Wageningen, 2012

Abstract

Krujne, R., A.M.A. van der Linden, J.W. Deneer and J. G. Groenwold and E.L. Wipfler, 2011. *Appendices NMI 3*. Wageningen, Alterra-report 2250.2, 108 pp.; 3 fig.; 56 tab.; 7 maps; 38 ref.

The NMI 3 focusses on indicators for emissions to surface water and the related aquatic risk resulting from agricultural use of pesticides in the Netherlands. The risk indicator is the exposure toxicity ratio. The model also considers the risk to groundwater, soil organisms and the terrestrial ecosystem. The model calculates indicators for emission to surface water resulting from atmospheric deposition, spray drift, drainage flow, point sources, discharge from greenhouses. The model combines a wide range of information about pesticide sales, usage, spray drift mitigation, emission factors, crop maps, surface water, soil, climate, and substance properties. The primary goal is to compare on a relative scale the annual risk at national scale at the starting and end year of the policy period. The results can be used for ranking, for comparing applications of similar type and for visualisation of spatial patterns of indicators. The result cannot be translated into a risk at a specific location and time.

Keywords: risk indicator, environment, sustainable use, pesticides, policy evaluation, NMI.

Appendix 1 Surface water dimensions and maps	7
Appendix 2 Implementation drift reducing measures	17
Appendix 3 Drift factors (standard ditch)	41
Appendix 4 Compounds and drainage group	59
Appendix 5 Crop data	69
Appendix 6 Overview of spray drift treatments and crops	77
Appendix 7 Substance flow in soilless cultivation systems	79
Appendix 8 Review of the scientific panel (in Dutch)	95
Appendix 9 Pesticide environmental risk indicators literature search conducted in 2009	99

Appendix 1 Surface water dimensions and maps

Surface water maps (resolution 250 x 250 m²)

1. Length of large field ditches with pipe drain outlet (m ha⁻¹)
2. Length of medium size field ditches with pipe drain outlet (m ha⁻¹)
3. Length of small field ditches with pipe drain outlet (m ha⁻¹)
4. Total water volume per unit area (1 ha) agricultural land (m³ ha⁻¹)
5. Average water volume in field ditches, per m ditch length (m³ per m)
6. Average width of the water body in field ditches (m)
7. Average ratio width of the water body : water volume per m ditch length (m⁻¹)

The average dimensions shown in maps 5, 6, 7 are calculated from the length, the cross-sectional dimensions and the water depth per ditch class (maps 1, 2, 3).

Field ditch dimensions

Field ditch dimensions are used in emission and exposure calculations. The length L and volume of water V are used in the equations in the main report and expressed per unit of 1 ha agricultural land per ha.

The total length of field ditches per unit area of agricultural land in the plot:

$$L = \sum_{s=1}^3 (L_s) \quad (\text{Eq. 1})$$

L_s length of field ditches per unit area of agricultural land in the plot (m ha⁻¹)
L total length of field ditches per unit area of agricultural land in the plot (m ha⁻¹)
s watercourse class index (1 ≤ s ≤ 3)

The average width of the water body is used for calculating the atmospheric deposition and spray drift deposition, and for calculating the volatilisation rate coefficient:

$$B = \frac{\sum_{s=1}^3 (B_s L_s)}{L} \quad (\text{Eq. 2})$$

B average width of the water body in field ditches in the plot (m)
B_s width of the water body in the field ditch (m)
L_s length of field ditches per unit area of agricultural land in the plot (m ha⁻¹)
L total length of field ditches per unit area of agricultural land in the plot (m ha⁻¹)
s watercourse class index (1 ≤ s ≤ 3)

The water volume is used for calculating the peak concentration in the field ditch:

$$V = \sum_{s=1}^3 (L_s v_s) \quad \text{Eq. (3)}$$

$$v_s = b_s d_s + z_s d_s^2 \quad \text{Eq. (4)}$$

V	total volume of water in field ditches per unit area of agricultural land in the plot ($\text{m}^3 \text{ ha}^{-1}$)
L_s	length of field ditches per unit area of agricultural land in the plot (m ha^{-1})
v_s	volume of water per unit length ($\text{m}^3 \text{ m}^{-1}$)
b_s	bottom width (m)
d_s	water depth (m)
z_s	side slope factor ($h : v$)
s	watercourse class index ($1 \leq s \leq 3$)

The volume of water per unit length is used for calculating the volatilisation rate coefficient:

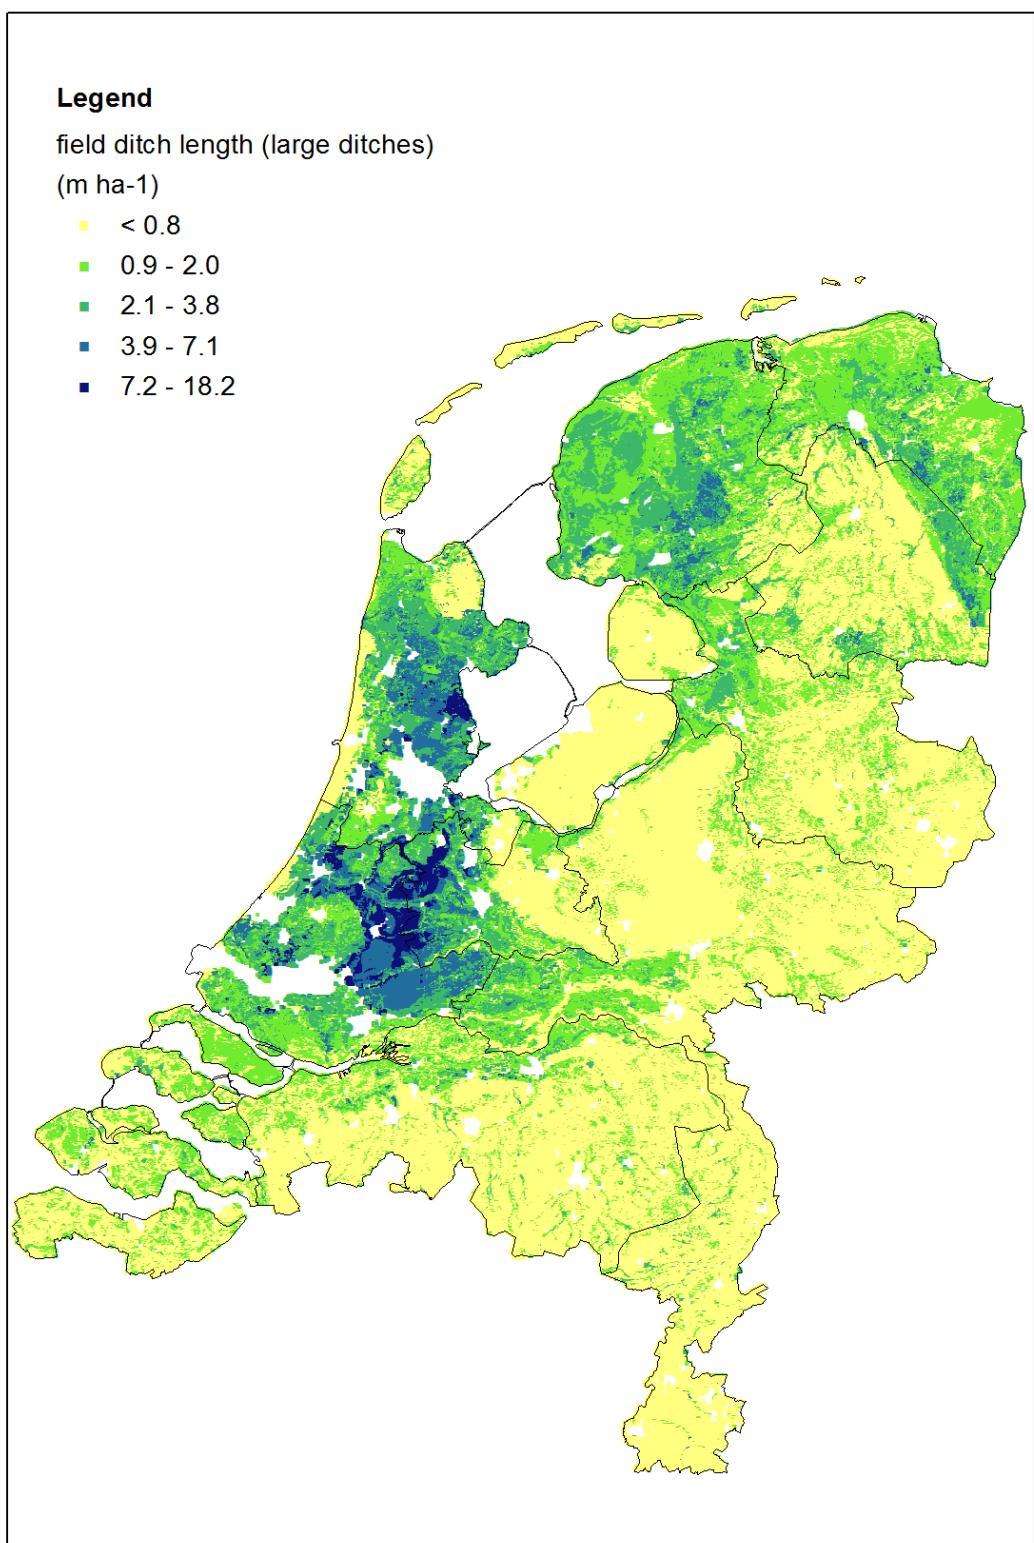

$$v = \frac{V}{L} \quad \text{Eq. (5)}$$

v	water volume per unit field ditch length in the plot ($\text{m}^3 \text{ m}^{-1}$)
V	total volume of water per unit area of agricultural land in field ditches in the plot ($\text{m}^3 \text{ ha}^{-1}$)
L	total length of field ditches per unit area of agricultural land in the plot (m ha^{-1})

Assuming a rectangular cross-sectional profile, the depth of the water body in the field ditches;

