Characteristics of biomass

Characteristic	Action
small quantities scattered over many sources locations (regions)	collection & transport
inhomogeneous quality	pre-treatment
relatively high moisture content	drying
different types (crops, residues)	pre-treatment & flexible power plants
seasonal patterns	storage
lower energy content than fossil fuels	pre-treatment

Logistics bio-energy chain

- economic feasibility has to be studied carefully, before one can start to build and operate a power plant
- costs of logistics may determine a major part of feasibility, especially when biomass costs only are relatively low

Complexity logistics

- the logistics are often complex and can be set up in many different ways
- this makes it difficult to estimate the logistical costs and energy consumption and therefore modelling the logistics of a design can be very useful

Logistical questions

- which biomass from what sources?
- where and what type of pre-treatments?
- what is the best location for conversion plant?
- optimal scale of conversion plant?
- what are chain costs (transport, storage, treatment)?
- what is energy consumption in chain?

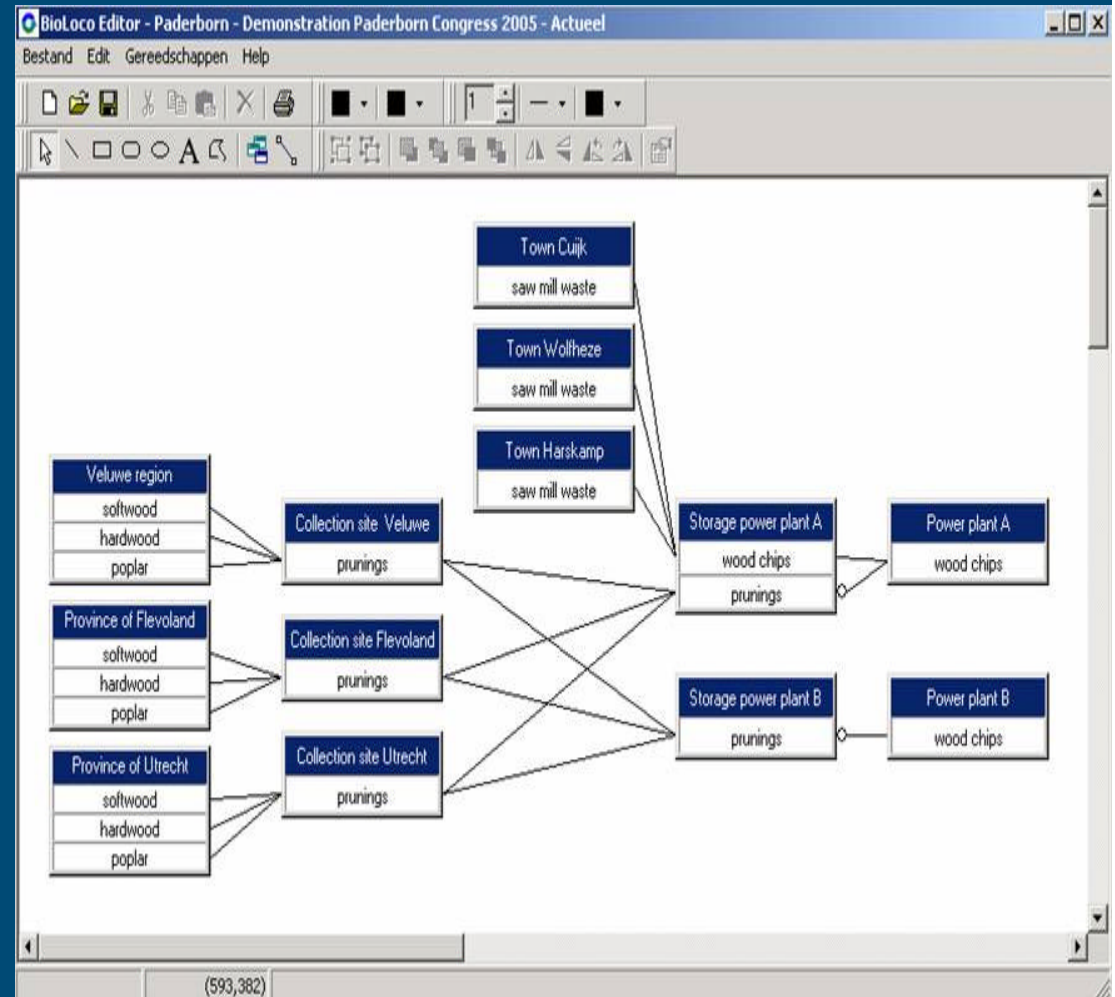

Logistical biomass models

- Biomass logistic computer simulation (Biologics)
 - Animation: Virtual Reality Biologics
- Biomass logistic computer optimisation (Biolooco)
 - Classic
 - Light
 - Emissions

Modelling the logistics of a bio-energy chain

- by means of a network structure
- nodes:
 - source locations
 - collection sites
 - transshipment sites
 - pre-treatment sites
 - conversion site
- arc:
 - transport

Simulation versus optimization

Simulation (Biologics)

The simulation model takes a given, well defined design of the logistical network, and then calculates the effects of the dimensions of this network. Biologics does not make any choices between alternative source locations, transport systems, energy plants, etc. Therefore slightly different designs need new simulation runs with Biologics.

The calculations of the simulation model can be more detailed than the optimisation model calculations. For example Biologics calculates at a day-to-day level

Both models calculate the financial and energetic performance. With Biologics, the user has to decide which performance criterion is preferred.

Optimization (BioloCo)

The optimisation model establishes the optimal design of the logistical network within some broader boundaries e.g. a list of alternative source locations, transport systems, energy plants, etc. BioloCo chooses the best source locations, transport systems, energy plants, etc. It only takes one run of BioloCo to find the optimal network within these specified broader boundaries.

