THE DIGESTIVE SYSTEM OF SOME SPECIES OF CHAITOPHORIDAE (HOMOPTERA: APHIDOIDEA)

INTRODUCTION

The digestive system of the Chaitophoridae, sensu BÖRNER, consists of a short foregut, a tubular or egg-shaped stomach, and a normal intestine but lacks a filterchamber (BÖRNER, 1952; BÖRNER and HEINZE, 1957; KUNKEL and KLOFT, 1977). These morphological features were illustrated by WITLACZIL (1882) in a drawing of the digestive system of *Chaitophorus populi* L. and by BÖRNER (1938) in that of *Periphyllus* sp., *Siphra* sp., and *Tranaphis* sp. (= *Chaitophorus* sp.).

In the present study the anatomy of the digestive system of a number of species of Chaitophoridae is investigated in more detail.

MATERIALS AND METHODS

Specimens of the species listed in Table 1, were fixed in DUBOSQ BRASIL's fluid, embedded in paraplast, and sectioned at 8 μ . Sections were stained in EHRLICH's haematoxylin-eosin or in 1% methylgreen aqueous solution (CALBERLA, 1887).

RESULTS

The most anterior part of the alimentary tract, the food canal in the maxillary stylets leads into the pharyngeal duct which in turn leads into the pharynx. This structure passes upwards through the head, over the tentorium and into the foregut which opens into the stomach via a valve. The stomach opens into the intestine which extends forwards and which after one additional loop or coil or neither (Fig. 2), runs posteriad to open into the rectum which ends at the anal opening (Fig. 1). The total length of the gut of *Chaitophorus populeti*, *C. populialbae*, *C. vitellinae*, *Periphyllus obscurus*, and *P. testudinaceus* is about twice that of the body (Fig. 2).

The foregut (oesophagus) runs posteriad between the two salivary glands, and dorsal to the nervous system, to end in the oesophageal valve. It consists of a thin tube made up of a single layer of squamous epithelial cells which secrete the chitinous intima.

The oesophageal valve is a short invagination of the foregut into the stomach. The inner surface is lined with squamous epithelium and the outer surface with cuboidal cells. The valve is covered with an intima.

TABLE I. List of the species of Chaitophoridae studied, their hostplant, and relevant locality data.

Aphid	Hostplant	Locality
<i>Atheroides serrulatus</i> HALIDAY	grass	Wageningen, 12.VII.1982
<i>Caricosipha paniculatae</i> BÖRNER	<i>Carex otrubae</i>	Opheusden, 22.IX.1982
<i>Chaitophorus capreae</i> (MOSLEY)	<i>Salix</i> sp.	Wageningen, 23.VI.1981
<i>Chaitophorus horii</i> subsp. <i>beuthani</i> (BÖRNER)	<i>Salix</i> sp.	Wageningen, 19.V.1979
<i>Chaitophorus leucomelas</i> KOCH	<i>Populus</i> sp.	Wageningen, 9.VI.1981
<i>Chaitophorus salijaponicus</i> subsp. <i>niger</i> MORDV.	<i>Salix</i> sp.	Wageningen, 2.VII.1981
<i>Chaitophorus populeti</i> (P.Z.)	<i>Populus alba</i>	Heemskerk, 18.VI.1981
<i>Chaitophorus populialbae</i> (BOYER de FONSC.)	<i>Populus alba</i>	Wageningen, 16.VI.1981
<i>Chaitophorus saliceti</i> (SCHRANK)	<i>Salix cinerea</i>	Winterswijk, 29.VIII.1981
<i>Chaitophorus truncatus</i> (HSMNN.)	<i>Salix</i> sp.	Wageningen, 29.VI.1981
<i>Chaitophorus vitellinae</i> (SCHRANK)	<i>Salix</i> sp.	Lienden, 14.VI.1981
<i>Laingia psammiae</i> THEOBALD	<i>Ammophila arenaria</i>	Cadzand-Bad, 25.VII.1982
<i>Periphyllus acericola</i> (WLK.)	<i>Acer pseudoplatanus</i>	Bennekom, 1.VIII.1980
<i>Periphyllus obscurus</i> MAMONTOWA	<i>Acer campestre</i>	Wageningen, 6.IX.1981
<i>Periphyllus testudinaceus</i> (FERNIE)	<i>Acer campestre</i>	Slijk-Ewijk, 22.V.1977
<i>Siphon elegans</i> del GUERCIO	grass	Wageningen, 10.VII.1981
<i>Siphon glyceriae</i> (KLTB.)	<i>Agrostis tenuis</i>	Bennekom, 24.VI.1981

The midgut is the longest part of the alimentary tract and consists of a stomach, first and second part of intestine, and descending intestine.

