predominantly rural and intermediate rural regions revealed that employment growth in the 1990s was usually composed of a negative value for the structural effect – due to a relatively large agricultural sector and/or the presence of obsolete industrial sectors – and a positive value for territorial dynamics. This suggests that employment growth in the leading predominantly rural and intermediate rural regions depends to a high degree on specific local and regional factors, like capacity of the local actors, entrepreneurship, networks and participation. On the other hand, employment growth in the lagging predominantly rural and intermediate rural regions tend to be composed of both a negative value for the structural effect and territorial dynamics. This shows that lagging predominantly rural and intermediate rural regions are likely to suffer from both obsolete industrial sectors, lack of capacity of local actors and weak networks.

From the analysis of the leading or lagging position of regions in the 1980s and 1990s, it appears that about 60% of the leading predominantly rural regions in the 1980s were also leading in the 1990s. From the remaining leading predominantly rural regions in the 1980s, 30% shifted to the middle group in the 1990s and 10% became lagging in the 1990s. The lagging predominantly rural regions in the 1980s seem to follow a more or less similar pattern: 60% were also lagging in the 1990s, 30% shifted to the middle group and 10% to the leading group. Quite a number of leading and lagging intermediate rural regions in the 1980s also shifted to another position in the 1990s, although to a lesser extent than the predominantly rural regions. Moreover, leading and lagging intermediate rural regions in the 1980s hardly changed into lagging or leading in the 1990s. The shifts in the relative position of regions in the 1980s and 1990s give rise to three related comments:

- a. being leading or lagging is not always a permanent situation;
- b. some leading predominantly rural and intermediate rural regions manage to maintain a high rate of employment growth over a longer period;
- c. some lagging predominantly rural and intermediate rural regions do not manage to overcome a situation of employment stagnation over a longer period.

The deviation of employment growth rates of leading and lagging predominantly rural and intermediate rural regions from the national average in the 1980s and 1990s showed a decrease in the course of time in some studied countries and an increase in others. So some countries experience convergence of regional employment growth rates, where other countries face a divergence of regional employment growth rates.

ANNEX 1 TERRITORIAL SCHEME OF THE OECD

In the scope of the Project on Rural Indicators, the OECD has made a typology of rural regions, which covers its whole territory (OECD, 1994). The typology consists of three types of regions, derived on population density:

- 1 predominantly rural regions;
- 2 significantly rural (or: intermediate) regions;
- 3 predominantly urban regions.

The typology is based on a territorial scheme of two hierarchical levels: the local community level and the regional level. Local communities are basic administrative units with a very detailed grid, like cantons in France, districts in the UK and municipalities in the Netherlands. Regions are larger administrative units or functional zones with a less detailed grid, like aemter in Denmark, provincias in Spain and provinces in Belgium and the Netherlands. When population density in local communities is less than 150 inhabitants per square kilometre, the community is classified as 'rural'; when population exceeds 150 inhabitants per square kilometre as 'urban'². As a second step, regions are divided into three groups (Fig. A1):

- when more than 50% of the population of the region lives in rural local communities, the region is classified as 'predominantly rural';
- when between 15 and 50% of the population of the region lives in rural local communities, the region is classified as 'significantly rural' or 'intermediate'³;
- and when less than 15% of the population of the region lives in rural local communities, the region is classified as 'predominantly urban'.

