**Abstract** STOWA developed the conceptual framework of the Ecological Key Factors for the ecological assessment of water quality issues. The key factors describe preconditions for good water quality. The key factors help to structure the available information of water quality and make it possible to pinpoint dominant processes in water system functioning. Understanding of the water quality functioning enables identification of effective restoration measures. Toxicity has been identified as one of the Ecological Key Factors. As part of water quality assessment with EKFs an evaluation should be made to assess whether the water system complies with the key factor toxicity. In a serie of five reports the methodology to assess whether the water quality complies with the ecological key factor toxicity has been described. The methodology gives insight in the effect of chemical compounds on the biology. This report is part 5 and is a background document on effect-based trigger values (EBT's) for the assessment of the ecological risks of (a combination of) compounds. The EBT's are used in the SIMONI model which can be applied to assess the chemical waterquality.

## SUMMARY

---

STOWA developed the conceptual framework of the Ecological Key Factors for the ecological assessment of water quality issues. The key factors describe preconditions for good water quality. The key factors help to structure the available information of water quality and make it possible to pinpoint dominant processes in water system functioning. Understanding of the water quality functioning enables identification of effective restoration measures. Toxicity has been identified as one of the Ecological Key Factors.

There are key factors for stagnant and streaming waterbodies. The Ecological Key Factor toxicity is applicable for both types.

In a serie of five reports the Ecological Key Factor toxicity is elaborated. The serie contains a main report and 4 attachments.

This report is part 5 and is a background document on effect-based trigger values for the assessment of the ecological risks of (a combination of) chemicals. The concept is part of the toxicology track described in part 1. Part 4 describes the procedures for monitoring.

Aquatic life is subjected to stress due to the release of thousands of chemicals in the water, but it remains hard to determine the ecological actual risks. A paradigm shift in the field of water quality assessment from a single-chemical approach to an effect-based approach would overcome the limitations connected with the current monitoring strategies. Chemical analyses can be conducted only on a limited set of known chemicals and it is virtually impossible to assess mixture toxicity of such complex mixtures. Bioanalytical tools, in combination with chemical analyses, can be a valid alternative to classic monitoring programs. Such an integrated approach would provide information regarding the overall impact of co-exposure to multiple chemicals (known and unknown) on different levels of biological organization.

This study aimed to design environmental effect-based trigger values (EBT) for a selection of bioassays. The aim of these EBTs is that they should provide initial hazard identification of organic micropollutants for the aquatic organisms. The EBTs will be included in a model called "SIMONI" (Smart Integrated MONItoring) that can be used to discriminate between 'low risk' sites, where no further analyses are needed, and 'potential risk' sites, where an additional risk assessment has to be conducted. The goal is to reduce monitoring costs, and meanwhile generate a more complete analysis of the chemical water quality by using a battery of bioassays covering the most relevant modes of toxicant action.

A three-step approach was used to design effect-based trigger values (EBT). A selection of compounds was made that have a known response in the bioassay, with relative effect potencies (REPs) close to the reference compound for that assay. The first step was a literature search for toxicity data on these selected compounds, and conversion to their TEQ values (toxic equivalents of the respective reference compounds). Lowest TEQs of all toxic effects found (divided by an assessment factor) will be used as 'save TEQ'. The second step was a species sensitivity distribution of all TEQ values in order to estimate the TEQ level that may cause an adverse effect to 5% of the species (HC5 TEQ). The HC5 TEQ should preferably be higher than or equal to the proposed low-risk effect-based trigger value (EBT). The final step was a benchmark with Waternet field data. The average bioassay responses at eight ecologically clean sites were considered as 'clean TEQ'. A realistic EBT was derived that should be higher than the average effect observed at eight reference sites with a good ecological status. In order to get a good discrimination between sites, the EBT should be exceeded only at a limited number of seriously polluted sites. Therefore, further validation studies will be needed to optimize the proposed trigger values in the near future.