The stomach either starts in the mesothorax, metathorax, or first abdominal segment and joins the intestine in the first or second abdominal segment (Table 2). The stomach lies in the dorsal region of the aphid and has a tubular structure of which the anterior or middle region is somewhat dilated (Fig. 2; Table 3), depending on the species. The triangular cells of the stomach contain heterogeneous basophilic cytoplasm, small vacuoles, granules, and a spherical to oval nucleus. Their basal cell membranes have numerous invaginations and their free surfaces a striated border. These cells do not show any cytological manifestations of secretion (Fig. 3A), but in *Laingia psammiae*, *Siphon elegans*, and *S. glyceriae* the lumen of the stomach is filled with flocculent material (Fig. 3B). However, KUNKEL (1966) reports merocrine secretion by the stomach cells in *Chaitophorus (Eichochoaitophorus) versicolor* (Koch) (= *Chaitophorus leucomelas* KOCH).

The first part of the intestine consists of a small tube which runs from the stomach directly ventrad, then posteriad before reversing its direction (the abdominal loop) which may occur in the third, fourth, fifth, sixth, or seventh abdominal segment (Table 3). A similar structure is found in *Glyphina* and *Thelaxes* (PONSEN, 1982). In each aphid mentioned in Table 2 the first part of the intestine bends either to the right or to the left of the descending intestine. The abdominal loop is connected to the cauda by 'membranes'. The broader second part of the intestine starts at the abdominal loop and runs either directly anteriad to the thoracic loop, or before reaching the thoracic loop forms one loop or one