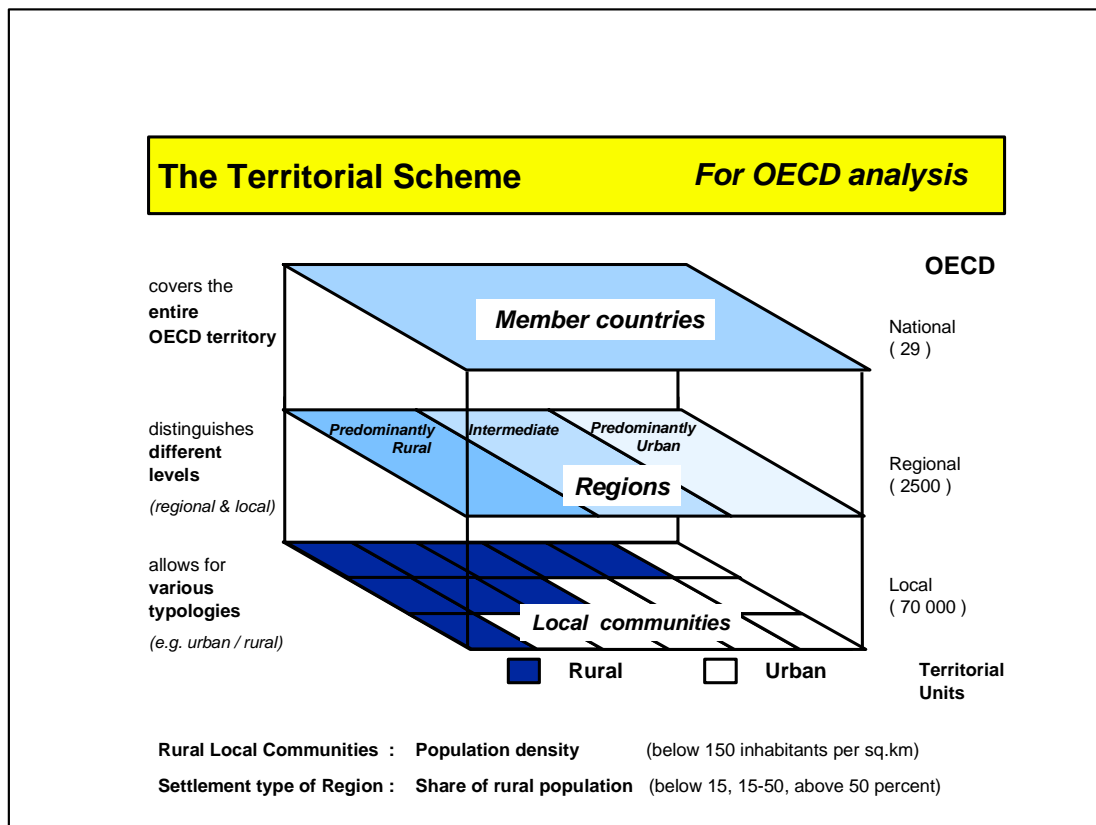

Moreover, when regions include a city of 200,000 inhabitants or more, the region is classified as intermediate; when regions include a city of 500,000 inhabitants or more, the region is classified as predominantly urban.

Within the scope of this scheme, a basic set of socio-economic indicators for these regions has been collected as well. The OECD designed this scheme and database of internationally comparable indicators in order to help member countries to improve their monitoring of changes and trends in rural economies, and to contribute to a sounder basis for decision making in rural development policy.

² For Japan the threshold is 500 inhabitants per square kilometre.

³ Originally, the term 'significantly rural' was used; as this was difficult to interpret for many users, later the term 'intermediate' was introduced.

ANNEX 2 OVERVIEW OF USED DATA

The OECD Territorial Database classifies employment according to the International Industrial Classification System (ISIC) where:

1. 'agricultural employment' refers to:
ISIC = 1, which includes employment in agricultural, forestry and fishing enterprises;
2. 'industry' refers to:
ISIC = 2, which is mining and quarrying;
ISIC = 3, which is manufacturing;
ISIC = 4, which is electricity, gas and water utilities; and
ISIC = 5, which is construction.
3. 'services' refers to:
ISIC = 6, which is wholesale and retail trade and restaurants and hotels;
ISIC = 7, which is transportation, storage and communication;
ISIC = 8, which is finance, insurance, real estate and business services; and
ISIC = 9, which is community, social and personal services.

Belgium

Data by sector by place of residence was obtained from Eurostat for 1983 and 1990 and 2000.

For 1980, the 1983 data by sector were used to distribute the 1980 employment at place of residence across the sectors.

For 1990 and 2000, the distribution of employment by sector is used to prorate the total employment at place of residence across the three sectors.

Thus, in this paper, employment by sector for 1980 and 1990 and 2000 refers to employment at place of residence.

Note that the employment data at the national level for 1980 using employment at place of work was 10 percent lower than for employment at place of residence. The employment data at the national level for 1990 using employment at place of work was 3 percent less than for employment at place of residence. The employment data at the national level for 2000 using employment at place of work was slightly greater (about ½ of 1 percent) than for employment at place of residence. Thus, the calculation of national employment growth between 1980 and 1990 will differ by 7 percentage points, depending upon whether one uses the data for employment at place of work or employment at place of residence.