Effect-based trigger values were derived for:

- estrogenic activity (Era CALUX): 0.5 ng EEQ/L;
- anti-androgenic activity (anti-AR CALUX): 25 µg F1EQ/L;
- glucocorticoid activity (GR CALUX): 100 ng DEQ/L;
- dioxin-like activity (DR CALUX): 50 pg TEQ/L;
- PPAR $\gamma$  receptor activity (PPAR $\gamma$  CALUX): 10 ng REQ/L;
- toxic PAHs activity (PAH CALUX): 150 ng BEQ/L;
- oxidative stress (Nrf2 CALUX): 10 µg CEQ/L;
- pregnane X receptor activity (PRX CALUX): 3 µg N1EQ/L;
- five classes of antibiotics activity (RIKILT WaterSCAN):
  - aminoglycosides activity: 500 ng N2EQ/L;
  - macrolides &  $\beta$  lactams activity: 50 ng PEQ/L;
  - sulphonamides activity: 100 ng SEQ/L;
  - tetracyclines activity: 250 ng OEQ/L;
  - quinolones activity: 100 ng F2EQ/L.

It is essential to propose better monitoring strategies in order to preserve the quality of freshwater environment. The introduction of bioassays in monitoring programs can lead to a more sustainable water quality assessment. This study may provide a reference for further measures and implementation of risk assessment of micropollutants in the water cycle.

# 1 INTRODUCTION

## 1.1. ECOLOGICAL KEY FACTORS

STOWA designed the conceptual framework of the Ecological Key Factors for the ecological assessment of water quality issues. The key factors describe preconditions for good water quality. The key factors help to structure the available information of water quality and make it possible to pinpoint dominant processes in water system functioning. Understanding of the water quality functioning enables identification of effective restoration measures. Toxicity has been identified as one of the Ecological Key Factors.

There are key factors for stagnant and streaming waterbodies. The Ecological Key Factor toxicity is applicable for both types.

In a serie of five reports the Ecological Key Factor toxicity is elaborated. The serie contains a main report and 4 attachments.

This report is part 5 and is a background document on effect-based trigger values for the assessment of the ecological risks of (a combination of) chemicals. The concept is part of the toxicology track described in part 1. Part 4 describes the procedures for monitoring.

## 1.2. EFFECTS OF CHEMICALS

Since the beginning of the industrialized era a constantly increasing number of anthropogenic chemicals have been released in the environment. The thousands of substances that reach the water cycle such as pharmaceuticals, pesticides, reproductive hormones, steroids, detergents, disinfectants, insect repellants and fire retardants (Erickson, 2002), may cause deterioration of the water quality and pose a threat to the aquatic ecosystems. In 2000, the European Parliament approved the Water Framework Directive (WFD, 2000/60/EC), in order to develop good monitoring programs and to classify the water bodies based on their chemical and ecological quality. The WFD represents a milestone in the field of water monitoring and management, but it is far from conclusive (Dworak et al., 2005). According to the directive, chemical quality of the water should be investigated through chemical analysis of selected priority compounds, whose concentrations should not exceed established Environmental Quality Standards or EQSs (Environmental Quality Standards Directive, 2008/105/EC). However, this single-chemical approach has been proven insufficient and can lead to an underestimation of the potential toxic hazard caused by thousands of compounds present in the water, since “as any analytical chemist knows, what you see depends on what you look for” (Lynn Roberts, Johns Hopkins University). Additionally, new chemicals are continuously developed to replace the current ones, and, as a consequence, the list of priority substances should be constantly updated. Moreover, chemicals that are present under detection limits can still cause significant mixture toxicity or create toxic metabolites and secondary products. Several authors (Altenburger et al., 2015; Escher and Leusch, 2012) highlight the need to develop new monitoring methods that will allow a more realistic overview of the risk connected with the presence of chemicals in the water phase.