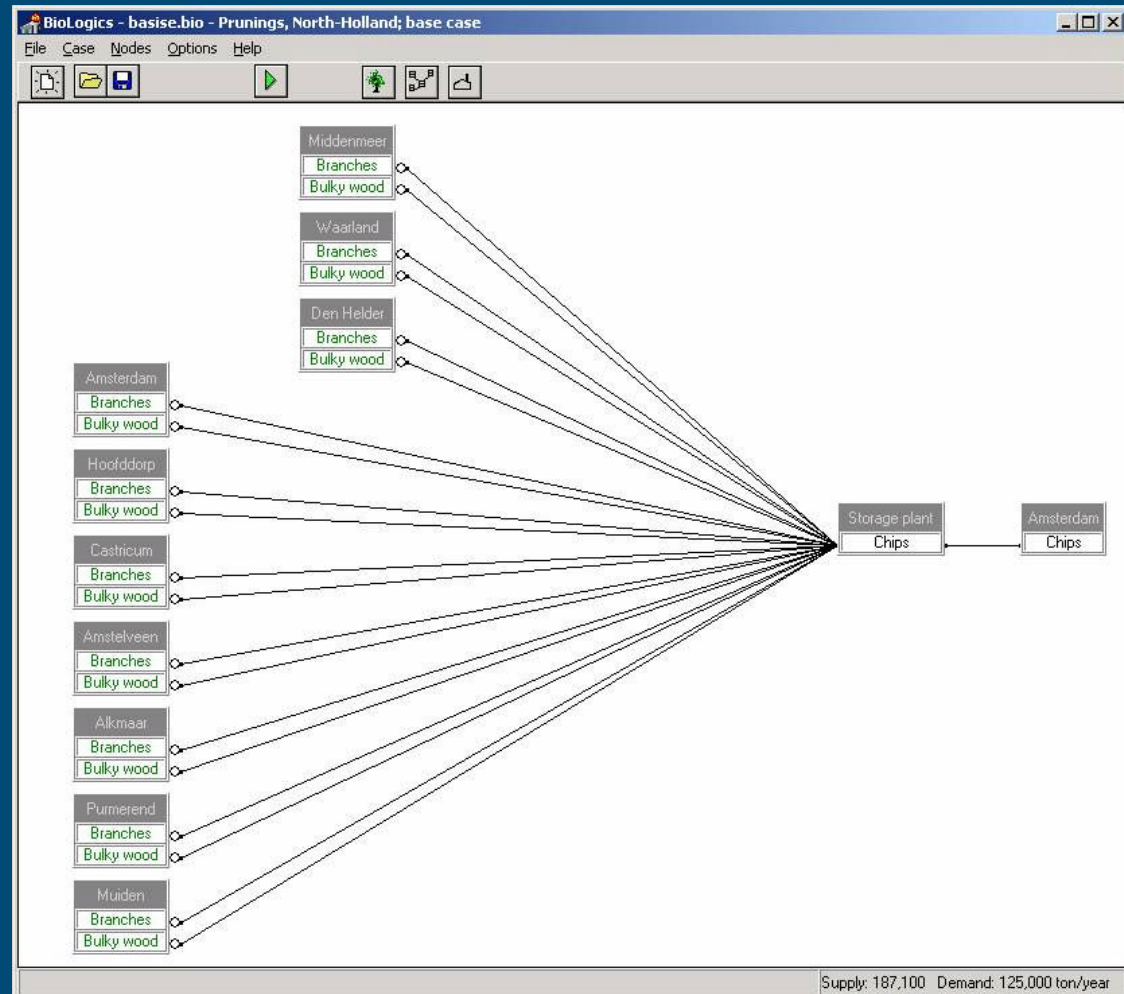

BioloCo has the month as time unit.

The user of BioloCo has to choose an optimisation criterion at forehand.