Canada

Canadian census data for employment by sector were tabulated at place of residence (although they could have been tabulated at place of work). For 1981 and 1991, the sum across sectors was less (by less than 1 percent) than the total employment at place of residence, due to differences in the way the total population was defined in the two separate data requests (one difference is due to a difference in the coverage of individuals in the military). The 2001 data of employment by sector was (unintentionally) tabulated for the 'experienced workforce.' The 'experienced workforce' includes individuals unemployed in the week preceding the census (on May 14) if they had a job since January of the previous year. This gives a better picture of the industrial structure of a region because it picks up the job structure of employment over the previous 15 months – however, compared to the level of employment recorded for

the week preceding the census, some regions will have an experienced labour force that is 20 percent higher than the level of employment for the week preceding the census. {We will re-tabulate the 2001 census data to make this consistent}.

For each of 1981 and 1991 and 2001, the level of employment by sector is prorated to equal the level of employment at place of residence.

Thus, in this paper, non-agricultural employment for 1981 and 1991 and 2001 refers to employment at place of residence and was calculated as total employment minus agricultural employment.

France

Employment data by sector for 1980, 1990 and 1999 is at place of work.

Thus, in this paper, non-agricultural employment for 1980 and 1990 and 1999 refers to employment at place of work and non-agricultural employment was calculated as total employment minus agricultural employment.

The 1980 employment data for place of work at the national level is slightly less (less than 1/2/ of 1 percent) than the employment data for place of residence. In 1990, the national place of work data is 1 percent larger than the national data for place of residence. The 1999 national level place of work employment is 2 percent less than the 2000 national level place of residence data. Thus, the calculation of national employment growth between 1990 and 1999 or 2000 may differ by at least 1 percentage point, depending upon whether one uses the data for employment at place of work or employment at place of residence.

Germany

Employment data by industrial sector is not available for all TL3 regions for 1980. The 1990 and 1999 employment data by sector summed to both the total employment by place of work and the total employment by place of residence.

Thus, in this paper, non-agricultural employment for 1990 and 1999 refers to employment at place of residence (and the data is the same for place of work) and non-agricultural employment was calculated as total employment minus agricultural employment.

Greece

Employment data by sector is not available for 1980. Employment data by sector for 1991 and 2000 is tabulated at place of residence. The sum of employment across sectors in 1991 was 1 percent less than total employment and the distribution of employment by sector was used to pro-rate the total employment across sectors.

In this paper, non-agricultural employment for 1991 and 2000 refers to employment at place of residence and non-agricultural employment was calculated as total employment minus agricultural employment.

Hungary

Employment data by sector is at the place of work for 1980, 1990 and 2000. However, the data show an increase in employment over time because the coverage of the survey increased over time. The trend for national employment at place of residence is to show a decline in national employment over time.

To maintain the correct trend at the national level, the employment at place of residence was prorated across the sectors by the employment by sector (at place of work).

Thus, in this paper, non-agricultural employment for 1990 and 2000 refers to employment at place of residence.

Japan

The sum of employment across sectors equals the employment at place of residence for 1980 and 1990. At the national level, the 2000 sum of employment across sectors is about 1 percent less than the national data for employment at place of residence. The distribution of employment by sector for 2000 was used to prorate the employment by place of residence across the sectors.

Thus, in this paper, non-agricultural employment for 1980 and 1990 and 2000 refers to employment at place of residence and non-agricultural employment was calculated as total employment minus agricultural employment.

Mexico

Employment data by sector was available for 1990 and 2000.

The sum of employment across sectors equals the employment at place of work.

Thus, in this paper, non-agricultural employment for 1990 and 2000 refers to employment at place of work and non-agricultural employment was calculated as total employment minus agricultural employment.

Note that the 2000 national data by place of work is 3 percent less than the national data by place of residence. Thus, the calculation of employment growth in the 1990 to 2000 period will differ by 3 percentage points, depending upon which data series is used.

Netherlands

The 1980 national data for the sum of employment across sectors is equal to the employment at place of residence for each TL3 region except Overijssel, Gelderland and Flevoland). For these three regions, the employment at place of residence was prorated across the sectors using the data on employment by sector (at place of work).

The 1990 national data for the sum of employment across sectors is equivalent to the national data for employment at place of residence.

The 2000 data for the sum of employment across sectors is 6 percent less than the 2000 national data for employment at place of residence.