A paradigm shift in the field of water quality assessment from a single-chemical approach to an effect-based approach would overcome the present limitations (Poulsen et al., 2011; Maas et al., 2004). As previously stated, only a small fraction of the compounds that could be present in the water are monitored with current programs. The introduction of effect-based techniques will lead to a more holistic and qualitative environmental risk assessment. As a matter of fact, this shift will allow us to detect toxicity of mixtures of (un)known bioavailable chemicals and to better link the cause (presence of chemicals) to the effect (toxicity for the aquatic communities). The first step of a risk assessment is a hazard identification to establish if a certain situation is of concern or not. The combination of bioassays with chemical analysis in water assessment appears to be a more suitable tool than only chemical analysis, which was demonstrated in several studies investigating the reliability of an effect-based methodology. Among others, Chapman et al. (2011) investigated water

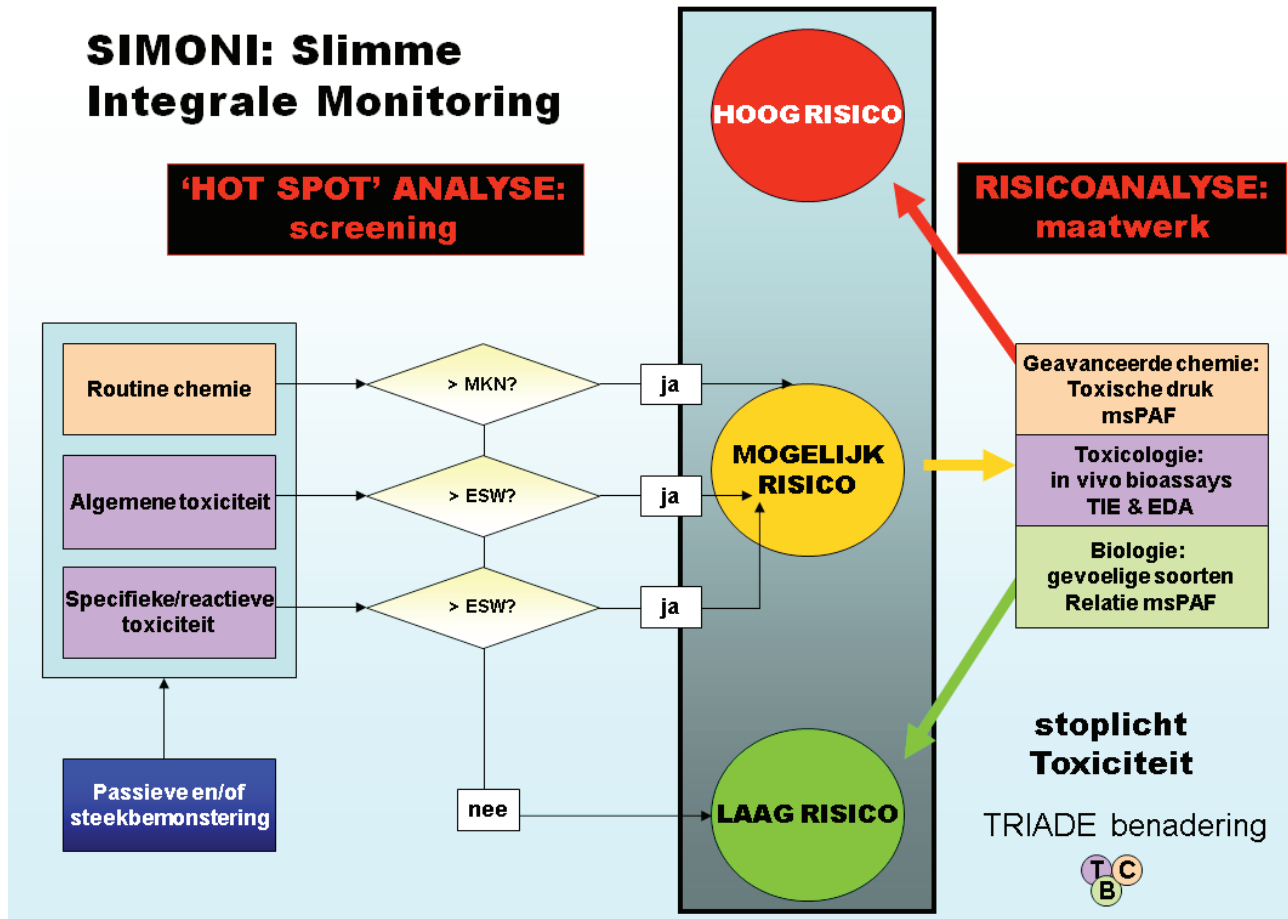

samples from nine water reclamation plants in Australia with a combination of chemical analysis and bioassays in order to characterize human and environmental risks. One of the main conclusion of this investigation was that bioassays and chemical analysis were complementary and in agreement. Additionally, bioassays were able to provide a more complete analysis of the water quality, since they detected activity at concentrations below the detection limit of chemical analyses. Maas and co-workers (2004) showed that bioassays are sensitive enough to evaluate the effects of all WFD priority pollutants, in particular PAHs, herbicides and insecticides.

Effect-based tools or bioassays are techniques that investigate the toxicity of samples, using biological systems. They can be classified in two categories based on the level of organization of the biological system: *in vivo* bioassays (conducted on organisms, population, or ecosystem level) and *in vitro* bioassays (conducted on isolated cells or tissues). The biggest limitation of the effect-based techniques is their inability to determine the identity of the compounds causing the observed toxic effects. Certain *in vitro* bioassays, however, allow the identification of groups of chemicals with a similar mode of toxicant action (MOA). Generally, *in vivo* bioassays assess non-specific toxicity while *in vitro* bioassays will measure specific or reactive toxicity. Several types of *in vitro* bioassays are available to detect a variety of toxic activities, such as estrogenic, androgenic, dioxin-like effects, genotoxicity and neurotoxicity (Escher and Leusch, 2012). A battery test is defined as a selection