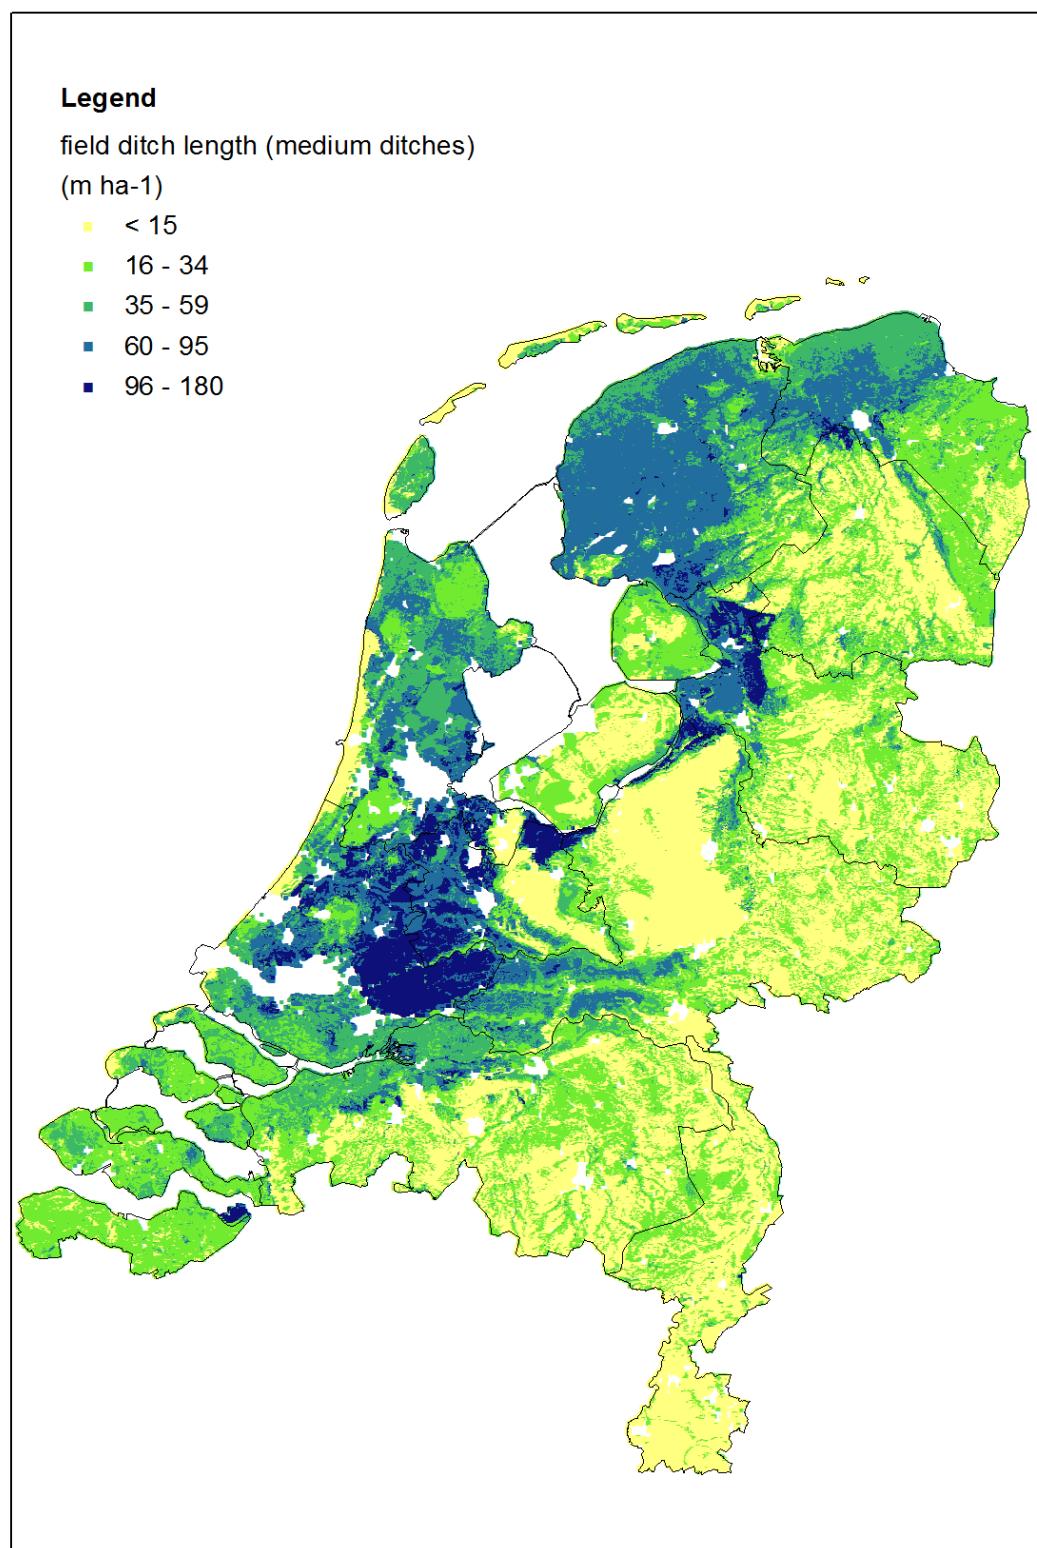

$$d = \frac{v}{B} \quad \text{Eq. (6)}$$

d	water depth in field ditches in the plot (m)
v	water volume per unit field ditch length in the plot ($\text{m}^3 \text{ m}^{-1}$)
B	average width of the water body in field ditches in the plot (m)

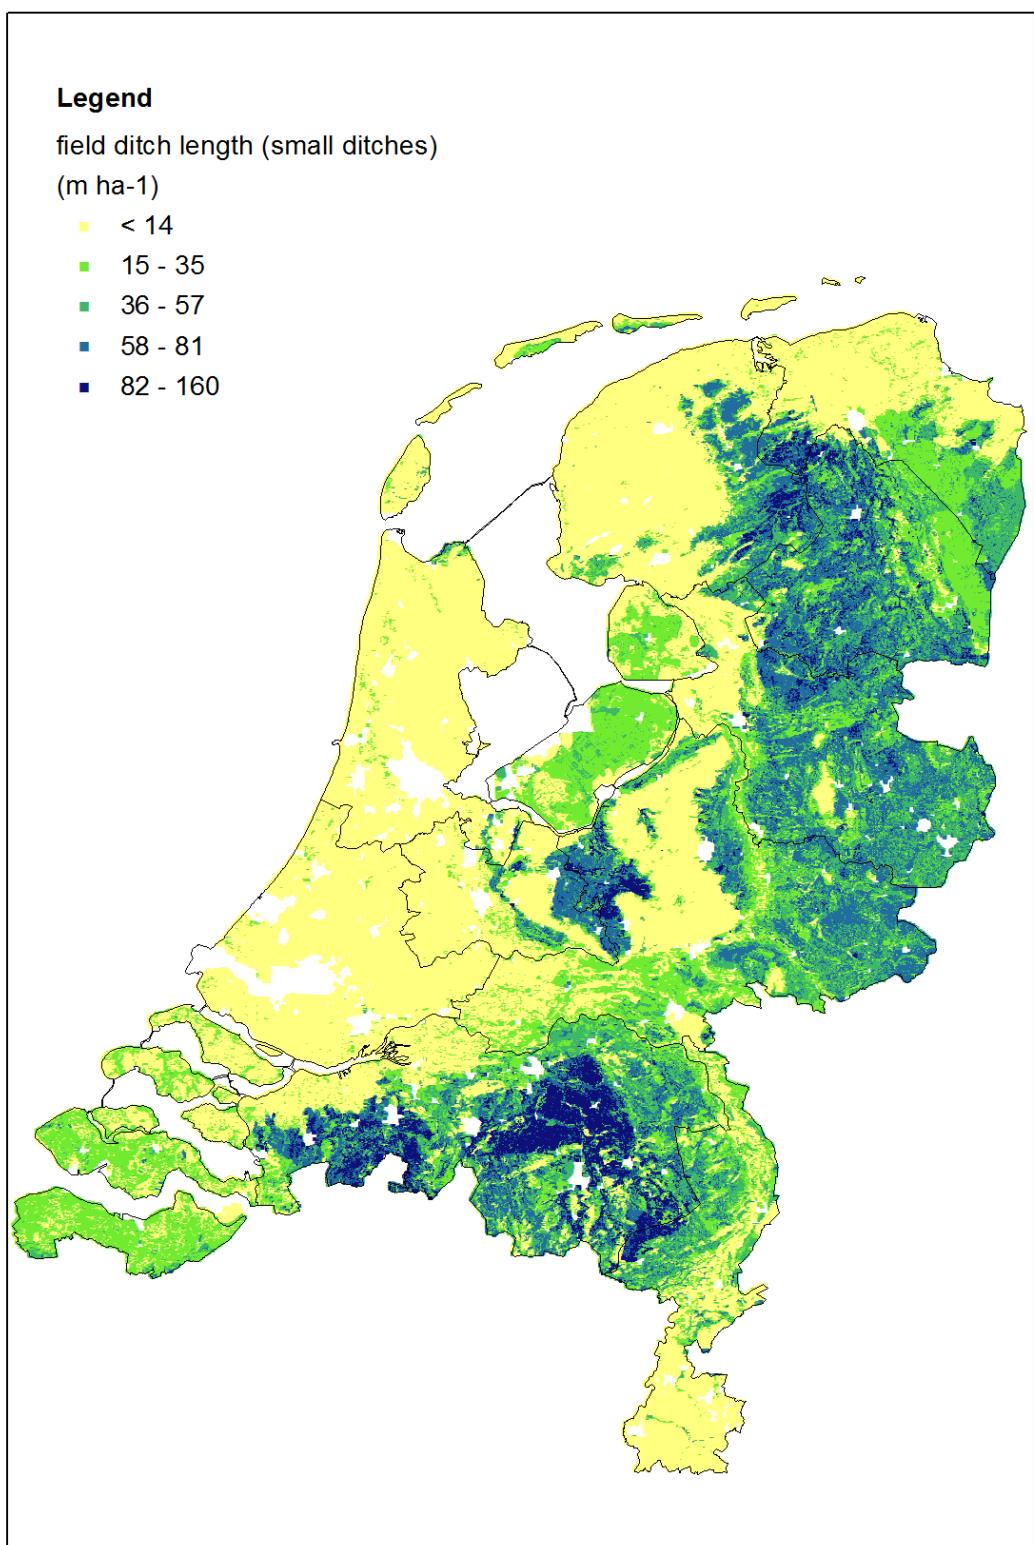

Map 1.1

Length of large field ditches with pipe drain outlet (m ha⁻¹).

Map 1.2

Length of medium size field ditches with pipe drain outlet (m ha⁻¹).

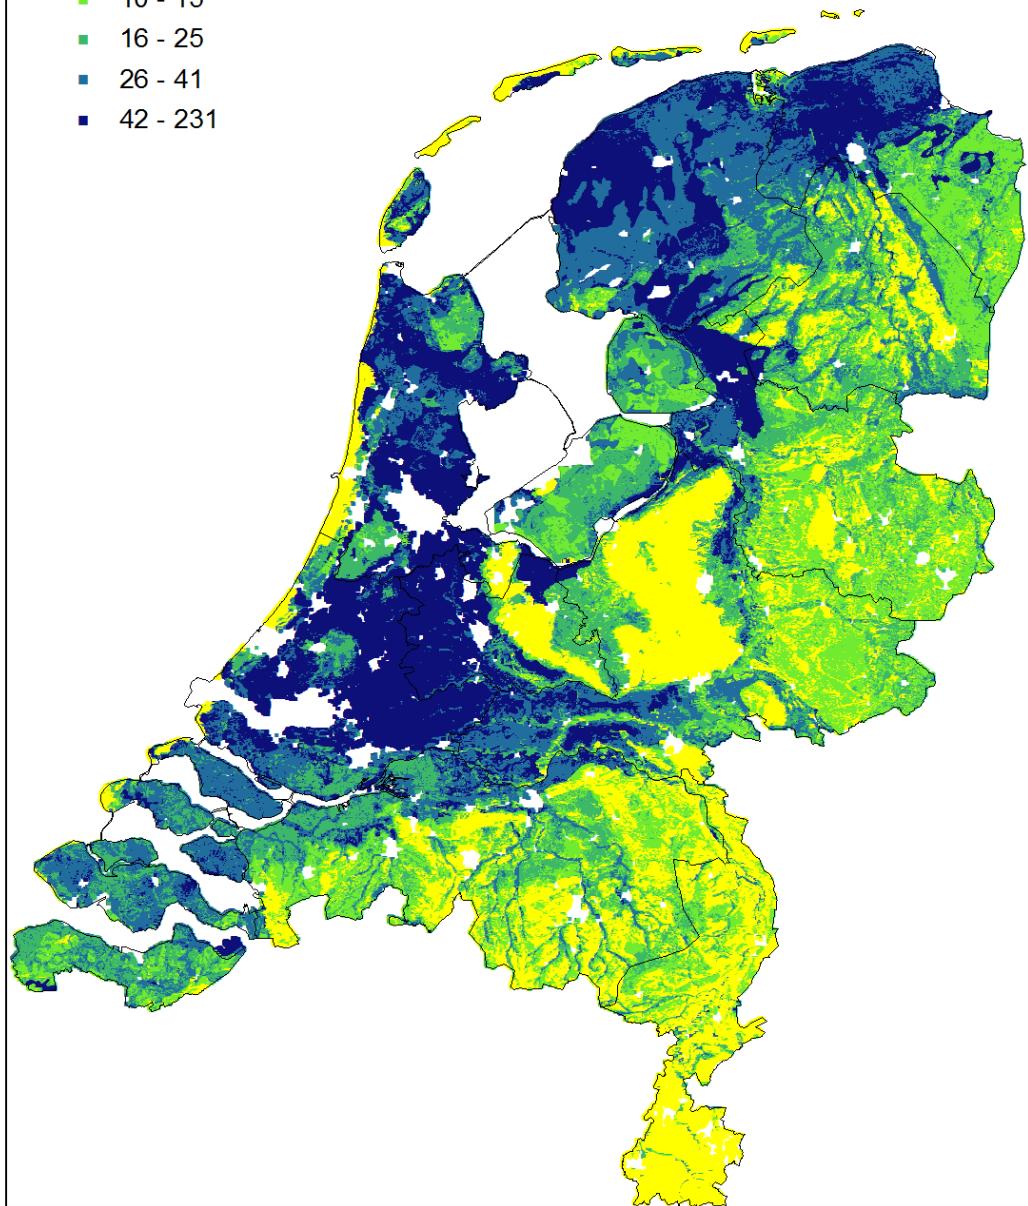

Map 1.3
Length of small field ditches with pipe drain outlet (m ha⁻¹).

