Modifications to the land surface scheme: HTESSEL

1. Discretisation from 4 to 8 soil layers,
2. Variable soil depth,
3. Groundwater effect included,
4. Root water uptake reduction function changed

Does the land surface model perform better?

- Special interest: spatial distribution of the latent heat fluxes
-
-
-
-

Does the land surface model perform better?

- Special interest: spatial distribution of the latent heat fluxes
- Comparison of weekly latent heat flux to satellite data (MODIS), using the SEBAL routine. Spatial resolution 1km.

Grid and test region

Sources of variability

- Meteorology: Rainfall and incoming radiation
- Variable soil characteristics (orography, vegetation, soil texture, etc)

RACMO and SEBAL daily net radiation

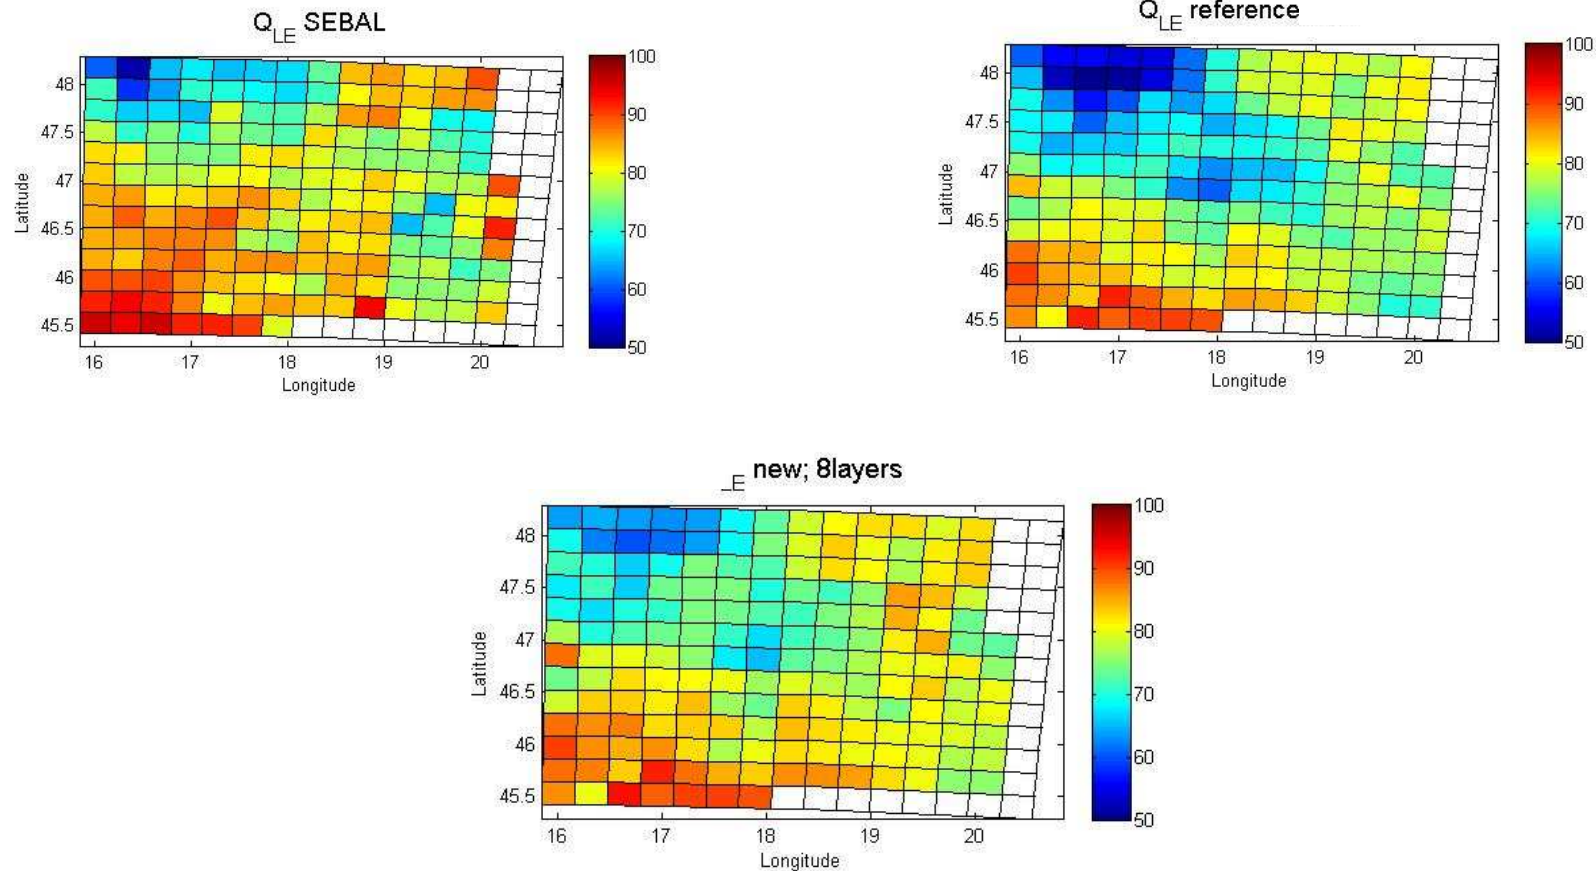

Cases

	Reference model	8 layers	8 layers, groundwater	8 layers, soil depth classes	8 layers, root function	8 layers, all
Soil layers	4	8	8	8	8	8
Root function changed	-	-	-	-	yes	Yes
Ground-water effect	-	-	Yes	-	-	Yes
Variable soil depth	-	-	-	Yes	-	Yes

Results: daily latent heat flux SEBAL and HTESSEL (W/m²)