of bioassays targeting different toxic endpoints. The endpoint selection is based on the protection goal or the chemical activity that need to be targeted. A battery test selected for water quality assessment should cover all relevant MOAs, since the goal is to get a wide comprehensive picture of the toxic potency of the available micropollutants. Since *in vitro* bioassays are able to detect specific toxic activity of groups of chemicals, a broad selection of toxic endpoints will gain a more complete picture of chemical risks, including the effects of unexpected or unknown toxic substances (Escher and Leusch, 2012).

Several countries are already using bioassays to monitor the microchemical water quality (see de Zwart, 1995 and Wernersson et al., 2014 for an overview). Battery tests have also been used for water quality assessment, e.g., to investigate the efficiency of sewage treatment plants and the chemical quality of drinking water (Kienle et al., 2011; Macova et al., 2010; Pablos et al., 2009; Macova et al., 2011; Zęgura et al., 2009). In the Netherlands, bioassays have been applied for many years in surveillance monitoring of the Meuse, Scheldt and Rhine river basin. The use of bioassays, however, is restricted to research programs since there are no official guidelines to incorporate effect-based tools in regulatory monitoring programs. One of the main reasons for this is the lack of tools for a clear interpretation of bioassay results, such as effect-based triggers values (ETVs). The definition of EBTs will help water managers to define the bioassay responses that indicate that levels of micropollutants can be considered a “low risk” or a “potential risk” for the ecosystem. Several international projects like DEMAU (<http://demeau-fp7.eu>) and SOLUTIONS (<http://www.solutions-project.eu>), investigate and promote implementation of effect-based tools in current regulations for water quality assessment. In 2010, Waternet started a project called “Smart monitoring”. The main goal of this project is to combine traditional chemical analysis with effect-based tools in a tiered screening approach, in order to obtain a more efficient and cost-effective environmental risk assessment (Van der Oost et al., in prep). Bioassays will represent a powerful screening tool that will allow the classification of sites by a model called “SIMONI” (Smart Integrated Monitoring toxicity traffic light, Figure 1). According to the model, sites will be classified as low risk (green), potential risk (orange) and high risk (red), based on the responses of a battery of selected bioassays and target chemical analyses. Only when a potential risk is indicated an investigation with chemical analysis will be needed, in order to identify the chemicals causing the observed toxic effects.