Legend

water volume per unit area of land

($m^3 ha^{-1}$)

- 0.48 - 0.68
- 0.69 - 1.69

Map 1.5

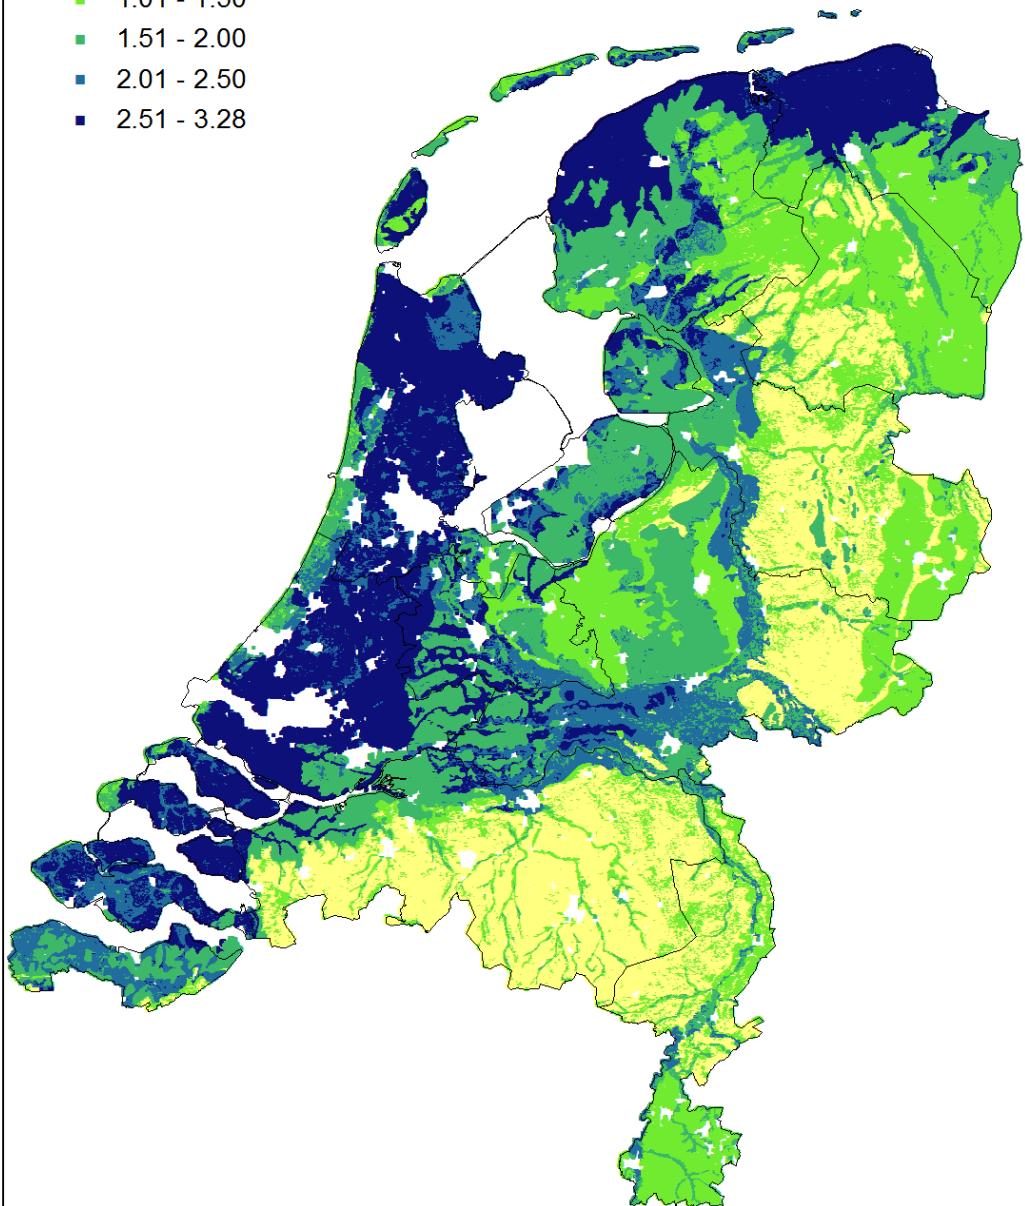

Average water volume in field ditches, per m ditch length ($\text{m}^3 \text{ per m}$).

Legend

average width of the water body

(m)

- 0.70 - 1.00
- 1.01 - 1.50
- 1.51 - 2.00
- 2.01 - 2.50
- 2.51 - 3.28

Map 1.6

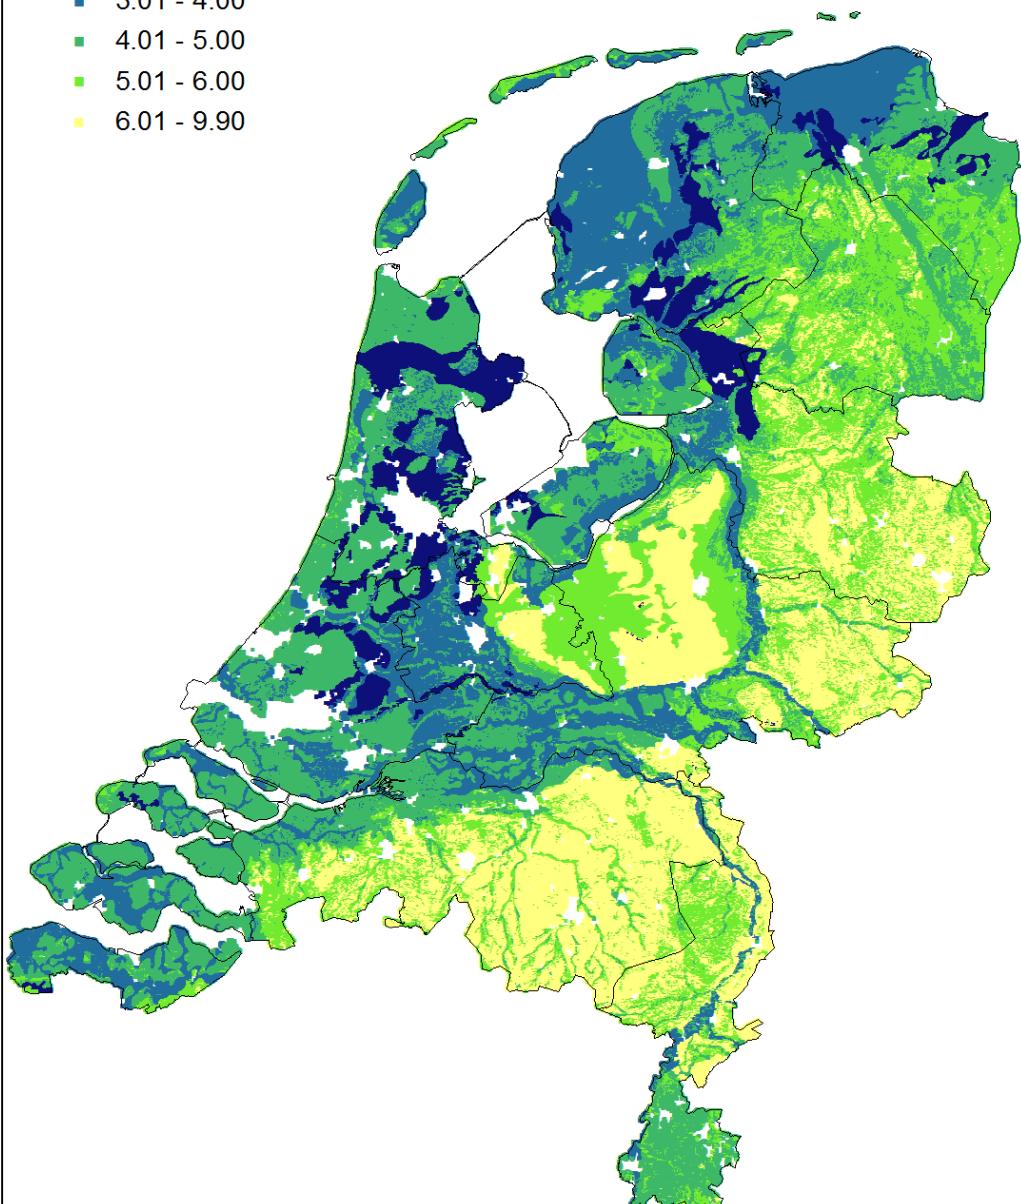

Average width of the water body in field ditches (m).

Legend

average ratio water width : water volume per unit length

(m⁻¹)

- 1.76 - 3.00
- 3.01 - 4.00
- 4.01 - 5.00
- 5.01 - 6.00
- 6.01 - 9.90

Map 1.7

Average ratio width of the water body : water volume per m ditch length (m⁻¹).

Appendix 2 Implementation drift reducing measures

Brongegevens NMI 3 : Implementatiegraden per combinatie van gewas, techniek en teeltvrije zone (per jaar, sector)

Klasse (alle 6 sectoren)

- Neerwaarts sputten (NMI code HERB for downwards spraying)
- Zijwaarts en opwaarts sputten (NMI code INFU for side- and upwards spraying)

Aanvulend voor de fruitteelt (windhaag)

- Kaal is windhaag in bladloos stadium (dormant stage of wind shield)
- Volblad is windhaag in volblad stadium – mei t/m oktober (full leaf stage of wind shield)

Toelichting: zie Appendix 3.

Appendix 3 Drift factors (standard ditch)

Tables in this appendix (for 1998, 2004, and 2008)

- fruit orchards
- flower bulbs
- tree nurseries
- vegetables
- arable crops
- livestock

Teeltvrije zone = crop free zone

The drift emission factors in this appendix apply to the “Dutch standard ditch” used in registration for calculating the exposure concentration in surface water (edge of field ditch). The standard ditch is not used in the calculations but was added to the NMI database for reference only.

For calculations with the NMI, a set of 66 drift emission factors is available for each combination. This comprises 3 ditch classes x 22 regions.

Document versie Drift cijfers NMI3 V3.docx dd 10-06-2011.

Appendix 4 Compounds and drainage group

Tables in this appendix

1. The number of substances per drainage group
2. Parent compounds with the drainage group number and the number of metabolites
3. Metabolites with the drainage group number
4. Substance properties (parents)

Section 3.1.3 describes the drainage group of the compounds in the database NMI 3. The list of compounds (active ingredients and metabolites) is included in this appendix.

1 The number of compounds per drainage group.

drainage group	Description	# parents	# metabolites
1	Model	36	12
2	Metamodel	143	21
3	emission = 0	109	
totaal		288	33

2 Parent compounds

4 Substance properties (parent compounds)

field name	description	units
RABnr	Unique reference to substance in Substance database	-
RabNaam	No input. For reference only.	-
RabNaamEng	No input. For reference only.	-
Casnr	No input. For reference only.	-
SpuitgroepType	either INFU (upward and sideward spraying) or NEER-WAARTS (downward spraying)	-
StofGroep	Product use in EU-substance list	-
Dampdruk_mPa	saturated vapour pressure	mPa
Molmassa_g_mol	molar mass	g mol ⁻¹
Oplosbaarheid_mg_l	solubility in water	mg L ⁻¹
DegT50_WS_d	half-life for degradation in water-sediment	d
DegT50_BODEM_d	half-life for degradation in soil	d
DegT50_WATER_d	half-life for degradation in water	d
DegT50_WATER_DINF_d	constant	d
DEGT50_GH_AIR_d	constant	d
DEGT50_GH_FLOOR_D	constant	d
DEGT50_GH_FOLIAGE_d	constant	d
Kom_L_kg	combined sorption coefficient	L kg ⁻¹
Kom_Basisch_L_kg	sorption coefficient for the conjugated base	L kg ⁻¹
Kom_Zuur_L_kg	sorption coefficient for the acidic molecule	L kg ⁻¹
phAfhangelijk_sorptie	switch denoting pH-dependent sorption	-
pKa	acid dissociation constant	-
LogKow	logarithm of the octanol-water partitioning coefficient	-
ETOX_OPWA_A_mg_L	lowest toxicity value for daphnia, algae and fish	(mg L ⁻¹)
ETOX_OPWA_C_mg_L	water quality standard Maximum Permissible concentration MPC (MTR)	(mg L ⁻¹)
ETOX_BODEM_A_mg_kg		mg a.i. kg dw ⁻¹
ETOX_BODEM_C_mg_kg		mg a.i. kg dw ⁻¹
ETOX_BODEM_2jr_mg_kg		mg a.i. kg dw ⁻¹
ETOX_BODEM_7jr_mg_kg		mg a.i. kg dw ⁻¹
ETOX_TERR_A_mg_kg	Dose causing 50% mortality in birds	(mg a.i. kg body weight ⁻¹ d ⁻¹)
ETOX_TERR_C_mg_kg	Dose causing no observed chronic effects on birds	(mg kg body weight ⁻¹ d ⁻¹)
datum	version date	-

Appendix 5 Crop data

Tables in this appendix

1. NMI crop area per crop group, in 3 survey years
2. Same as 1, with NMI crop codes
3. Crop interception fractions for spraying applications in arable crops (NMI 2)
4. Extrapolation of interception fractions in the NMI

1. NMI crop names, crop groups and crop area in 3 survey years (ha)

Crop	Crop group	Area (ha)		
		1998	2004	2008
Winter wheat	Akkerbouw (arable farming)	127673	117121	140463
Sugar beets		112551	97392	71590
Ware potatoes		84023	72543	69187
Starch potatoes		56936	51490	45989
Seed potatoes		39889	39706	36506

	Fruits: small fruits	boomkwekerijgewassen (except alley trees)	Roses, Conifers, Perannual plants, Fruit trees,	
		strawberries	Strawberries	all
		cranberries		
	Fruits: small fruits		-	Fungicide/insecticide treatments in year 1 and 2 after planting
Fruit crops [4]	fruit crops	All, except strawberries and cranberries (see [1])	Apple trees, Pear trees	All
				fungicide/insecticide (excepts for small fruits in year 1 and 2 after planting)
				herbicide other than downward directed (see [1])
	overige akkerbouwgewassen	hop, vlas	Flax	Fungicide/insecticide
Nursery tree crops [5]	sierteeltgewassen	Alley trees	Tree nursery	Fungicide/insecticide

Appendix 7 Substance flow in soilless cultivation systems

For soilless systems NMI 3 distinguishes between 3 combinations of application method and object treated (Main report, Section 3.2.6):

- A) Application along with the nutrient solution;
- B) Application to the crop canopy; with no exposure of the root compartment;
- C) Application to the crop canopy, pot plant cultivation; with direct exposure of the root compartment.