Biomass logistic computer simulation

- Biologics
- simulation of given scenario

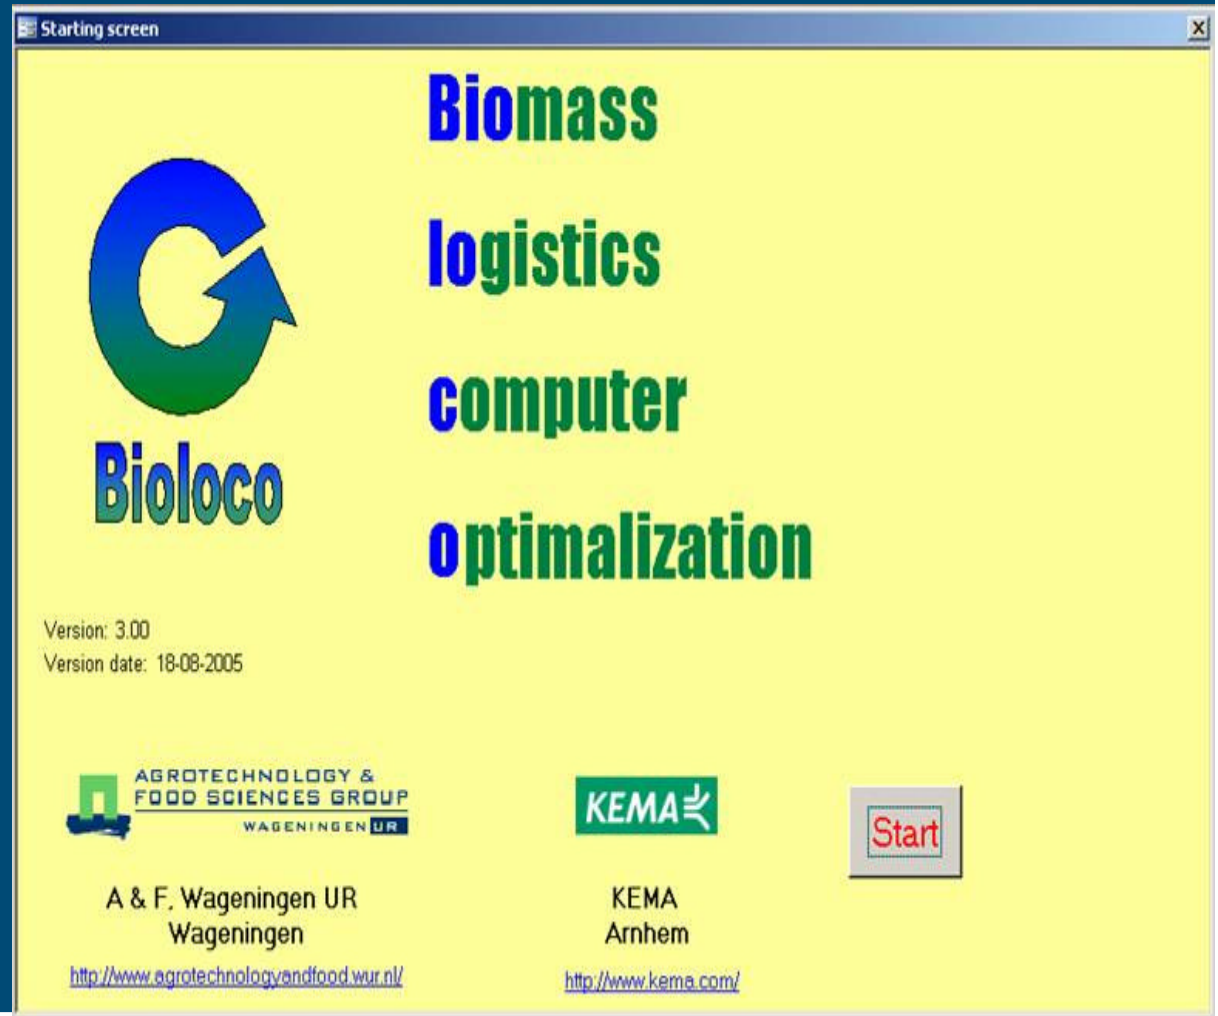

Animation of logistics

- Virtual Reality
- visual analysis

Biomass logistic computer optimization

- Biolooco
- determines an optimal solution under given circumstances

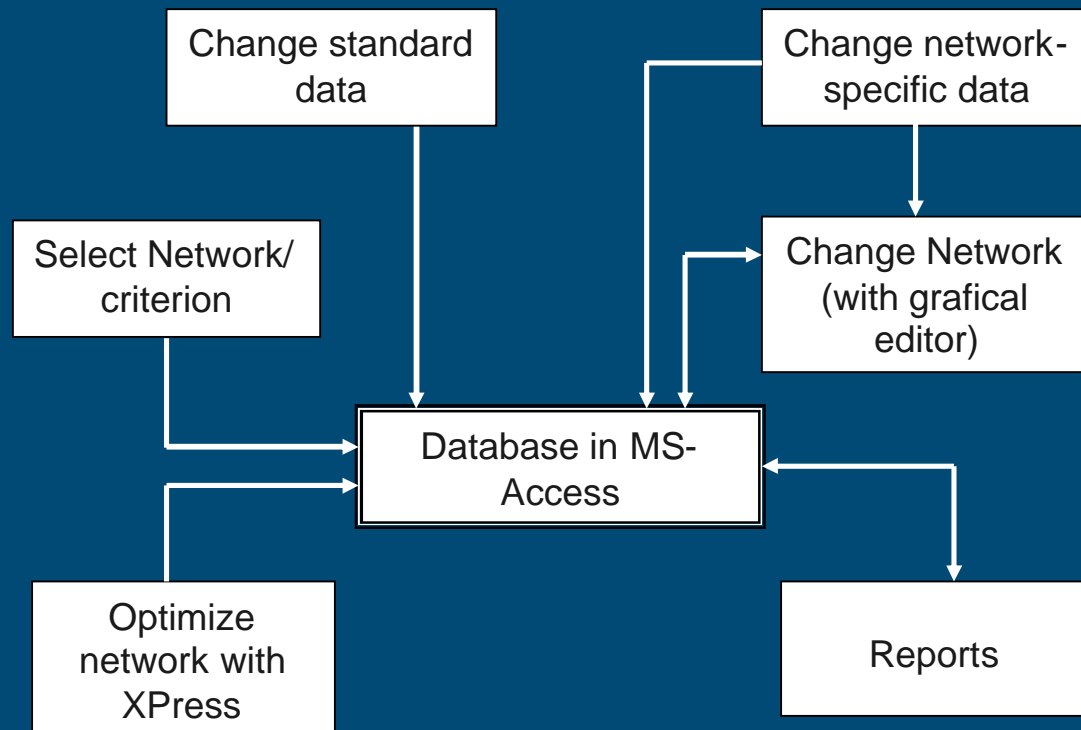

Characteristics of Bioloco

- Bioloco calculates the optimal bio-energy chain (within certain constraints):
 - biomass types
 - transport types
 - storage facilities
 - pre-treatment methods
 - conversion techniques
- based on a chosen optimisation criterion (financial, energetic or emission) or combination (goal programming)