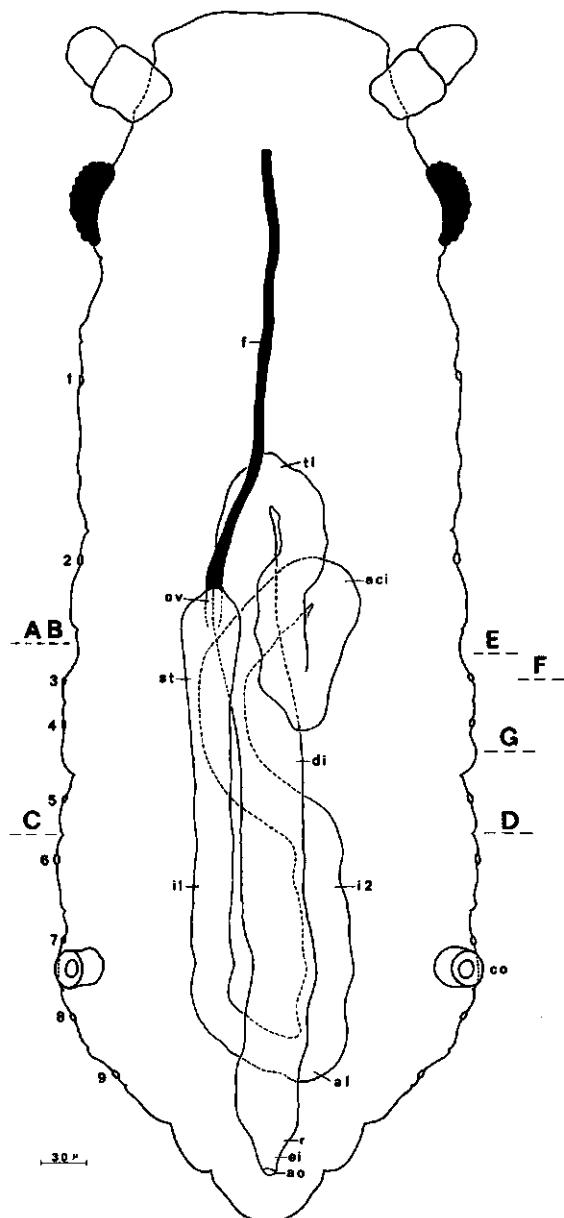

FIG. 1. Dorsal view of the digestive system of a larva of *Chaitophorus populeti* reconstructed from serial sections. The siphunculi (co) are situated on the fifth abdominal tergite. 1–2, meso- and metathoracic spiracles; 3–9, abdominal spiracles. aci, additional coil of intestine; al, abdominal loop; ai, additional loop of intestine; ao, anal opening; di, descending intestine; ei, epidermal invagination; f, foregut; i1, first part of intestine; i2, second part of intestine; ov, oesophageal valve; r, rectum; st, stomach; tl, thoracic loop. The letters A–G correspond with transverse sections given in Fig. 3.

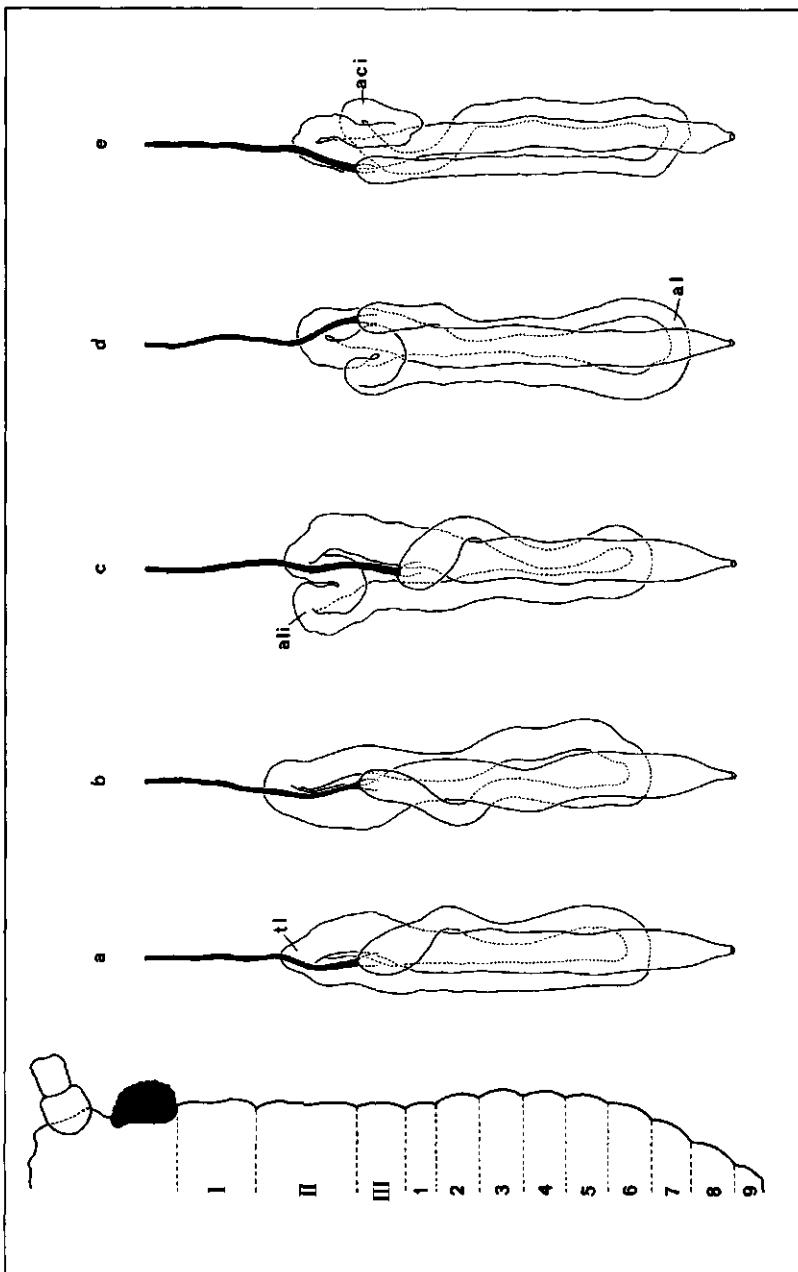

FIG. 2. Semi-schematic representation of the digestive system of *Periphyllus testudinaceus* (a), *Chaitophorus vitellinae* (b), *Periphyllus obscurus* (c), *Chaitophorus populihae* (d), and *C. populei* (e). I-III, thoracic segments; 1-9, abdominal segments. The letters a-e correspond with those in Table 3. For explanation of abbreviations see Fig. 1.