Scenario A) Application with the nutrient solution

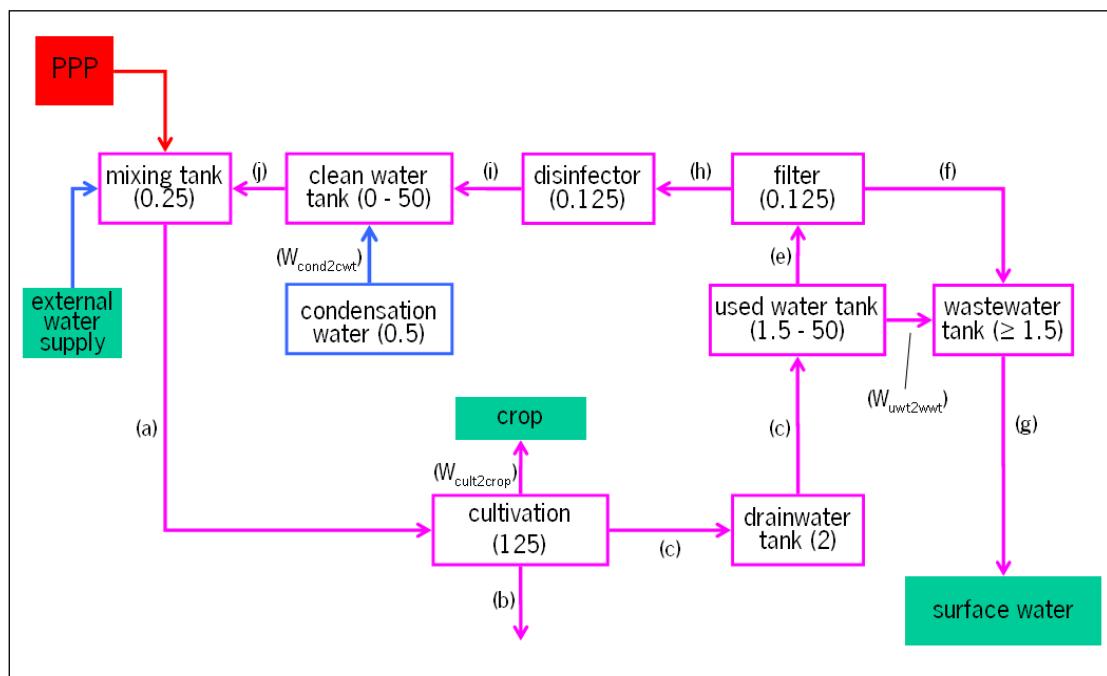

Figure 6.1

Flow chart for the nutrient solution and substance in the greenhouse substrate system applied along with the nutrient solution. Blue objects refer to water, red objects refer to the substance applied and the pink objects refer to the nutrient solution with the substance added. The values in brackets refer to the water volume in the tanks (m³). Green objects refer to external reservoirs and compartments.

Water fluxes

A schematic representation of the water flow system for this application scenario is given in Figure 6.1. The blue objects refer to water tanks/reservoirs and fluxes, the red objects refer to the substance applied and the pink objects refer to the nutrient solution with added substance. The values in brackets refer to the tank volume in m³. The green objects refer to external reservoirs and compartments.

Rain that falls on the roof of a greenhouse is collected in a basin and used for watering the crops. Before use, nutrients are added in the mixing tank. Pesticides are added to the nutrient solution in the mixing tank according to the application pattern (Figure 6.1). From the mixing tank the water is pumped to the plants (*a*) via the conductors and the substrate. Water and nutrients are partly taken up by the plants and the surplus is drained to the drain water collector tank (*c*). The supply rate exceeds the crop water demand in order to ensure continuous flow and a homogeneous solution within the system. The solution is pumped from the drain water collector tank to the used water tank, and can be reused as long as the sodium content does not exceed the sodium tolerance level of the crop.

The solution is pumped from the drain water collector tank to the used water tank (*d*). When the sodium level is below the tolerance level of the crop, the solution is filtered in the filter tank (*e*), disinfected in the disinfecter (*h*) and collected in the clean water tank (*i*) before it can recirculate via the mixing tank (*j*). When the sodium level has been exceeded, the solution is discharged to the surface water via the waste water tank (*g*). At these discharge events, part of the mass dissolved in the waste water resulting from filter cleaning is discharged via the waste water tank as well (*f*).

At the end of the growing period, the waste water tank may be (partly) filled with water and substance in solution. It is assumed that the waste water tank is emptied at the end of the growing period. In the NMI 3 the content of the waste water tank is discharged at 60 days after the last application event. During this 60 days period the substance concentration in the waste water tank decreases by degradation.

The condensation water collected from the inner side of the glass panels is added to the clean water tank.

If the available rainwater in the basin is depleted, additional tap water is added to the solution. The flux entering the system is rainwater and tap water lumped together. Fluxes leaving the system are;

1. uptake by the crops ($W_{cult2crop}$),
2. leakage out of the system (*b*),
3. filter cleaning water disposed (*f*),
4. discharge to the surface water (*g*).

Depending on sodicity and crop tolerance discharge of the water and substance solution occurs from the used water tank via the wastewater tank waste water tank ($W_{uwt2wwt}$). It is assumed that the greenhouse discharges directly to the surface water hence no sewage system is involved.

For the calculation of the water fluxes within the model greenhouse, three time series of daily water fluxes are used as input. These water fluxes are provided in step (a):

- Daily water uptake by the crop, $W_{cult2crop}$;
- Daily condensation water fluxes, $W_{cond2dim}$;
- Daily discharge to the waste water tank (which on its turn discharges to the surface water), $W_{uwt2wwt}$

These water fluxes are defined per hectare greenhouse surface area. The other water fluxes are derived from the three water fluxes above while preserving the water balance in the tanks and reservoirs. Most of the tanks and reservoirs are assumed to maintain a continuous maximum water volume. Only the water volumes in the used water tank and the clean water tank are allowed to fluctuate; V_{uwt} between 1.5 and 50 m³ and V_{cwt} between 0 and 50 m³, respectively. The relationships in Eq. (1) are used to derive the water fluxes :

$$\begin{aligned}
W_{(a)} &= R_{ws} W_{cult2crop} \\
W_{(b)} &= R_{ws} f_{cult} W_{cult2crop} \\
W_{(c)} &= W_{(d)} = W_{(a)} - W_{(b)} - W_{cult2crop} \\
W_{(e)} &= \max\left(0, W_{(c)} - W_{uwt2wwt} + \frac{V_{uwt} - \max(V_{uwt})}{dt}\right) \\
W_{(f)} &= f_{filt} W_{(e)} \\
W_{(g)} &= W_{uwt2wwt} + W_{(f)} \\
W_{(h)} &= (1 - f_{filt}) W_{(e)} \\
W_{(i)} &= W_{(h)} + W_{cond2dinf} \\
W_{(j)} &= \max\left(0, W_{(i)} + \frac{V_{cwt} - \max(V_{cwt})}{dt}\right)
\end{aligned} \tag{1}$$

W	water flux, with the symbols (a) to (j) referring to the fluxes as indicated in Figure 6.1 ($\text{m}^3 \text{ d}^{-1}$)
$W_{cult2crop}$	daily water uptake by the crop, provided in Step 1 ($\text{m}^3 \text{ d}^{-1}$)
$W_{cond2dinf}$	daily condensation water fluxes, provided in Step 1 ($\text{m}^3 \text{ d}^{-1}$)
$W_{uwt2wwt}$	daily discharge to the waste water tank, provided in Step 1 ($\text{m}^3 \text{ d}^{-1}$)
V_{uwt}	volume in the used water tank (m^3)
V_{cwt}	volume in the clean water tank (m^3)
R_{ws}	ratio water supply to crop demand (-)
f_{cult}	fraction leakage from cultivation tank (-)
f_{filt}	fraction loss due to regeneration of the filter (-)
dt	external internal time step (d, default 1 d)

The substrate and all the conducts between the mixing tank and the used water tank together are referred to as the cultivation tank. The fractions f_{cult} and f_{filt} are both equal to 0.01. The recirculation rate of the nutrient solution R_{ws} depends on the model crop used (Table 6.1).

Table 6.1

The recirculation rate of the nutrient solution (-).

Greenhouse model crop	R_{ws} (-)
Cucumber	1.33
Ficus	1.33
Sweet pepper	1.33
Phalaenopsis	1.33
Rose	1.50

Substance behaviour

After being applied to the mixing tank, the substance is transported with the water fluxes that flow through the greenhouse. In each reservoir in the greenhouse system, instant mixing of the substance is assumed.

Furthermore, the substance degrades according to first order degradation. The conservation equation in each reservoir is solved according to:

$$\frac{dV_i c_i}{dt} = \sum_{j=1}^n q_{j,i} c_j - \sum_{k=1}^m q_{i,k} c_i - V_i k_w c_i \quad (2)$$

where:

- V_i volume of water in tank/reservoir i (m),
- dt internal timestep (d)
- c_i concentration in tank/reservoir i (kg m^{-3})
- q_{ij} flux from tank/reservoir i to j ($\text{m}^3 \text{ d}^{-1}$)
- $\sum_{j=1}^n q_{j,i} c_j$ sum of all incoming fluxes from the tanks ($1 \leq j \leq n$)
- n number of incoming water fluxes
- $\sum_{k=1}^m q_{i,k} c_i$ sum over all the outgoing fluxes to the tanks ($1 \leq k \leq m$)
- m number of outgoing water fluxes
- k_w first order rate coefficient for transformation in water (d^{-1})

$$k_w = \frac{\ln(2)}{\text{DegT50}_{\text{water},gh}} \quad (3)$$

First order degradation is assumed in all identified tanks, including the substrate tank (Figures 6.1, 6.2, 6.3). Degradation rates are adjusted to reflect local temperatures (see at the end of this section). In some of the tanks the degradation rate is assumed to be independent of the substance. The used half-lives for these tanks are given in Table 6.2.

Table 6.2

Tanks/reservoirs defined in the greenhouse models for crops growing on artificial soil with the appropriate half-life for first-order degradation.

Tank/reservoir	Scenario	Degradation	Half-life (d)
Crop canopy	A, B, C	DegT50_GH_Foliage_d	10
Greenhouse floor	B, C	DegT50_GH_Floor_d	1000
Disinfecter #	A, B, C	DegT50_WATER_DINF_d	= DegT50_WATER_d
Mixing tank			
Cultivation tank			
Drainwater tank			
Used water tank	A, B, C	DegT50_WATER_d	Substance table
Filter			
Clean water tank			
Wastewater tank			
Condensation water ^{\$}	A	No substance	-
	B, C	DegT50_WATER_d	Substance table
Greenhouse air ^{\$}	B, C	DegT50_GH_Air_d	1000
Basin	A, B, C	External source	-
Crop (excl. canopy)	A, B, C	External sink	-
Surface water	A, B, C	External sink (→ Step c)	-

\$) Part of the reservoir "Condensation water and greenhouse air"

#) no separate conditions in the disinfecter are implemented

The cultivation tank and the drain water tank are located in the greenhouse where the temperature is assumed to be 20 °C. The temperature in the workroom where the other tanks are located is assumed to be 18 °C.

The total set of ordinary differential equations is solved numerically, by using the Euler method with a fixed time step of 1/360 d.

Root uptake

The uptake of the substance by the plant roots in substrate occurs along with the nutrients and the water. It is assumed that there is some barrier against uptake dependent on the octanol water partitioning coefficient. The daily mass taken up by the crop is defined by:

$$J_{cult2crop} = f_{tsc} W_{cult2crop} c_{cult} \quad (4)$$

$J_{cult2crop}$	daily mass uptake by the crop (kg a.i. d ⁻¹)
f_{tsc}	transpiration stream concentration factor (-)
$W_{cult2crop}$	daily water uptake by the crop (m ³ d ⁻¹)
c_{cult}	concentration in the cultivation tank (kg a.i. m ⁻³)

The transpiration stream concentration factor is derived according to Briggs et al. (1982) using the octanol water partitioning coefficient of the substance;

$$f_{tsc} = 0.784 \exp \left\{ \frac{-(\log(Kow) - 1.78)^2}{2.44} \right\} \quad (5)$$

f_{tsc}	transpiration stream concentration factor (-)
$\log(Kow)$	logarithm of the octanol water partitioning coefficient as listed in the substance table (-)

Scenario B) Application to the crop canopy; with no exposure of the root compartment.

Figure 6.2 gives the schematic representation of the water and substance fluxes in case the substance is applied to the crop by spraying or fogging/fumigation. The substrate is shielded, so there is no direct exposure of the root compartment. The shield surface is referred to as the greenhouse floor. The water flow system is similar to the water flow system in case the substance is applied with the nutrient solution. Contrary to Scenario A (Figure 6.1), the condensation water and the greenhouse air are considered as a single reservoir which may contain substance in solution and in the greenhouse air (vapour).

With respect to the substance behaviour, some additional storages and processes have to be taken into account compared to the applications along with the nutrient solution (Scenario A). Additional storages of substance are: the crop canopy, the condensation water and greenhouse air, and the greenhouse floor. Only via condensation water that flows from the glass surface area, the sidewalls and the roofs into the clean water tank, substance may enter the nutrient solution that is recycled within the greenhouse.