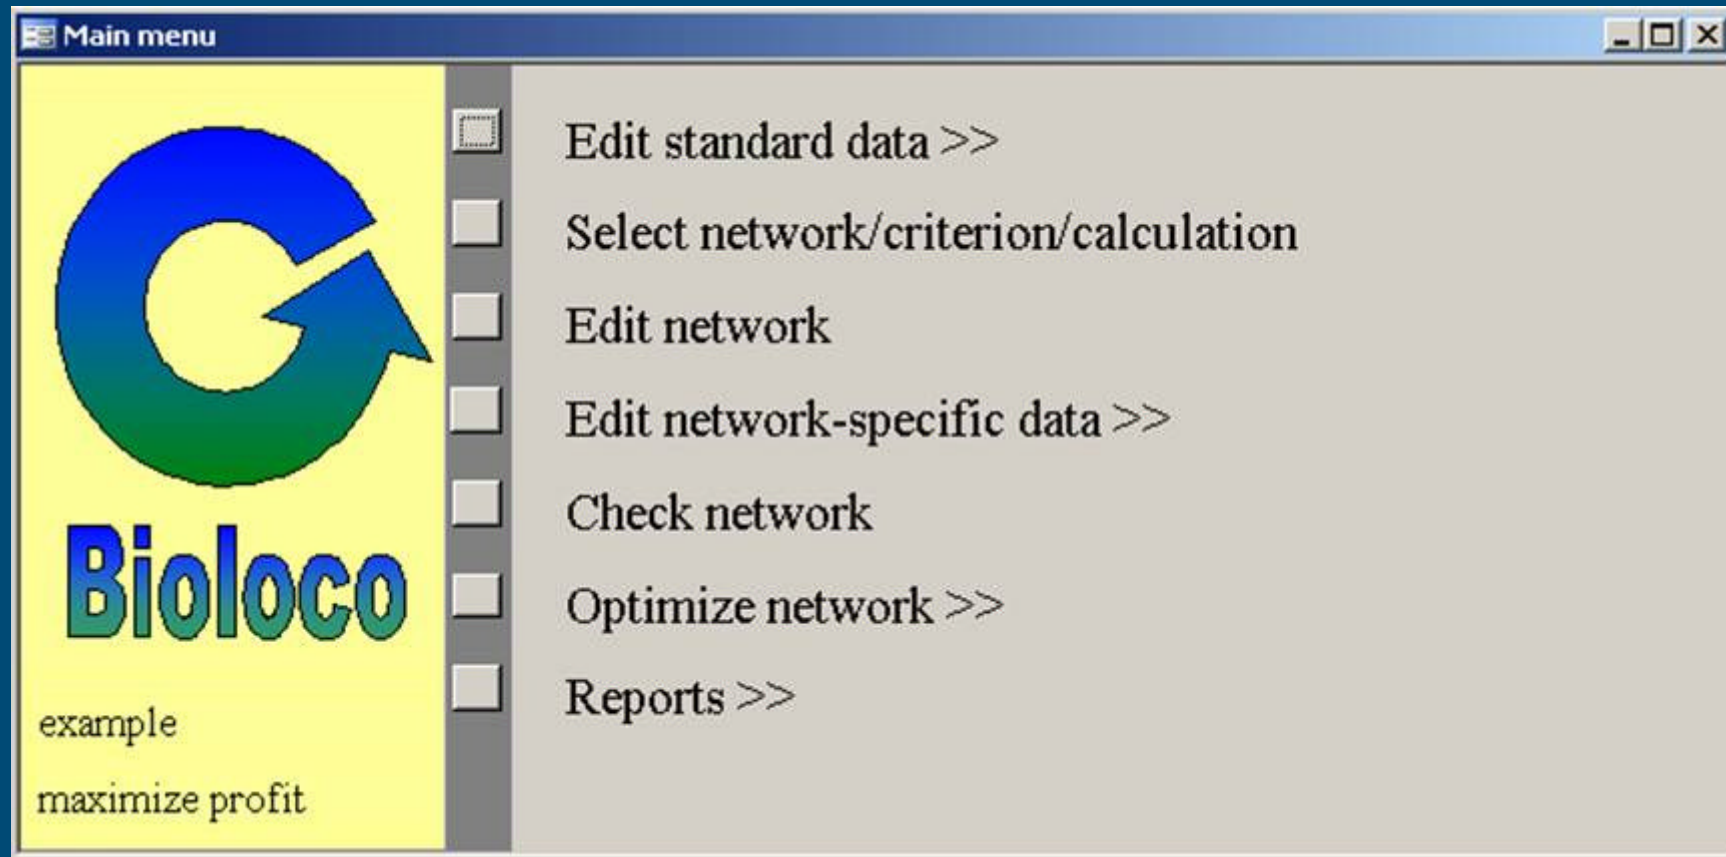

Typical biomass constraints in Biolooco

- During optimisation Biolooco takes into account effects that are typical for biomass:
 - seasonal fluctuations in supply and demand of biomass
 - losses of water due to drying (positive effect)
 - losses of dry matter due to heating (negative effect)