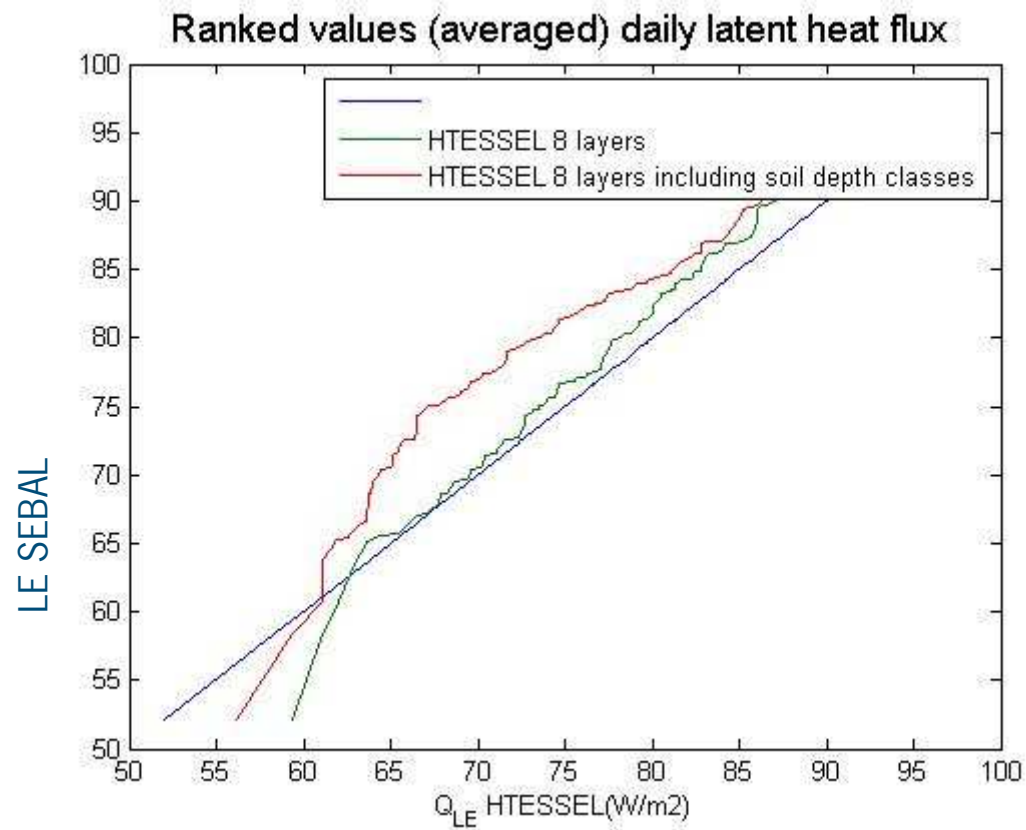

Scatter LE

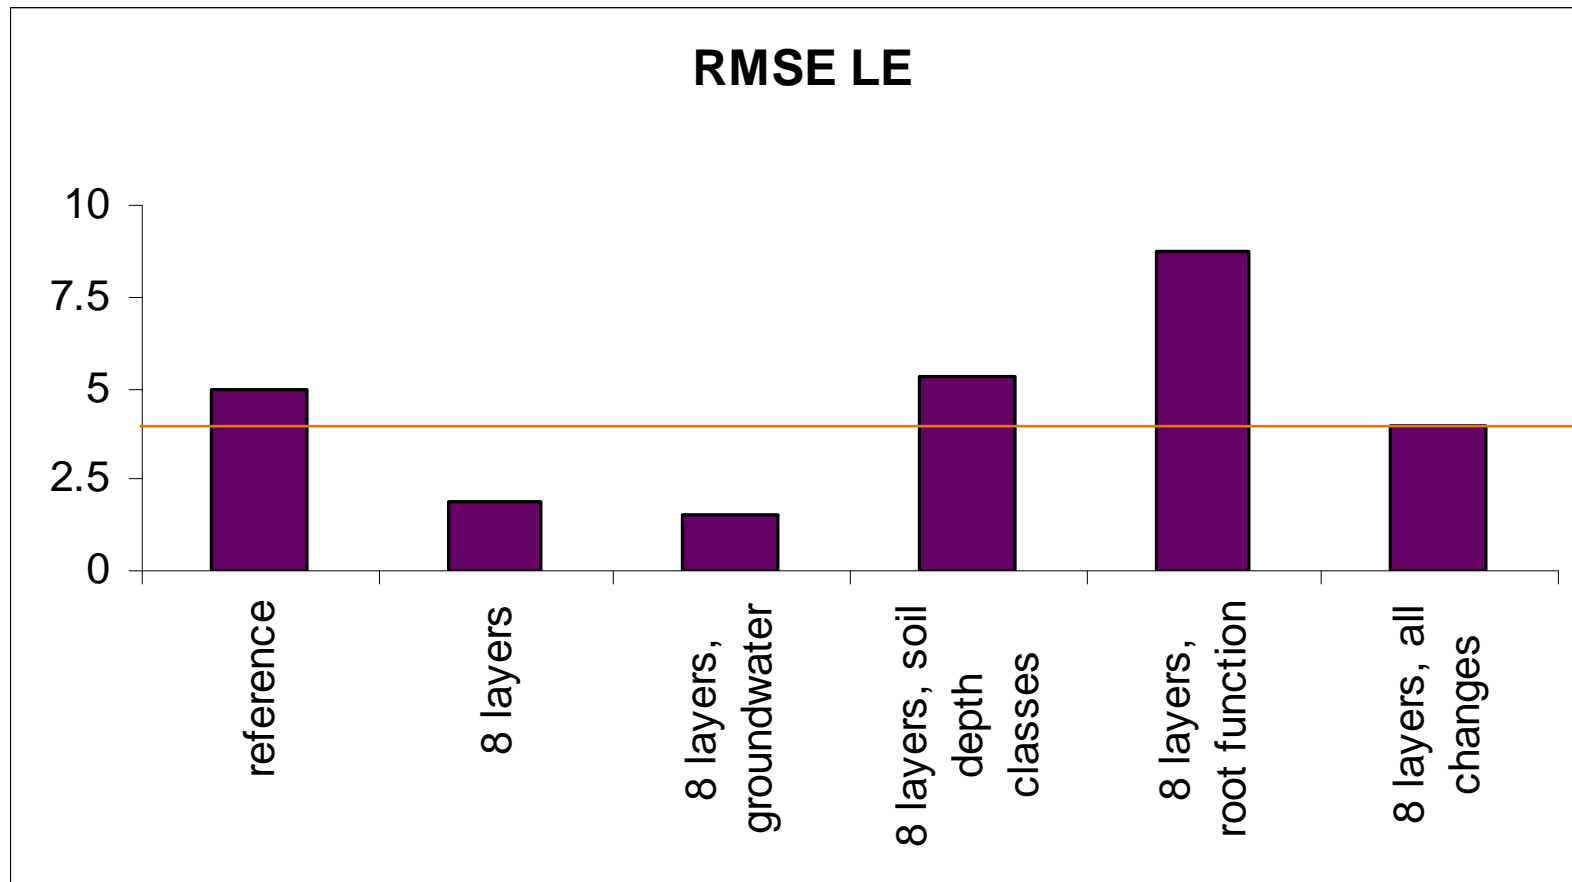

RMSE of ranked latent heat fluxes

Conclusions and future work

- RS data that cover a larger area are useful to test the performance of Land Surface Schemes
- Some of the modifications lead to a better performance of the scheme on a seasonal basis
- longer time series are needed
- Spatial correlation of the data should be considered, e.g. by variograms
- In addition to seasonal behavior also the monthly behavior should be considered