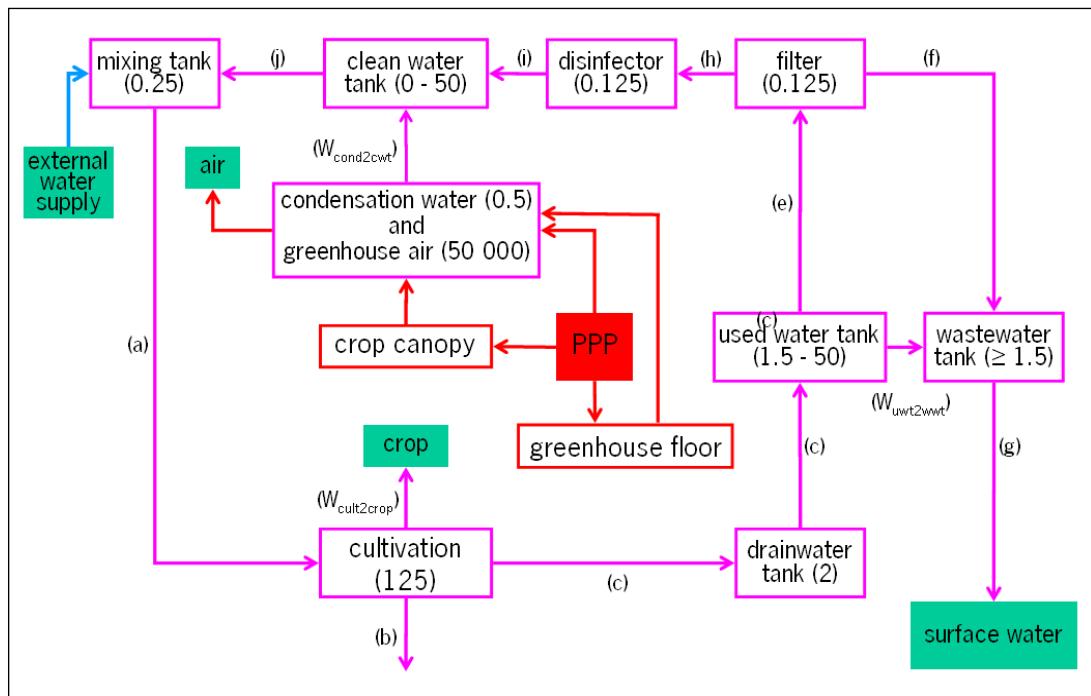

Figure 6.2

Flow chart for the nutrient solution and substance in the greenhouse substrate system applied by spraying, fogging or fumigating. The shield covering the substrate and the greenhouse soil is referred to as the greenhouse floor (see also Figure 6.1).

Application

During spraying, fogging or fumigation the substance is distributed between the plant leaves, the greenhouse air and the greenhouse floor. The initial distribution over the crop canopy, the greenhouse air and condensation water, and the greenhouse floor is estimated according to:

$$\begin{aligned}
 A_{p,t=0} &= f_{\text{int}} A 10^{-4} \\
 A_{al,t=0} &= f_{al} A 10^{-4} \\
 A_{f,t=0} &= (1 - f_{\text{int}} - f_{al}) A 10^{-4}
 \end{aligned} \tag{6}$$

A	the nominal rate for a single application (kg a.i. ha^{-1})
$A_{p,t=0}$	areic mass deposited at the plants, at $t = 0$ (kg a.i. m^2)
f_{int}	fraction of the application rate that is intercepted by the crop (-)
$A_{al,t=0}$	areic mass that is volatilized into the greenhouse air (kg a.i. m^2)
$A_{f,t=0}$	areic mass deposited at the greenhouse floor, at $t = 0$ (kg a.i. m^2).
f_{al}	fraction of the application rate that has been volatilized into the greenhouse air (-).
10^{-4}	factor to convert ha to m^2

The fractions f_{int} and f_{al} depend on the application type and the growth stage of the crop. Since no detailed information is available on the relationship between application type, growth stage and these fractions, these are constants, i.e. the application loss $f_{al} = 0.03$ and the interception fraction $f_{\text{int}} = 0.9$ independent of the growth stage.

Processes on the crop canopy and the greenhouse floor

Continuous exchange of substance occurs between the crop canopy and the greenhouse air, and between the greenhouse floor and the greenhouse air. The following processes are considered:

- Volatilization
- Deposition

The exchange between the crop canopy and the greenhouse air depends on the concentration gradient between the laminar boundary layer directly above the crop canopy and the greenhouse air, and the areic mass on the plant. The conservation equation for the areic mass on plants reads:

$$\frac{dA_p}{dt} = J_{d,p} - J_{v,p} \quad (7)$$

A_p	areic mass on the plant (kg a.i. m ²)
$J_{d,p}$	deposition rate on the plant, per unit of cultivated area (kg a.i. m ² d ⁻¹)
$J_{v,p}$	volatilisation rate from the plant (kg a.i. m ² d ⁻¹)
dt	internal time step (d)

The deposition rate on the plant is given by:

$$J_{d,p} = LAI \frac{c_{air} - c_p}{R_{air}} \quad (c_{air} > c_p) \quad (8)$$

$$J_{d,p} = 0 \quad (c_{air} \leq c_p)$$

$J_{d,p}$	deposition rate on the plant (kg a.i. m ² d ⁻¹)
LAI	Leaf Area Index of the crop (-)
c_p	concentration in the gas phase at the crop canopy (kg a.i. m ⁻³)
c_{air}	concentration in the greenhouse air (kg a.i. m ⁻³)
R_{air}	laminar boundary layer resistance (= 1.16 10 ⁻³ d m ⁻¹)

The Leaf Area Index of the crop is assumed to be 5, independent of the greenhouse model crop or development stage.

The volatilization from the plant is given by:

$$J_{v,p} = \frac{A_p}{A_r} \frac{c_p - c_{air}}{R_{air}} \quad (c_p > c_{air}) \quad (9)$$

$$J_{v,p} = 0 \quad (c_p \leq c_{air})$$

$J_{v,p}$	volatilization rate from the plant (kg a.i. m ² d ⁻¹)
A_p	areic mass on the plant (kg a.i. m ²)
A_r	reference mass (= 10 ⁴ kg a.i. m ²)
c_p	concentration in the gas phase at the crop canopy (kg a.i. m ⁻³)
c_{air}	concentration in the greenhouse air (kg a.i. m ⁻³)
R_{air}	laminar boundary layer resistance (d m ⁻¹)

According to (Jacobs *et al.*, 2007), the laminar boundary layer resistance is estimated to be equal to $1.16 \cdot 10^{-3}$ (d m^{-1}).

The concentration in the gas phase at the canopy is assumed to depend on the saturated vapour pressure, according to:

$$c_p = \frac{MM P_{\text{sat}} 10^{-6}}{R T_{\text{gh}}} \quad (10)$$

c_p	concentration in the gas phase at the crop canopy (kg a.i. m^{-3})
MM	molar mass (g mol^{-1})
P_{sat}	saturated vapour pressure (mPa)
R	molar gas constant ($8.314 \text{ J mol}^{-1} \text{ K}^{-1}$)
T_{gh}	temperature in the greenhouse (K)
S	solubility in water (mg l^{-1})
10^{-6}	factor to convert mPa to Pa and (g mol^{-1}) to (kg mol^{-1})

The saturated vapour pressure is adjusted to reflect local temperature (see at the end of this section).

The exchange between the greenhouse floor and the greenhouse air depends on the concentration gradient between the greenhouse floor and the greenhouse air, and the areic mass on the greenhouse floor. The conservation equation for the areic mass on the greenhouse floor reads:

$$\frac{dA_f}{dt} = J_{d,f} - J_{v,f} \quad (11)$$

A_f	areic mass on the greenhouse floor (kg a.i. m^2)
$J_{d,f}$	deposition rate on the greenhouse floor ($\text{kg a.i. m}^2 \text{ d}^{-1}$)
$J_{v,f}$	volatilisation rate from the greenhouse floor ($\text{kg a.i. m}^2 \text{ d}^{-1}$)
dt	internal timestep (d)

The deposition on the greenhouse floor is given by:

$$J_{d,f} = \frac{c_{\text{air}} - c_f}{R_{\text{air}}} \quad (c_{\text{air}} > c_f) \quad (12)$$

$$J_{d,f} = 0 \quad (c_{\text{air}} \leq c_f)$$

$J_{d,f}$	deposition rate on the greenhouse floor ($\text{kg a.i. m}^2 \text{ d}^{-1}$)
c_f	concentration in the gas phase at the greenhouse floor (kg a.i. m^{-3})
c_{air}	concentration in the greenhouse air (kg a.i. m^{-3})
R_{air}	laminar boundary layer resistance (d m^{-1}), being $1.16 \cdot 10^{-3}$ (Jacobs <i>et al.</i> , 2007)

The volatilization from the greenhouse floor is given by:

$$J_{v,f} = \frac{A_f}{A_r} \frac{c_f - c_{\text{air}}}{R_{\text{air}}} \quad (c_f > c_{\text{air}}) \quad (13)$$

$$J_{v,f} = 0 \quad (c_f \leq c_{\text{air}})$$

$J_{v,f}$	volatilization rate from the greenhouse floor (kg a.i. m ² d ⁻¹)
A_f	areic mass on the greenhouse floor (kg a.i. m ²)
A_r	reference mass (= 10 ⁴ kg a.i. m ²)
c_p	concentration in the gas phase at the greenhouse floor (kg a.i. m ⁻³)
c_{air}	concentration in the greenhouse air (kg a.i. m ⁻³)
R_{air}	laminar boundary layer resistance (d m ⁻¹).

The concentration in the gas phase at the greenhouse floor is assumed equal to the concentration at the crop canopy given by Eq. 10;

$$c_f = c_p \quad (14)$$

c_f	concentration in the gas phase at the greenhouse floor (kg a.i. m ⁻³)
c_p	concentration in the gas phase at the crop canopy (kg a.i. m ⁻³)

Partitioning between greenhouse air and condensation water

The conservation equation for the greenhouse air is given by:

$$\frac{dM_{ghair}}{dt} = (J_{v,p} + J_{v,f} - J_{d,p} - J_{d,f}) \quad (15)$$

M_{ghair}	mass in the greenhouse air and condensation water per unit area of greenhouse cultivation area (kg a.i. m ²)
$J_{v,p}$	volatilisation rate from the plant (kg a.i. m ² d ⁻¹)
$J_{v,f}$	volatilisation rate from the greenhouse floor (kg a.i. m ² d ⁻¹)
$J_{d,p}$	deposition rate on the plant (kg a.i. m ² d ⁻¹)
$J_{d,f}$	deposition rate on the greenhouse floor (kg a.i. m ² d ⁻¹)
dt	internal time step (d)

The partitioning of the substance between the greenhouse air and the condensation water is described with the Henry coefficient, which can be calculated from the substance properties:

$$K_H = \frac{c_{air}}{c_w} = \frac{0.001P_{sat}MM}{RT_{gh}S} \quad (16)$$

K_H	dimensionless Henry coefficient, at T_{gh} (-)
c_{air}	concentration in the greenhouse air (kg a.i. m ⁻³)
c_w	concentration in the condensation water (kg a.i. m ⁻³)
P_{sat}	saturated vapour pressure, at T_{gh} (mPa)
MM	molar mass (g mol ⁻¹)
R	molar gas constant (8.314 J mol ⁻¹ K ⁻¹)
T_{gh}	temperature in the greenhouse (K)
S	solubility in water, at T_{gh} (mg l ⁻¹)
0.001	factor to convert mPa to Pa.

Both the saturated vapour pressure and solubility are adjusted for the temperature in the greenhouse (see at the end of this section).

The total mass in the condensation water and greenhouse air is given by:

$$M_{ghair} = (V_{air}c_{air} + V_c c_w) 10^{-4} \quad (17)$$

M_{ghair}	mass in the greenhouse air and condensation water per m ² area of cultivated area (kg a.i. m ⁻²)
V_{gh}	volume of the cultivation part of the greenhouse per ha area of cultivated area (50000 m ³ ha ⁻¹)
c_{air}	concentration in the greenhouse air (kg a.i. m ⁻³)
V_c	volume of the condensation water per unit ha of cultivated area (0.53 m ³ ha ⁻¹)
c_w	concentration in the condensation water (kg a.i. m ⁻³)
10^{-4}	factor for conversion from ha to m ² .

Since $c_w = c_{air} / K_H$, Eq. 17 can be rewritten:

$$c_{air} = \frac{M_{ghair}}{V_{gh} + V_c / K_H} 10^4 \quad (18)$$

c_{air}	concentration in the greenhouse air (kg a.i. m ⁻³)
M_{ghair}	mass in the greenhouse air and condensation water per m ² cultivated area (kg a.i. m ⁻²)
V_{gh}	volume of the cultivation part of the greenhouse per ha cultivated area (50000 m ³ ha ⁻¹)
V_c	volume of the condensation water per unit cultivated area (0.53 m ³ ha ⁻¹)
K_H	dimensionless Henry coefficient (-)

The volume of the cultivation part of the greenhouse $V_{gh} = 50000$ m³ per ha cultivated area, whereas the volume of condensation water (V_c) is estimated to be 0.53 m³ per ha cultivated area.

Once the mass equations to calculate M_{ghair} have been solved (Eq. 15), c_{air} can be derived using Eq. 18, and the concentration in the condensation water (c_w) can then be derived using Eq. 16.

Similar to the applications along with the nutrient solution there is first order degradation in all identified tanks, including the surface at the greenhouse floor, the greenhouse air, the condensation water, and the substance on the crop canopy. In some of the tanks the degradation rate is assumed constant and independent of the substance. The used half-lives for these tanks are given in Table 6.2. Degradation rates are adjusted for local temperature where necessary (see at the end of this section).

The temperature in the cultivation tank and the drain water tank located in the greenhouse is assumed to be 20 °C. The temperature in the workroom with the other tanks is assumed to be 18 °C. Also similar to the applications with the nutrient solution, Eq. (2) is used to calculate the uptake concentration as compared to the concentration of substance in the recirculation water.