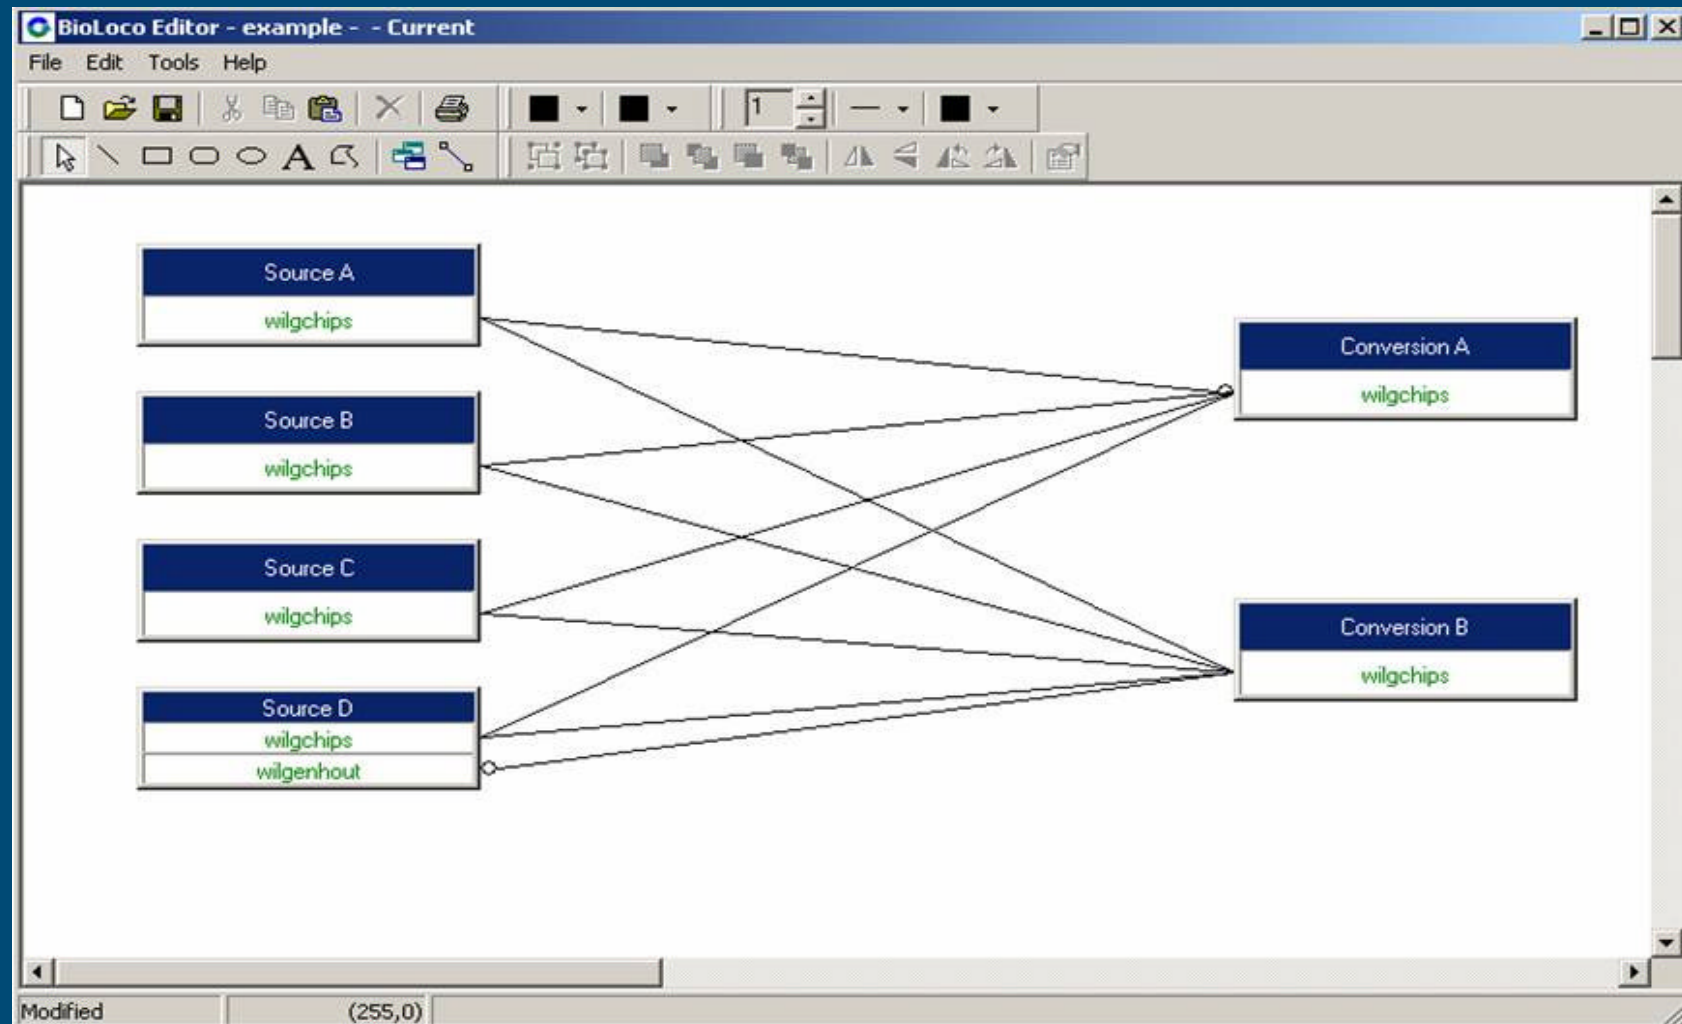

The structure of Bioloco

Bioloco - menu structure

BioloCo – options in a network structure

BioloCo - biomass types

Biomass types

name wilgchips

description chips of willow whole stems

bulk density 150

manifestation chips

heating 0.015

WAGENINGEN UR

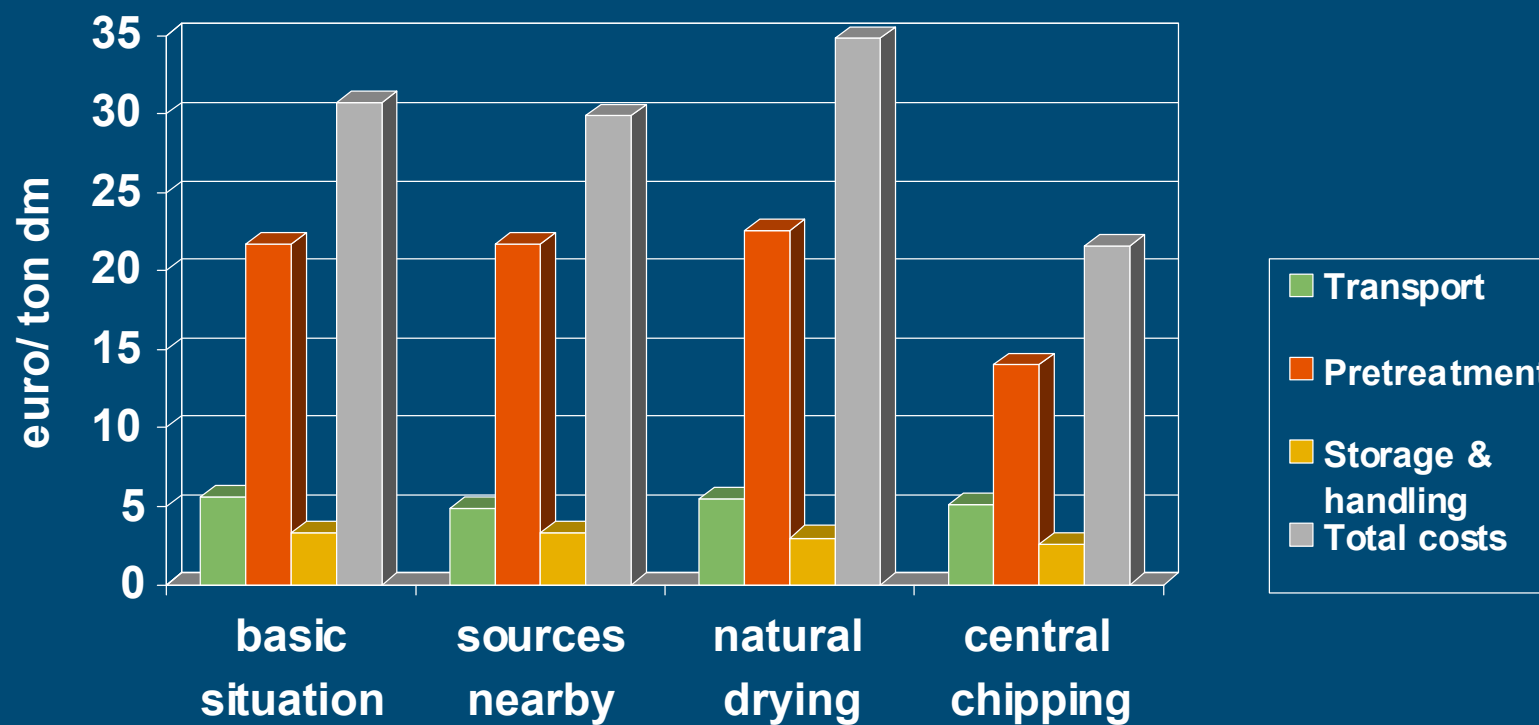

Page 1 of 1

Biolooco used in several regional cases

- provincial plans: biomass power plant in North-Holland
- municipal plans: biomass utilization in Wageningen & multifunctional land use in Hardenberg
- plans of a large petrol company to use straw as an energy source
- environmental effect report
- research plans: biomass cultivation combined with quality improvement of dredging sludge by means of on-site bio remediation

Results: example costs

Results: example energy consumption

Conclusion

- careful strategic design of logistics is important to obtain feasible bio-energy chains
- simulation and optimization tools are available to support this design process