**FIGURE 1**

Schematic representation of the SIMONI model (Van der Oost, in preparation a). Sites will be classified as low risk (green) or potential risk (orange) based on the responses of a bioassay battery. Advanced chemical analyses will only be needed at potential risk, to identify if the chemicals causing the toxic effects are a high ecological risk (red).

### 1.3. IN VITRO BIOASSAY BATTERY

The present study focusses on EBT for *in vitro* bioassays for specific and reactive effects, and bioassays for the determination of antibiotics activities. As stated above, *in vitro* bioassays are able to detect specific activities caused by unknown mixtures of compounds with the same MOAs (Sonneveld et al., 2005). The specific activity is expressed in toxic equivalents (TEQ), i.e., the amount of a reference compound (see Table 1) that would cause the same effect as all compounds of the unknown mixture the bioassay is exposed to. CALUX (Chemical Activated LUciferase gene eXpression) techniques are *in vitro* bioassays performed with modified cell lines that contain luciferase reporter genes and specific receptor sites. The binding of chemicals to a specific receptor will induce luciferase gene expression. After addition of the luciferine substrate, the intensity of the luciferase induction can be measured as an increased luminescence, which is a measure of the activity of all micropollutants with this specific MOA. Detection of antibiotics activities was performed with the Water SCAN bioassay, developed by RIKILT (Netherlands). This bioassay uses agar plates inoculated with five species of microorganisms that are sensitive to different classes of antibiotics with the same MOAs. After exposure to a sample, the growth inhibition of the microorganisms is measured as a clear area in the agar. The surface area of the clear spot, which is proportional to the total activity of specific antibiotics in the sample, was used to quantify the response. Different versions and improvements of the bioassay have been suggested and detailed information can be found in Pikkemaat et al. (2008).

#### ER CALUX

Estrogen receptors (ER) are a group of proteins found inside cells that are activated by the hormone estrogen (17 $\beta$ -estradiol). Once activated by estrogen, the ER is able to translocate into the nucleus and bind to DNA to regulate the activity of different genes (i.e. it is a DNA-binding transcription factor). Estrogen is the primary female sex hormone that is responsible for the development and regulation of the female reproductive system and secondary sex characteristics. Estrogen may also refer to any substance, natural or synthetic that mimics the effects of the natural hormone.

#### Anti-AR CALUX

The androgen receptor (AR) is a nuclear receptor that is activated by binding the androgenic hormones, testosterone or dihydrotestosterone in the cytoplasm and then translocating into the nucleus. The androgen receptor is most closely related to the progesterone receptor, and progestins in higher dosages can block the androgen receptor. The main function of the androgen receptor is as a DNA-binding transcription factor that regulates gene expression. Androgen regulated genes are critical for the development and maintenance of the male sexual phenotype.

#### DR CALUX

Dioxin Responsive bioassays, such as DR CALUX, are used to detect dioxins and dioxin-like compounds. It is based on the mechanisms of the arylhydrocarbon receptor (AhR) pathway (Murk et al., 1996). Chronic activation of the AhR-pathway by these compounds has been shown to cause cancer in the predominantly the liver and can cause developmental defects in vertebrates. DR CALUX is also used to screen food for dioxins and dioxin-like compounds in order to guarantee food safety. Dioxins are considered to be the most toxic man-made chemicals.

#### GR CALUX

The glucocorticoid receptor (GR) is the receptor to which cortisol and other glucocorticoids bind. The primary mechanism of GR action is the regulation of gene transcription. After the receptor is bound to glucocorticoids, the receptor-glucocorticoid complex can take either of two paths (Rhen and Cidlowski, 2005). The activated GR complex up-regulates the expression of anti-inflammatory proteins in the nucleus or represses the expression of pro-inflammatory proteins in the cytosol (preventing the translocation of other transcription factors from the cytosol into the nucleus).