Emission to the outside air

Emission of substance towards air occurs through transport with the ventilated greenhouse air. The daily-emitted mass of substance via the greenhouse air towards the air outside depends on the air exchange rate of the greenhouse and the concentration in the greenhouse air:

$$J_{2air} = N_{vent} V_{gh} c_{air} \quad (19)$$

J_{2air}	nominal emission rate from the greenhouse air towards the outside air, per ha cultivated area ($\text{kg ha}^{-1} \text{ d}^{-1}$)
N_{vent}	air exchange rate of the greenhouse (d^{-1})
V_{gh}	volume of the cultivation part of the greenhouse per ha cultivated area ($\text{m}^3 \text{ ha}^{-1}$)
C_{air}	concentration in the greenhouse air (kg a.i. m^{-3})

The air exchange rate is estimated to be 50 d^{-1} . The nominal emission rate J_{2air} can be multiplied with the application rate and cumulated over 365 days, to obtain the emission to air per ha greenhouse.

The substance in the condensation water flows into the greenhouse recirculation system via the clean water tank. The residues in the recirculation water may ultimately be discharged to surface water.

Mass balances are solved for each tank on the basis of daily water fluxes, substance characteristics and application timing. The set of ordinary differential equations is solved numerically, by using the Euler method with a fixed time step of 1/360 d.

C) Application to the crop canopy; with direct exposure of the root compartment.

Figure 6.3 gives a schematic representation of the water and substance fluxes in case the substance is applied to the crop by spraying, fogging or fumigation, with direct exposure of the root compartment. This system refers mainly to flooded tables. The scheme is applicable to the cultivation of pot plants where the individual pots are not covered by plastic. The water flow system is similar to the flow system of the other application scenarios for soilless cultivation. The system differs from the shielded roots system in that direct application to the recirculation water forms an additional source of substance that may be emitted to the surface water.

Pesticide supply

During spraying, fogging or fumigation the substance is distributed between the plant leaves, the substrate, recirculation water and the greenhouse air. The initial distribution over the crop canopy ($M_{int,appl}$), the greenhouse air and condensation water ($M_{ghair,appl}$), the substrate ($M_{sub,appl}$) and the cultivation reservoir ($M_{cult,appl}$) is estimated according to:

$$\begin{aligned} M_{int,appl} &= f_{int} M_{appl} \\ M_{ghair,appl} &= f_{air} M_{appl} \\ M_{sub,appl} &= (1 - f_{int} - f_{air}) P_{pot} M_{appl} \\ M_{cult,appl} &= (1 - f_{int} - f_{air})(1 - P_{pot}) M_{appl} \end{aligned} \quad (20)$$

where M_{appl} (kg d^{-1}) is the total applied mass, f_{int} (-) is the fraction of the total mass that is intercepted by the greenhouse crop, f_{air} (-) is the fraction of the total applied mass that volatilizes into the greenhouse air and P_{pot} (-) is the fraction of the production surface area covered with pots. Similar to the root-shielded application scenario, $f_{air} = 0.03$ and $f_{int} = 0.9$, independent of the growth stage and application technique. $P_{pot} = 0.9$.

Continuous exchange of substance occurs between the crop canopy, the substrate, the recirculation water and the greenhouse air. This exchange depends on the concentration gradient between the greenhouse air and the concentration directly above the canopy, substrate and recirculation water;

$$\begin{aligned}
J_{canop2air} &= A_{gh} f_{ex_canopy} \frac{C_{g,0} - C_{air}}{R_{air}}; \\
J_{sub2air} &= A_{gh} f_{ex_sub} \frac{C_{g,sub} - C_{air}}{R_{air}} \\
J_{cult2air} &= A_{gh} f_{ex_cult} \frac{C_{g,cult} - C_{air}}{R_{air}}
\end{aligned} \tag{21}$$

where $J_{canop2air}$ (kg d^{-1}) is the mass exchange rate between the crop canopy and greenhouse air, $J_{sub2air}$ (kg d^{-1}) the mass exchange rate between the substrate and greenhouse air, $J_{cult2air}$ (kg d^{-1}) the mass exchange rate between recirculation water and greenhouse air, R_{air} (d m^{-1}) is the laminar boundary layer resistance, being $1.16 \cdot 10^{-3}$ (Jacobs *et al.*, 2007). A_{gh} is the surface of the greenhouse, which is $10,000 \text{ m}^2$.

The concentration in the gas phase at the canopy ($C_{g,0}$, kg m^{-3}) is calculated according to Eq. (10).

The concentration in the gas phase at the substrate surface is derived from the formula given by Smit *et al.*, 1997):

$$C_{g,sub} = \frac{C_{sub}}{(\rho_{soil} f_{om} K_{om} + \theta_{liq}) / K_H + \theta_{gas}} \tag{22}$$

Where C_{sub} is the concentration of the substance in the substrate (soil, kg m^{-3}), ρ_{soil} is the bulk dry density of soil (1000 kg/m^3), f_{om} (-) is the fraction organic matter in the substrate (a value of 0.1 is assumed), K_{om} ($\text{m}^3 \text{ kg}^{-1}$) is the sorption constant to organic matter, Θ_{liq} and Θ_{gas} are the volume fractions of liquid resp. gas in the soil (values of 0.4 and 0.2 are assumed resp.; the value of Θ_{gas} is not critical), and K_H is the dimensionless Henry coefficient (Eq. 16).

The concentration in the substrate is equal to the mass in the substrate divided by the mass of substrate:

$$C_{sub} = M_{sub} / S_{cult} \tag{23}$$

where M_{sub} is the substance mass in the substrate in the pot plants and S_{cult} is the mass of substrate corresponding to 1 hectare of tables (900,000 kg).

Substituting Eq. (23) into Eq. (22) results in:

$$C_{g,sub} = \frac{\rho_{soil} M_{sub}}{S_{cult} \{ \rho_{soil} f_{om} K_{om} + \theta_{liq} \} / K_H + S_{cult} \theta_{gas}} \tag{24}$$

The concentration in the gas phase at the cultivation surface, $C_{g,cult}$ is given by:

$$C_{g,cult} = K_H \frac{M_{cult}}{V_{cult} + f_{om} K_{om} S_{cult}} \tag{25}$$

where M_{cult} (kg) is the substance mass in the cultivation tank, V_{cult} (m^3) is the volume of the cultivation tank, i.e. 125 m^3 , and S_{cult} (kg) is the mass of substrate (i.e. soil) in the cultivation tank, i.e. 900,000 kg.

Equilibrium between pore water and substrate is assumed. Equation 25 reflects that the gaseous concentration above the culture water is governed by the ‘freely dissolved’ i.e. non-sorbed concentration of the substance. Sorption of the substance to organic matter in the substrate in the pot plants will result in a decrease of the concentration in the gas phase above the culture water.

The exchange fractions $f_{ex,canopy}$, $f_{ex,sub}$ and $f_{ex,cult}$ depend on the direction of the concentration gradient:

$$\begin{aligned} f_{ex,canopy} &= \begin{cases} M_{canop} / M_{ref} & \text{for } C_{g,0} \geq C_{air} \text{ and } M_{canop} > 0 \\ LAI & \text{for } C_{g,0} < C_{air} \end{cases} \\ f_{ex,sub} &= \begin{cases} M_{sub} / M_{ref} & \text{for } C_{g,sub} \geq C_{air} \text{ and } M_{floor} > 0 \\ P_{pot} & \text{for } C_{g,sub} < C_{air} \end{cases} \\ f_{ex,cult} &= \begin{cases} (1 - P_{pot})M_{cult} / M_{ref} & \text{for } C_{g,cult} \geq C_{air} \text{ and } M_{cult} > 0 \\ (1 - P_{pot}) & \text{for } C_{g,cult} < C_{air} \end{cases} \end{aligned} \quad (26)$$

where M_{canop} (kg) refers to the mass on the crop canopy, M_{sub} (kg) refers to the mass on the substrate, M_{ref} (kg) refers to the reference mass, which is set to 1 kg, LAI (-) refers to the Leaf Area Index of the crop. The LAI is assumed to be 5, independent of the crop type or development stage.

Once the mass equations to calculate M_{ghair} have been solved (Eq. 20), the concentration in the greenhouse air can be calculated. From this the concentration of the substance in the condensation water, C_{cond} (kg m^{-3}), is calculated using the air-water partitioning coefficient according to Eq. (16) and (18), and using volumes of the cultivation part of the greenhouse and of the condensation water of 50,000 m^3 and 0.53 m^3 resp.

The substance in the condensation water flows into the greenhouse recirculation system via the clean water tank. Residues in the recirculation water may ultimately be discharged to surface water.

Mass balances are solved for each tank on the basis of daily water fluxes, substance characteristics and application timing. The set of ordinary differential equations is solved numerically, by using the Euler method with a fixed time step of 1/360 d.

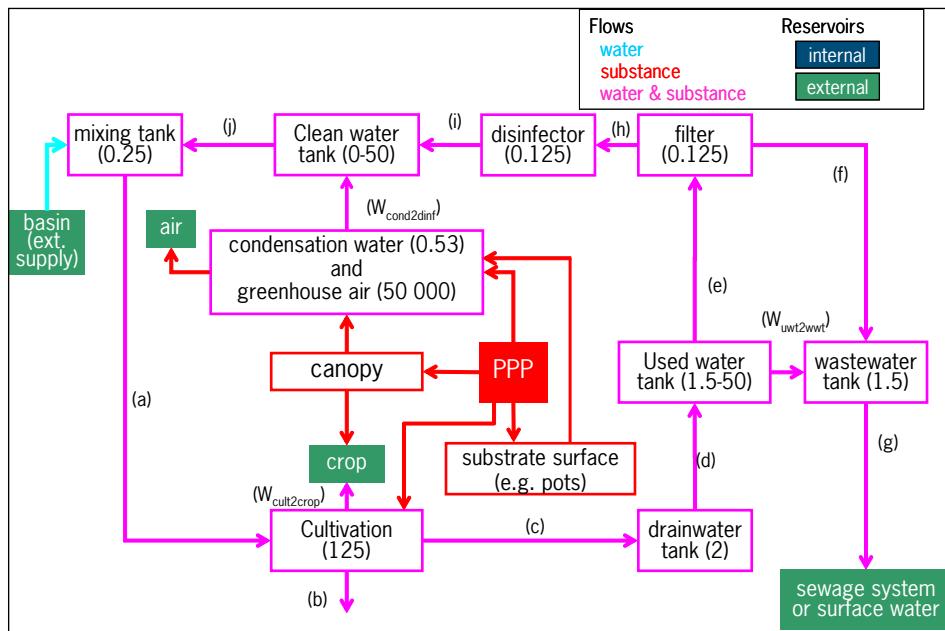

Figure 6.3

Flow chart for water and substance for substrate system and application to the crop with direct exposure of the root compartment. The blue arrow refers to clean water, the red tank and arrows refer to substance flow or tank and the pink tanks and arrows refer to water with substance. The values in brackets refer to the volume of tanks in m^3 .

Influence of temperature on degradation rates, solubility and vapour pressure

The influence of temperature on degradation rates is given by the Arrhenius equation:

$$DegT50_{water,gh} = f_T \ DegT50_{water,ref} \quad (27)$$

$$f_T = \exp\left(\frac{-\Delta H_T}{R}\left(\frac{1}{T_{ref}} - \frac{1}{T_{gh}}\right)\right) \quad (28)$$

$DegT50_{water,gh}$	transformation half-life in the greenhouse tank (d)
$DegT50_{water,ref}$	nominal transformation half-life of the substance in water as listed in the substance table (d)
ΔH_T	molar enthalpy of transformation ($J \ mol^{-1}$), (default 65400 $J \ mol^{-1}$)
R	molar gas constant ($J \ mol^{-1} \ K^{-1}$), (value 8.314 $J \ mol^{-1} \ K^{-1}$)
T_{ref}	reference temperature (K), (value 293.15 K = 20 °C)
T_{gh}	temperature in the greenhouse tank (K)

Vapour pressure (including saturated vapour pressure) is adjusted for the temperature in the greenhouse, using for all substances the default molar enthalpy of vaporisation;

$$P_{sat} = \frac{P_{sat,ref}}{f_T} \quad (29)$$

$$f_T = \exp\left(\frac{-\Delta H_{vol}}{R}\left(\frac{1}{T_{ref}} - \frac{1}{T_{gh}}\right)\right) \quad (30)$$

with

f_T	temperature correction factor (-)
$P_{sat,ref}$	the saturated vapour pressure of the substance at reference temperature (mPa)
P_{sat}	the saturated vapour pressure (mPa)
ΔH_{vol}	molar enthalpy of volatilisation ($J \text{ mol}^{-1}$) (95000 J mol^{-1})
R	molar gas constant ($J \text{ mol}^{-1} \text{ K}^{-1}$) (value $8.314 \text{ J mol}^{-1} \text{ K}^{-1}$)
T_{ref}	reference temperature (K) (value $293.15 \text{ K} \equiv 20 \text{ }^{\circ}\text{C}$)
T_{gh}	temperature in the greenhouse (K)

The solubility in water is adjusted for the temperature in the greenhouse, using for all substances the default molar enthalpy of dissolution in water;

$$S = \frac{S_{ref}}{f_T} \quad (31)$$

$$f_T = \exp\left(\frac{-E_{dis}}{R} \left(\frac{1}{T_{ref}} - \frac{1}{T_{gh}}\right)\right) \quad (32)$$

f_T	temperature correction factor (-)
S_{ref}	the substance solubility in water at reference temperature (mg L^{-1})
S	the solubility in water (mg L^{-1})
E_{dis}	molar enthalpy of dissolution ($J \text{ mol}^{-1}$), (27000 J mol^{-1})
R	molar gas constant ($J \text{ mol}^{-1} \text{ K}^{-1}$) (value $8.314 \text{ J mol}^{-1} \text{ K}^{-1}$)
T_{ref}	reference temperature (K) (value $293.15 \text{ K} \equiv 20 \text{ }^{\circ}\text{C}$)
T_{gh}	temperature in the greenhouse (K)

Appendix 8 Review of the scientific panel (in Dutch)

Afbakening

De taak van de wetenschappelijke begeleidingsgroep (wbg) was in de praktijk beperkt tot discussies op basis van Powerpoint presentaties vanuit de projectgroep over de conceptuele opzet van de NMI en tot het beoordelen van het rapport 'Dutch Environmental Risk Indicator for Pesticides – NMI-3'. De begeleidingsgroep speelde dus geen rol in de kwaliteitsborging van de databases en van de software waarmee de NMI-3 berekeningen worden uitgevoerd. De verantwoordelijkheid voor deze borging ligt zodoende bij de auteurs van het rapport. Verder zijn in de rapportage geen voorbeeldberekeningen opgenomen. Om deze reden kan de werkgroep geen uitspraak doen over de plausibiliteit van de resultaten die met de NMI-3 verkregen worden.