For 2000, we have used the 2000 distribution of employment across sectors to prorate the employment at place of residence across sectors.

Thus, in this paper, non-agricultural employment for 1980 and 1990 and 2000 refers to employment at place of residence and non-agricultural employment was calculated as total employment minus agricultural employment.

New Zealand

For each of 1981 and 1991 and 2001, the sum of employment across sectors equals the data for employment at place of work. For 1991 and 2001, it is also equal to the employment at place of residence. However, in 1981, the national data for employment by place of work (and also the national data for employment across sectors) is larger by 9 percent, compared to the national data for employment by place of residence. The consequence is that the 1981 to 1991 employment change is negative for the country and certainly for the largest centres if one uses employment by place of residence BUT employment change is positive if one uses the data for employment by place of residence (and again this is most obvious for the larger centres). Consequently,

it is not clear which data series is correct. For the interim, pending clarification, we shall not calculate non-agricultural employment for 1981.

Thus, in this paper, non-agricultural employment in 1991 or 2001 refers to employment at place of residence (which is also the same as employment at place of work) and non-agricultural employment was calculated as total employment minus agricultural employment.

Norway

In 1980, the sum of employment across sectors was equal to the national level for employment at place of work but this was 29 percent less than the national level for employment at place of residence. If we were to choose employment at place of residence as the control total, then we could use the distribution of employment by sector to prorate the employment at place of residence across sectors. However, the discrepancy of 29 percent seems larger – although the discrepancy is close to 29 percent in each of the TL3 regions.

In 1992, the sum of employment across sectors was 5 percent less than the employment at place of residence and 2 percent less than the employment at place of work.

In 2000, the sum of employment across sectors was 1 percent less than the 2000 employment at place of residence and 1 percent less than the 2000 employment at place of work (because employment at place of work and employment at place of residence were equal in 2000).

To estimate non-agricultural employment, we have chosen employment at place of work as the control totals for 1992 and 2000 and used the data on employment by sector to prorate employment across the sectors.

Note that the 1990 place of work data is 4 percent less than the place of residence data but the 2000 place of work data is 1 percent less than the place of work data. Thus, a calculation of employment growth between 1990 and 2000 will differ by 3 percentage points, depending upon which data series one chooses.

Thus, in this paper, non-agricultural employment in 1992 and 2000 refers to employment at place of work and non-agricultural employment was calculated as total employment minus agricultural employment.

Spain

Employment data by sector were not available for 1981.

The 1991 employment data by sector at the national level was 1 percent less than the national place of work data. Consequently, the employment data by sector was used to prorate the place of work data across sectors.

The 2000 employment data by sector did sum to the place of work data.

In this paper, non-agricultural employment for 1991 and 2000 refers to employment at place of work and non-agricultural employment was calculated as total employment minus agricultural employment.

Note that the 1991 national employment place of work data is 5 percent larger than the 1991 national employment place of residence data. The 2000 national place of work data is 7 percent larger than the 2001 place of employment data. Thus, the calculation of the national employment growth will differ by about 2 percentage points, depending upon the data series used for the calculation.

Sweden

The 1990 employment data by sector at the national level was 1 percent less than the national place of work data. Consequently, the employment data by sector was used to prorate the place of work data across sectors.

For 1980 and 1999, the national employment data by sector was equal to the place of work data.

In this paper, non-agricultural employment for 1980 and 1990 and 1999 refers to employment at place of work and non-agricultural employment was calculated as total employment minus agricultural employment.

Note that the national place of work data is greater than the national place of residence data (by 2 percent in 1980 and by 3 percent in 1990 and the 1999 place of work data is greater than the 2000 place of residence data by less than ½ of 1 percent). Consequently, the calculation of national employment growth will differ by 1 to 3 percentage points over this period, depending upon the data series used for this calculation.

US

Employment data by sector were available for 1980 and 1990 and 2000. These data at the national level track the national data on employment at place of residence. Consequently, the employment data by sector was used to prorate the employment data by place of residence across sectors for each of 1980 and 1990 and 2000.

In this paper, non-agricultural employment for 1980 and 1990 and 2000 refers to employment at place of residence and non-agricultural employment was calculated as total employment minus agricultural employment.

ANNEX TABLES

Table A2.1 Overview of leading, middle and lagging regions in the studied countries in the 1980s and 1990s (excluding Canada, Mexico and US)