#### NRF2 CALUX

Oxidative stress reflects the imbalance between the manifestation of reactive oxygen species and the biological ability to detoxify the reactive intermediates or to repair the resulting damage (Sies, 1985). Disturbances in the normal redox state

of cells can cause toxic effects through the production of peroxides and free radicals that damage all components of the cell, including proteins, lipids, and DNA. Base damage is mostly indirect and caused by reactive oxygen species (ROS) generated, e.g. superoxide radical, hydroxyl radical and hydrogen peroxide. The detection of oxidative stress with the *in vitro* Nrf2 CALUX ('Nuclear-factor-E2-related factor') is based on the activation of the Nrf2 pathway, which regulates cytoprotective enzymes in response to oxidants and electrophilic compounds through binding to the antioxidant response element (ARE) (Nguyen et al., 2009).

### PAH CALUX

Polycyclic aromatic hydrocarbons (PAHs) are one of the most widespread organic pollutants. The toxicity of PAHs is structure-dependent. Isomers (PAHs with the same formula and number of rings) can vary from being nontoxic to extremely toxic. One PAH compound, benzo[a]pyrene (BaP), is notable for being the first chemical carcinogen to be discovered. Certain PAHs are well known for their carcinogenic, mutagenic, and teratogenic properties. The PAH CALUX is designed for the detection of the activity of the most toxic PAHs, like BaP.

### PPAR $\gamma$ CALUX

The peroxisome proliferator-activated receptor gamma (PPAR $\gamma$ ) regulates fatty acid storage and glucose metabolism. The genes activated by PPAR $\gamma$  stimulate lipid uptake and adipogenesis by fat cells. PPAR $\gamma$  knockout mice fail to generate adipose tissue when fed a high-fat diet (Jones et al., 2005). Many naturally occurring agents directly bind with and activate PPAR $\gamma$ .

### PXR CALUX

PXR is a nuclear receptor whose primary function is to sense the presence of foreign toxic substances and in response up regulate the expression of proteins involved in the detoxification and clearance of these substances from the body (Kliewer et al., 2002). Receptors such as PXR recognize such xenobiotics and to control the expression of a large series of phase I, phase II, and phase III metabolizing enzymes and transporters. The encoded protein is a transcriptional regulator of the cytochrome P450 gene CYP3A4, binding to the response element of the CYP3A4 promoter as a heterodimer with the retinoic acid receptor (RAR). PXR is activated by a range of compounds that induce CYP3A4, including dexamethasone and rifampicin (Bertilsson et al., 1998).

## ANTIBIOTICS ACTIVITIES

### *Aminoglycosides*

Aminoglycosides bind irreversibly to different subunits of bacterial ribosomes and therefore interfere with protein synthesis (Brain et al., 2004). Streptomycin is one of the most commonly used aminoglycosides and, apart from binding to the 30S ribosomal subunit of bacteria, slows down the already initiated protein synthesis and produces misreading of mRNA (Van der Grinten et al., 2010).

### *Macrolides & $\beta$ -lactams*

Within the macrolides and  $\beta$ -lactams antibiotics, an important number of compounds have been tested on different organisms. Macrolides bind to the bacterial 50S subunit of the ribosome, inhibiting translocation of tRNA during translation (Van der Grinten et al., 2010).  $\beta$ -Lactams are another group of compounds, which often appear classified together with macrolides. They inhibit the synthesis of cell wall in bacteria by targeting the transpeptidase enzymes of these organisms (Wilke et al., 2005). Additionally, other compounds such as carbacephems (for example, cephalexin), pose a similar mode of action as  $\beta$ -lactams, inhibiting the synthesis of bacterial cell walls (Brain et al., 2004).