Proces

De leden van de wbg zijn een aantal keren bij elkaar geweest. Tijdens deze bijeenkomsten is gedetailleerd commentaar geleverd, dat door de auteurs in het algemeen goed verwerkt is. De wbg maakt zich wel enige zorgen over de afstemming van de rapportage en de software. Op detailniveau zijn namelijk zeer recentelijk (nadat de definitieve berekeningen zijn opgeleverd) nog aanpassingen van de rapportage uitgevoerd. Onduidelijk is daarom of de resultaten van de definitieve berekeningen en dit rapport met elkaar in overeenstemming zijn; de begeleidingsgroep kan daarom op dit punt geen garanties afgeven (zie ook voorgaand punt).

Alleen geschikt voor berekenen trend

Uit de rapportage blijkt duidelijk dat de NMI-3 uitsluitend geschikt is voor het berekenen van de trend van de belasting van het oppervlaktewater. Het instrumentarium is met nadruk niet geschikt voor het berekenen van:

- de zogenoemde 'distance to target',
- de absolute waarde van de 'exposure toxicity ratio', en
- de berekening van het risico voor het waterleven.

Deze beperkingen zijn ook aangegeven in het rapport.

Dat dit niet mogelijk is, hangt met name samen met de wijze waarop de concentratie in het oppervlaktewater wordt berekend. In de NMI-3 wordt per toepassingen alle gewasbeschermingsmiddel als het ware in 6405 grote vaten gemengd oppervlaktewater gestopt. Het geschatte volume van deze vaten heeft slechts zijdelings een relatie met het werkelijke volume, en ook kan ervan worden uitgegaan dat het water in werkelijkheid niet volledig is gemengd. De zo verkregen concentratie heeft daardoor geen fysische betekenis. Om deze reden is vergelijking met een norm in absolute zin dus niet zinvol.

Milieubelasting van verschillende bronnen niet optellen

Binnen de NMI-3 worden verschillende modellen gebruikt om de emissie naar het oppervlaktewater te berekenen. Aangezien deze modellen een verschillende grondslag hebben, kan de milieubelasting vanuit de verschillende routes niet bij elkaar worden opgeteld (deze beperking is ook aangegeven in het rapport).

Belangrijk element hierbij is dat voor de verschillende routes om redenen van de beschikbaarheid van gegevens andere percentielen zijn gebruikt. Voor de akkerbouw is bijvoorbeeld het 90-percentiel gebruikt, voor de fruitteelt het 70-percentiel en voor de kassen is het percentiel niet bekend.

Bijdrage drainage, atmosferische depositie en drift niet goed te bepalen

In de NMI-3 wordt de bijdrage van drift en atmosferische depositie opgeteld en die van drainage apart berekend. Per toepassing en rekenplot wordt alleen de emissieroute die de hoogste bijdrage aan de milieubelasting levert meegenomen, de andere wordt op nul gezet. Dit was een pragmatische oplossing, omdat volledige integratie van de NMI-3 en GeoPEARL niet mogelijk en wenselijk was. In werkelijkheid komen de bijdragen van de verschillende blootstellingsroutes bovenop de concentratie die dan al door de overige blootstellingsroutes wordt veroorzaakt. Uit de rapportage van de beslisboom water bleek bijvoorbeeld de bijdrage van drainage aan de jaarlijkse piekconcentratie voor imidacloprid 40% te zijn voor een scheurende kleigrond, waar deze in de NMI-3 0% is. Het is onduidelijk of deze vereenvoudiging van de berekeningsmethode grote effecten heeft op de berekende trend.

Exposure Toxicity Ratio minder geschikt voor schatting echte toxiche druk

Zoals hierboven vermeld is de NMI-3 niet geschikt om de absolute waarde van het risico van en de impact op het waterleven te schatten. De nu gebruikte indicator - de Exposure Toxicity Ratio - schaalt de concentraties echter wel realistisch op de intrinsieke toxiciteit van de stoffen, door te delen door de normconcentratie. Verder gaat de ETR uit van concentratieadditie voor alle stoffen. Op de relatieve schaal (deze stof is erger dan die, en deze plek is erger belast dan die andere) is deze indicator voldoende.

Mochten de concentraties in de toekomst beter geschat kunnen worden en de blootstellingspaden beter bij elkaar opgeteld kunnen worden, dan lijkt de toxiche druk (msPAF) gebaseerd op de acute LC50 een betere schatter voor de impact op het waterleven. De daarbij behorende berekeningen moeten dan worden uitgevoerd volgens het gemengde model (optellen van concentraties voor stoffen met gelijke werkzaamheid en respons additie voor groepen van stoffen met een ongelijk werkzaamheid). Deze procedure wordt op dit moment door de beslisboom werkgroep multistress getoetst.

Emissiemodule voor grondgebonden teelten in kassen verouderd

De emissiemodule voor grondgebonden teelten in kassen gaat uit van berekeningen met het metamodel van PEARL voor open teelten, waarbij standaard 0.1% van de dosering bij de emissie wordt opgeteld. Dit getal is gebaseerd op expert judgement en leidt voor sterk sorberende stoffen tot een zware overschatting van de milieubelasting.

Aanbevelingen

Voor de evaluatie van het Nationaal Actieprogramma moeten vermoedelijk beheersmaatregelen worden doorgerekend. Om het model voor dit doel geschikt te maken adviseert de wbg om tijdig te beginnen met de nodige veranderingen:

- voer een gevoeligheidsanalyse uit, zodat inzichtelijk wordt welke variabelen van invloed zijn op de berekende indicatoren en welke maatregelen hierop ingrijpen. Een matrix, waarin verschillende combinaties van teeltvrije zone en drift reducerende techniek worden doorgerekend, zou bijvoorbeeld bijzonder behulpzaam zijn bij het interpreteren van de resultaten;
- pas de NMI zodanig aan, dat gerekend wordt met een watervolume dat gebaseerd is op een sloot naast een behandeld perceel (en dus niet met het watervolume van een plot). Op deze manier sluit de berekende concentratie in oppervlaktewater beter aan bij de realiteit en wordt berekening van de distance to target indicator alsmede het oppervlak waarop de norm wordt overschreden beter haalbaar. Bij de berekening van de distance to target indicator past wel de kanttekening dat de dosering in de praktijk nauwkeuriger beschikbaar dient te zijn - de CBS enquêtes bevatten deze informatie niet. De wbg adviseert daarom te laten onderzoeken in hoeverre de dosering in praktiksituaties kan worden geschat met aanvullende informatie en welke onzekerheid voortvloeit uit het gebruik van dergelijke informatie;
- onderzoek of de exposure toxicity ratio vervangen kan worden door een maat die de gevoeligheid van meerdere soorten integreert en ook mengseltoxiciteit beter kan integreren, zoals de msPAF;

- zorg voor een betere afstemming van de conceptuele basis van de deelmodellen. Schenk hierbij aandacht aan het tijdspercentiel en harmoniseer deze;
- pas het model zodanig aan dat de bijdragen van de verschillende emissieroutes gelijkwaardig in kaart kunnen worden gebracht;
- zorg voor een update van de module voor grondgebonden teelten;
- zet de wiskundige concepten van wijzigingen in de NMI op papier voordat met de softwareontwikkeling wordt begonnen en bespreek die met een (toekomstige) wbg.

Tenslotte

Wij bevelen verder aan dat de begeleidingscommissie vooraf zijn goedkeuring geeft aan de beleidsmatige aannames die ten grondslag liggen aan de berekening van de distance-to-target indicator en van het oppervlak waarop de oppervlaktewaternorm wordt overschreden. Bijvoorbeeld de spray drift in de akkerbouw is nu gebaseerd op 90 percentielen in de tijd. Het ligt niet zonder meer voor de hand om een oppervlak waarop de norm wordt overschreden, te baseren op gebeurtenissen die slechts eenmaal in de tien jaar gebeuren op een bepaalde locatie.

Wij bevelen tenslotte aan dat een toekomstige wetenschappelijke begeleidingsgroep niet alleen verantwoordelijk is voor de beoordeling van de wetenschappelijke concepten, maar ook voor de beoordeling van de kwaliteit van de invoer en van de met de NMI verkregen resultaten.

Appendix 9 Pesticide environmental risk indicators literature search conducted in 2009

The NMI 3 was developed within the framework of Research Theme BO-12.07-004, and with additional contributions from the Statutory Research Tasks Unit for Nature & the Environment (WOT Natuur & Milieu). With these additional financial contributions (project numbers WOT-04-007-037 and WOT-04-007-063), new risk indicators for groundwater, the soil ecosystem, and the terrestrial ecosystem were implemented in the NMI 3. The methodology of the risk indicators for these environmental compartments is described in the main report (Alterra Report 2250.1). Also within the framework of project WOT-04-007-037, a literature search was conducted in 2009. The aim of this literature search was to give an overview of risk indicators used at national scale in EU member states, and to compare these with the Dutch Environmental Indicator for pesticide risk, NMI 2. The results of this literature search conducted in 2009 are described in this appendix.

Pesticide environmental risk indicators

Dr. Patrick van Beelen, National Institute for Public Health and the Environment/RIVM

Abstract

In the Netherlands the Dutch Environmental Indicator NMI 2 for plant protection products is used to estimate the environmental impact of pesticides (1). This is calculated using pesticide sales, application methods, geographical information, pesticides properties, climate data, crop properties and other factors. Similar indicators exist in many other countries. In 2009, a literature search was performed on pesticide environmental risk indicators which are able to estimate the total risk of pesticides on a national scale. Two types of risk indicators are available: The first type is similar to the NMI 2 using ratios between the predicted environmental concentration and some quality standard. The second type simply adds scoring factors based on very dissimilar things like toxicity, bioaccumulation or occupational hazard. The second type uses arbitrary weighing factors which differ from author to author. The NMI 2 might be elaborated with extra modules on worker exposure and bioaccumulation plus consumer exposure. In the future the ratio based environmental risk indicators might be replaced with more advanced statistical methods based on exposure and sensitivity distributions.

1.1 Introduction.

Pesticide environmental risk indicators can be used to describe risk trends over the years. This helps governments to evaluate their crop protection policies. It is not sufficient to monitor the sales of a number of pesticides over the years. Typically there is a change in pesticide use over the years due to the admission of new pesticides and the termination of old pesticides. Generally the new pesticides have less environmental hazards compared to the old ones. The crops differ over the years because profitable crops become more popular while the area of other crops declines. Also the weather during the growing season has an impact on the pesticide use and also on the pesticide emission to surface water. Improvement of spraying techniques can reduce the impact of pesticides on surface water. The concentration of pesticides in surface water can decrease rapidly after spraying due to sorption to sediment, evaporation, degradation and dilution. The toxic

effect of a short but high dose of a pesticide can be considerable for sensitive organisms. The absence of sensitive organisms in surface water cannot always be attributed to pesticide use since many other factors like eutrophication, fishery, predators, parasites, diseases etc. can also play a role in an ecosystem. The large spatial and temporal variation of pesticide concentrations in surface water makes it difficult to assess the environmental risk of pesticides from measurements alone. It is difficult and costly to determine a huge number of pesticides and their degradation products in a frequent sampling scheme over large areas of surface water. Some pesticides are very difficult to determine at low concentrations. Bioassays can be used to determine whether surface water samples are toxic. Ecological observations give clues to the ecological status of surface water. The combination of environmental modeling, chemical analysis, bioassays and ecological observations are needed to assess the impact of pesticides on surface waters. The following chapters however will focus exclusively on the environmental modeling. The comparison between the Dutch Environmental Indicator (NMI 2) and other environmental risk indicators will yield possibilities to improve the models. Before a comparison between the NMI 2 and other models can be made it is necessary to introduce the NMI 2.