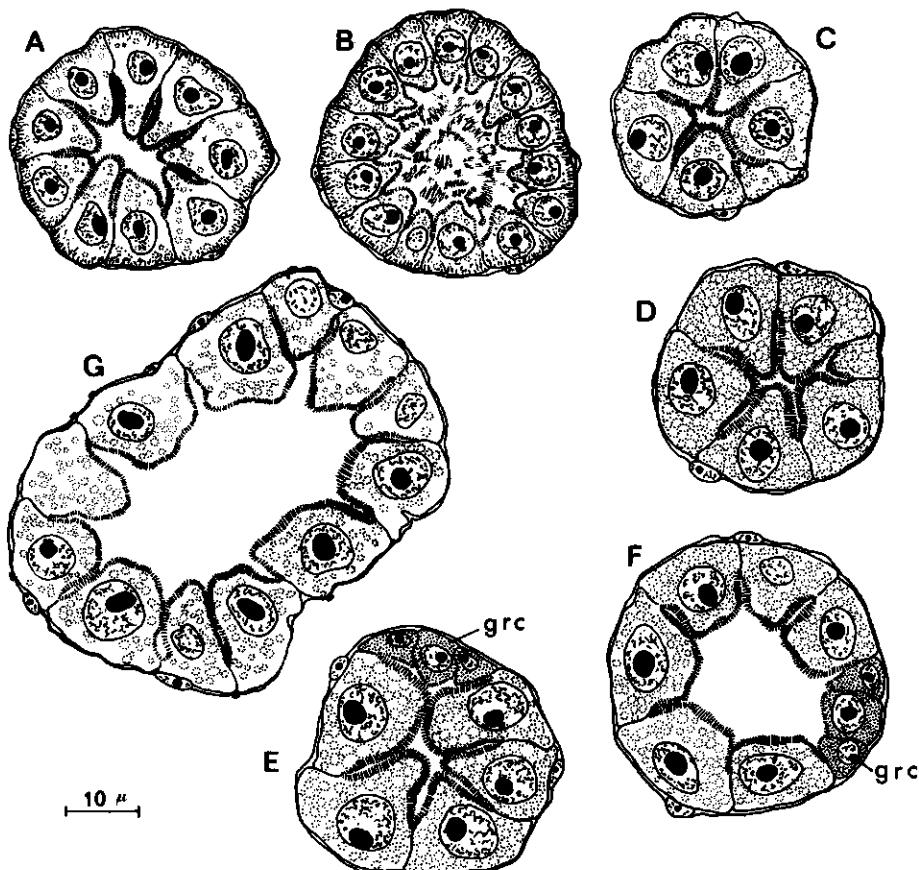

FIG. 3. Transverse sections of the stomach of *Chaitophorus leucomelas* (A) and *Laingia psammiae* (B), the first part of the intestine (C) and second part of the intestine of *Chaitophorus populeti* (D), the second part of the intestine showing granulated cells (grc) of *C. populeti* (E) and *Periphyllus testudinaceus* (F), and the descending intestine of *P. testudinaceus* (G). The position of the sections A–G are given in Fig. 1.

coil (Fig. 2; Table 3). The epithelial cells of the first part of the intestine contain few vacuoles and a somewhat spherical nucleus, whereas the cells of the second part of the intestine are strongly vacuolated and have ovoid nuclei (Fig. 3C and D). The free surfaces of these cells are striated and line a more or less stellate lumen.

In the second part of the intestine, particularly in the thoracic region and also in the additional loop or coil, there are groups of three small cells (Fig. 3E and F). The middle cell in each group has a large spherical nucleus, whereas the other two cells have relatively small nuclei. The cells contain granules, some vacuoles, and their free surfaces are presumably striated. In dissections of the aphids these groups of cells are seen as round white structures on an opaque intestine.