### *Sulfonamides*

Sulfonamides are synthetic compounds which act as folate antagonists, avoiding the production of coenzyme dihydrofolic acid by blocking the conversion of paminobenzoic acid in microorganisms (Brain et al., 2004). They pose a broad

spectrum of action against bacteria and coccidian and their presence in the environment is mainly due to the excretion of active forms and the transformation of their inactive metabolites back into the active form by bacteria, which explains their persistency and resistance in the environment (De Liguoro et al., 2009). Diaminopyrimidines are a group of antibiotic commonly presented together with sulfonamides because of their synergistic effect. The most common diaminopyrimidine is trimethoprim, which inhibits the enzyme dihydrofolate reductase by reversible binding, therefore interfering with the synthesis of folate (Van der Grinten et al., 2010).

### Tetracyclines

Tetracyclines bind irreversibly to the 30S ribosomal subunit, inhibiting the protein synthesis by blocking the binding of aminoacyl transfer to DNA (Brain et al., 2004). This group of antibiotic is most commonly used in veterinary applications. Oxytetracycline, one of the most commonly used tetracyclines, inhibits the protein synthesis by avoiding the interaction between aminoacyl-tRNA and the bacterial ribosome (Kołodziejska et al., 2013; Van der Grinten et al., 2010). Florphenicol and derivatives from thiamphenicol act on protein synthesis of Gram-negative and Gram-positive bacteria by inhibiting transpeptidation (Christensen et al., 2006; Kołodziejska et al., 2013).

### Quinolones

Quinolones are DNA gyrase and topoisomerase IV inhibitors, which present higher affinities for the bacterial enzyme than for the vertebrates' enzyme (Brain et al., 2004; Carlsson et al., 2009). These antibiotics have evolved from the first generation of quinolones, such as oxolinic acid, to the second and third generation, the fluoroquinolones. In these last ones, a fluorine atom was added to the structure, which improved the efficiency of these compounds (Robinson et al., 2005). One of the most commonly used quinolones is enrofloxacin, from which 11% is estimated to be transformed into its metabolite, ciprofloxacin (Rico et al., 2014a). Therefore, these compounds are sometimes estimated or tested for toxicity together.

## 1.4 AIM OF THE STUDY

As part of the 'Smart monitoring' (Waternet) and 'Ecological Key Factor Toxicity' (STOWA) projects, the present study aims to derive "low risk" effect-based trigger values (EBTs) for eight bioassays, targeting estrogenic activity, anti-androgenic activity, glucocorticoid activity, PAH- and dioxin-like activity, lipid metabolism (PPAR $\gamma$ ), oxidative stress, pregnane X receptor (PXR) activity and five antibiotics activities. The selected endpoints and the corresponding bioassays are presented in

**TABLE 1**

*Target activities and in vitro bioassays selected for environmental hazard identification, with reference compounds for each bioassay.*