1.2 The Dutch Environmental Indicator/NMI version 2.

1.2.1 Input.

In the Netherlands the Dutch Environmental Indicator for plant protection products has been developed (1) by two Dutch institutes namely Alterra and RIVM. The NMI 2 consists of a software package which is described on the Internet (www.pesticidemodels.eu) (2). The NMI 2 uses pesticide sales and other input like:

- crop distribution during the survey years 1998, 2004
- pesticide interception by crops depending on growth stage
- distribution of greenhouses with soil or substrate cultivation
- long-term average monthly temperature and other climate data
- pesticide application methods and techniques
- drift to surface water data, leaching fractions, and point source emission factors
- pesticide fate and ecotoxicological quality standards

Geographical databases with local meteorological, physical and chemical soil conditions, boundary conditions for drainage flow and groundwater flow using a 250 m grid are used together with crop distribution maps using a grid of 1 km² over the Netherlands. Over 60 different crops are distinguished. The major ones are 10,000 km² grass, 2000 km² fodder maize, 1000 km² of winter wheat, sugar beets and potatoes. Different application techniques like field spraying, granules, fogging, dipping are accounted for in the NMI 2 model. The spray drift and the crop interception fractions were derived from elaborate experimental data (1).

1.2.2 Emissions

The NMI 2 model uses the above input to calculate emissions of pesticides to air, groundwater, and surface water. Volatilisation to air is calculated from the application spray, plants leaves and soil surface. The NMI 2 uses a metamodel of the PEARL model to calculate the leaching to groundwater. This PEARL model is validated by a number of experimental studies (3, 4). The amount of pesticide reaching surface water is calculated from spray drift and from drainage via the groundwater. The NMI 2 also calculates a number of points source emissions of pesticides from farm yards.

1.2.3 Soil

The amount of pesticide reaching the ground is calculated from the application rate and several loss fractions accounting for transport by air (1). The model assumes that the pesticides are homogeneously mixed through a layer of 5 cm of soil. Except for the cases when the pesticides are incorporated in soil. In that case a mixing layer of 20 cm is assumed (1). The degradation rate of the pesticide in soil is used to calculate a time weighed average concentration over 2 weeks. This yields the Predicted Environmental Concentration (PEC). For each application the PEC is divided by Predicted No Effect Concentration (PNEC) for soil organisms to calculate the number of Environmental Indicator Units (EIU) per grid cell. The PNEC of each pesticide is calculated from terrestrial toxicity tests for a number of different soil organisms using European guidelines (5). For the evaluation of the Dutch policy on sustainable crop protection, which contains operational targets for the reduction of environmental risk based on quality standards, the PEC is related to the Maximum Permissible Concentration in soil (MPC_{soil}) instead of the PNEC.

The total EIU per 1 km² grid cell resulting from all pesticide applications is a measure of the combined toxicity of the major pesticides.

1.2.4 Groundwater

For groundwater the calculated PEC is compared with the 0.1 µg pesticide/liter groundwater that is allowed by European legislation (7).

1.2.5 Surface water

The exposure of surface water is of course strongly dependent on the presence of surface water in each grid cell. For each grid cell the length of the ditches were measured and stored in the database. The NMI 2 assumes that the ditches are all 1 m wide, 0.3 m deep and have side slopes of 45°. This gives 210 liter surface water per meter of ditch (1). The nominal application rate of a pesticide is multiplied by a drift fraction to calculate the amount of pesticide reaching the ditch. Dissipation and volatilization rates are calculated for each pesticide to account for the removal of the pesticide from the water phase. Multiple pesticide applications are also accounted for. The PEC is calculated as a time weighed average concentration over 3 weeks. This PEC is divided by the PNEC to give the EIU for each application containing surface water. For the evaluation of the Dutch policy on sustainable crop protection, which contains operational targets for the reduction of environmental risk based on quality standards, the PEC is related to the Maximum Permissible Concentration in surface water (MPC_{sw}) instead of the PNEC.

1.2.6 Terrestrial ecosystems

In the NMI 2 the partridge has been chosen as standard species for the terrestrial ecosystem. The model is also useful for other birds and also for mammals when the food uptake data are available. For the moment only the impact of sprayed pesticides is accounted for. Seed dressings and other applications are not yet incorporated in the NMI 2. The Daily Chemical Intake DCI is calculated from the pesticide dose and the food uptake. The EIU for each terrestrial grid cell is calculated by dividing the DCI with the No Observed Effect Concentration (NOEC).

1.2.7 Adding up EIU values

Standard NMI 2 output files contain the total EIU resulting from all applications per 1 km² grid cell: 1) per crop, 2) per pesticide, and 3) all crops and pesticides. At regional or national scale level, the aggregated EIU per crop-pesticide combination is calculated. The EIU values are calculated from the predicted environmental concentration and the predicted no effect concentration using:

$$\text{EIU} = \text{PEC}/\text{PNEC}$$

While this formula is presented in European guidelines (8) it can be used to determine whether a specific pesticide concentration confirms to legislation. It is however not clear what happens at EIU values which are not equal to 1. An EIU value of 0.1 of one pesticide might be much more toxic than the same value for another pesticide. This depends on the sensitivity distribution of species for a certain pesticide. Pesticides with a broad species sensitivity distribution on one hand will be very toxic for some species but not toxic at all for other species. Pesticides with a narrow distribution on the other hand will be almost equally toxic for all species. The multi-substance potentially affected fraction of species is a better approach to summarize the toxicity of multiple pesticides (9). It is however not yet incorporated in the NMI 2 while it is already incorporated in the PERPEST model which can predict the effect of pesticides in a certain water body (10).

1.2.8 Applications

The NMI 2 is used for the interim evaluation of the Dutch policy on sustainable plant protection, showing a considerable reduction of the environmental risk of pesticides in the Netherlands between 1998 and 2005 (6). The results of the NMI 2 were compared with the results of different surface water monitoring programs. Large differences between measurements and model calculations are still present. Both the monitoring program and the NMI 2 must be improved. The NMI 2 module which calculates emissions from greenhouse horticulture needs to be improved. Banned pesticides are not incorporated in lack of usage data. The measurements need smart, coordinated monitoring schemes and lower detection limits (11).

1.3 Literature search

In order to compare the NMI 2 with other indicators a literature search was performed in the scientific database Scopus. A query for TITLE-ABS-KEY(pesticides “risk indicator”) yielded 31 results. The most cited one (12) reported about the CAPER project (Concerted Action on PEsticides Risk indicators). This project evaluated eight pesticide risk indicators developed in Europe. It was a cooperation of authors from 14 European countries. This publication was used as a starting point to find 12 related publications on pesticides risk indicators which did cite this one directly and indirectly. A relatively recent report of the FOOTPRINT project gave an up-to-date overview of the different functional tools for pesticide risk assessment and management (13). The FOOTPRINT project will give tools to make assessments of pesticide contamination in 2009 (14). At this stage European wide information on soils, climate types, crops and pesticide use is becoming available (14). Also the XIII symposium on pesticide chemistry in 2007 gave information about recent developments (<http://www.symposiumpesticide.org>). The elaborate proceedings of the conference were searched for papers on risk indicators. In the next paragraphs the information from literature is summarized.

Table 1 gives an overview of the indicators of environmental risk. Quite a few indicators were mentioned in the FOOTPRINT report (13) but were not accompanied by references. The table has a column called “Regional” (Reg.), which scores whether the index is suited as an indicator for regional or higher scale pesticide risks. The

higher scale might be a country, a catchment area of a river or even a continent. Many indicators are designed to determine the risk of pesticides at the farm level but not at a national scale. The lower rows in the table have a score in the regional column according to the FOOTPRINT report since no literature references are available. The other scores in column Reg. or Ratio are given by the author of this report after reading the literature references. The column Ratio makes a distinction between the indicators based on PEC/PNEC ratios (Exposure Toxicity Ratios/ETR) and the other indicators. Some of these other indicators are quite arbitrary and for instance do not predict concentrations in soil, groundwater or surface water. Typically these other indicators add up scores from very different endpoints like toxicity, persistence or leakage to groundwater. The FOOTPRINT indicator did not receive a score in the Ratio column because it is not finished yet. It is however likely to be very interesting when it is fully reported in the near future.

1.3.1 Indicators which add up PEC/PNEC ratios

The German SYNOPS indicator (15) is comparable with the NMI 2. Both models calculate an initial Predicted Environmental Concentration and a chronic PEC. Both relate the chronic PEC with a corresponding duration of a toxicity test which is used to calculate the PNEC. The SYNOPS indicator also uses Bioconcentration Factors for the risk evaluation of soil and surface water. This is not performed in the NMI 2 which will be a drawback when old-fashioned bioaccumulative pesticides like DDT are used. The bioconcentration factor in SYNOPS is not really well incorporated into the model since it was not reported in a recent paper on the application of SYNOPS in Mexico (16). In a recent comparison with eight other indicators, the SYNOPS indicator was selected as the best European indicator by American researchers (17). The NMI 2 was not included in this comparison.

The Belgian PRIBEL indicator (18) is an extension of the Poer indicator (19) which was only suitable for farm level risk assessments. The authorities in Belgium aimed at a 25% impact reduction of pesticides in 2010 compared with 2001. Therefore the PRIBEL was developed to calculate the impact of pesticides on a national scale. The indicator assesses both the risk to the environment and the human risk from occupational exposure. Only the latter risk was elaborated in a symposium paper (18) but the general principle can easily be applied for environmental risk evaluation. The NMI 2 does not contain a module to calculate the human risk from occupational exposure. On the local scale a risk index RI for pesticide operators was calculated in the PRIBEL indicator as the quotient of the internal exposure and the acceptable operate exposure level (both expressed in mg/kg body weight/workday). This risk index is multiplied by a so-called "frequency" F to calculate the impact. The frequency F is obtained by dividing the total used quantity Q (kilogram active substance) of a specific pesticide per crop in Belgium by the application rate (kilogram active substance/hectare) of that pesticide (18). The dimension of F is hectare. The total risk $RI \cdot F$ is comparable to the EIU of the NMI 2. Both are a risk factor summed up over an area for Belgium or the Netherlands. Independently from each other both the Belgium and the Dutch researchers came up with a rather similar approach.

The environmental yardstick is a simple indicator for the ecological impact of pesticides (20). It calculates environmental impact points which are very similar to the EIU values.

1.3.2 Arbitrary indicators

The Italian PRISW1 indicator (21) can be used as a site-specific tool for mapping the risk of pesticides in surface waters. The model uses an arbitrary score index of EC50/PEC ratios for algae, daphnia and fish to convert pesticide concentrations to a toxicity index. The weight factors for algae, daphnia and fish are 3, 4 and 5.5 respectively. The EC50/PEC ratios are converted into score values in an arbitrary way (21).

Table 1

The different pesticide environmental risk indicators.

27	PAF	Y		Netherlands		
28	PI	Y				
29	Rating system	Y				
30	REXTOX	Y				
31	SIRIS	Y		France		
32	SRI	Y		Sweden		
33	SyPEP	Y		Belgium	system for predicting the environmental impact of pesticides	
34	DIAPHYT	N				
35	EcoRR	N				
36	EPRIP	N				
37	I-phy	N				
38	PERI	N				
39	PESDECIDE	N				

This approach will be subjected to environmental validation (21). The arbitrary nature of the PRISW indicator makes it difficult to predict what kind of effects will happen at a certain value of the index. Other pesticide risk indicators are also used in Italy. The ARI indicator combines REXTOX (Ratio of EXposure to TOXicity), ADSCOR (ADditive SCORing) and SYSCOR (SYnergistic SCORing). These indicators content of both acute and chronic risk 43 aquatic species, algae, daphnia and fish (22). The authors indicate that they will use the HAIR tools

developed in an European framework program when these become available. The Norwegian NERI model also uses a score index which adds up things like toxicity for earthworms, leaching potential, persistence, bioaccumulation and formulation type (23). The same is true for the British EIQ index (24). Also for these models it is difficult to predict what kinds of effects will happen at a certain value of the index.

1.4 Conclusions

At the mid-term evaluation of the Dutch crop protection policy, which was conducted in 2006 (11), the NMI 2 is a state-of-the-art pesticide risk indicator which is able to produce national evaluations of changes in pesticide policy. It is part of a family of Exposure Toxicity Ratio based indicators which at this stage seemed to be superior of the more arbitrary indicators which add up scores from very different endpoints. The NMI 2 might be elaborated with a module on occupational exposure of pesticide operators and with a module on bioaccumulation and consumers risks. In the future adding up PEC/PNEC ratios will become old-fashioned because better ecotoxicological models will become available. These models will use statistical exposure and sensitivity distributions.

Alterra is part of the international expertise organisation Wageningen UR (University & Research centre). Our mission is 'To explore the potential of nature to improve the quality of life'. Within Wageningen UR, nine research institutes – both specialised and applied – have joined forces with Wageningen University and Van Hall Larenstein University of Applied Sciences to help answer the most important questions in the domain of healthy food and living environment. With approximately 40 locations (in the Netherlands, Brazil and China), 6,500 members of staff and 10,000 students, Wageningen UR is one of the leading organisations in its domain worldwide. The integral approach to problems and the cooperation between the exact sciences and the technological and social disciplines are at the heart of the Wageningen Approach.

Alterra is the research institute for our green living environment. We offer a combination of practical and scientific research in a multitude of disciplines related to the green world around us and the sustainable use of our living environment, such as flora and fauna, soil, water, the environment, geo-information and remote sensing, landscape and spatial planning, man and society.