After the thoracic loop the second part of the intestine leads gradually into the descending intestine, which runs directly caudad and leads into the rectum. In dissections it is a transparent, sac-like structure with vigorous peristaltic movements. Histologically the descending intestine of all Chaitophoridae investigated (Table 2; Fig. 3G) is similar in structure to that of the species of Callaphididae that lack a filtersystem, *Glyphina*, *Thelaxes* (PONSEN, 1982), and the aphids listed in Table 4.

The rectum is made up of a single layer of small cuboidal cells and is connected to an epidermal invagination, the anal opening, which is both laterally and dorsally connected by muscles to the ninth abdominal segment.

DISCUSSION

Morphologically the digestive system of the chaitophorids investigated (Fig. 1 and 2) is similar to the description given by WITLACZIL (1882) for *Chaitophorus populi* L. and BÖRNER (1938) for *Siphra* sp. and *Tranaphis* sp. (= *Chaitophorus* sp.). But according to BÖRNER (1938) the intestine of *Periphyllus* sp. has a number of coils in the anterior region of the aphid. They both reported that these aphids have a hindgut, but did not describe it. However, in all the chaitophorids investigated the hindgut is of endodermal origin and an extension of the midgut, and therefore more correctly called a descending intestine.

Scattered groups of three small granulated cells occur in the wall of the second part of the intestine that otherwise consists of strongly vacuolated cells (Fig. 3E and F). These groups of cells occur mainly in the walls of the posterior portion (thoracic loop and additional loop or coil) of the second part of the intestine and are absent in the first part of the intestine. Granulated cells are found throughout the midgut of many insects and have been called gut endocrine cells (ENDO and NISHIITSUTSUNI-UWO, 1981). They are singly intercalated among the epithelial cells or the regenerative cells of the midgut. The regenerative cells may be scattered singly beneath the epithelial cells or grouped into clusters (nidi) there, or variously arranged in crypt-like outpocketings of the midgut (RICHARDS and DAVIES, 1957). These granulated cells also occur in the posterior portion of the ascending intestine of the Callaphididae with and without a filter-system, in the posterior portion of the intestine of *Phloeomyzus passerinii* (SIGMORET), and in the posterior portion of the second part of the intestine of *Myzus persicae* (SULZ.), *Cryptomyzus ribis* (L.), *Eulachnus*, *Glyphina*, *Thelaxes*, as well as in the aphids listed in Table 4.

SUMMARY

The digestive system of the Chaitophoridae has a short foregut which opens into the stomach via a valve (Fig. 1). The stomach has a tubular structure and leads into the first part of the intestine which runs from the stomach directly ventrad and then posteriad to end in the abdominal loop. From there a broader

intestine, the second part, runs either directly anteriad to the thoracic loop, or before the thoracic loop forms one additional loop or coil (Fig. 2). The descending intestine runs from the thoracic loop directly caudad to open into the rectum which ends at the anal opening.

SAMENVATTING

Het spijsverteringskanaal van de Chaitophoridae heeft een korte slokdarm die in de maag uitmondt via een oesophageale klep (Fig. 1). De maag heeft een buisvormige structuur en gaat over in het eerste gedeelte van de darm dat van de maag direct ventraalwaarts loopt en vervolgens caudaalwaarts om in de abdominale lis te eindigen. Vandaar loopt een wijder darmdeel of direct voorwaarts tot de thoracale lis, of het vormt voor de thoracale lis nog een lis (Fig. 2). De neerdalende darm zet zich vanaf de thoracale lis caudaalwaarts voort in het rectum dat via de epidermale invaginatie in de anale opening uitmondt.

ACKNOWLEDGEMENTS

I wish to express my thanks to DR. D. HILLE RIS LAMBERS (Edseweg 139, Bennekom), to ING. A. VAN HARTEN (Praia, Cabo Verde), DR. F. A. ILHARCO (Estação Agronomica Nacional, Oeiras, Portugal), and to DR. I. M. MILLAR (Pretoria, South Africa) for collecting and identifying of the aphids.

Thanks are also due to MR. A. J. WIT (Plant Protection Service, Wageningen) and DR. P. GRUPMA (Dorschkamp Research Institute for Forestry and Landscape Planning, Wageningen) for collecting the Adelgidae.

Corrections of the English text by Professor DR. A. F. G. DIXON (University of East Anglia, Norwich, England) are much appreciated.