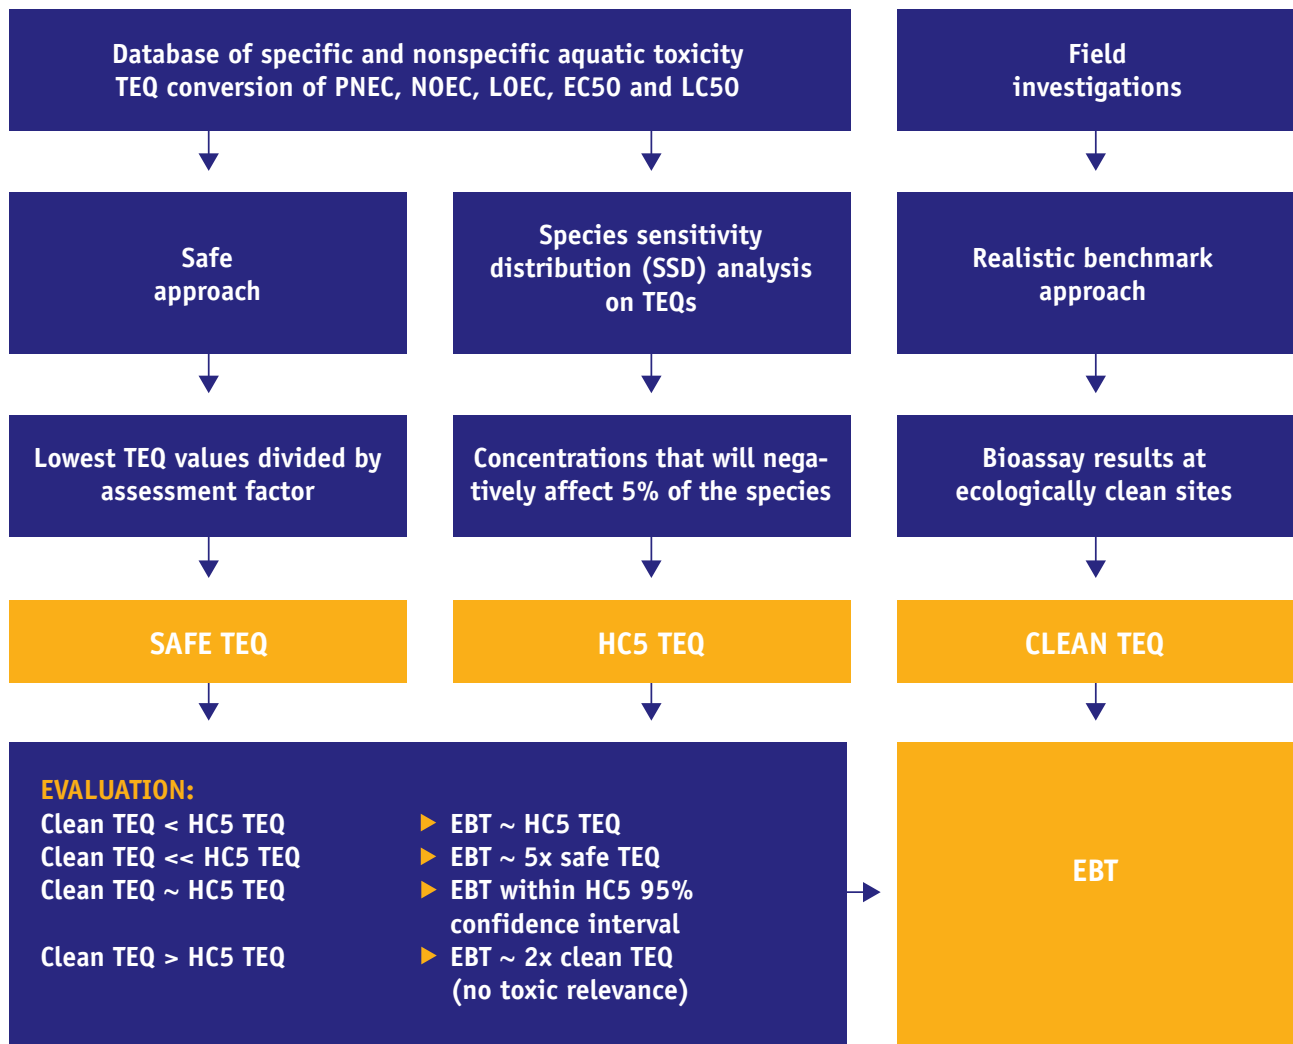

Activity detected	Bioassay	Reference Compound	(CAS)
Estrogenic	ERa CALUX	17- $\beta$ estradiol	50-28-2
Anti-androgenic	antiAR CALUX	Flutamide	13311-84-7
Dioxin and dioxin-like	DR CALUX	2,3,7,8-TCDD	1746-01-6
Glucocorticoid	GR CALUX	Dexamethasone	50-02-2

Toxic PAHs	PAH CALUX	Benzo[a]pyrene	50-32-8
Oxidative stress	Nrf2 CALUX	Curcumin	458-37-7
Pregnane X receptor	PXR CALUX	Nicardipine	54527-84-3
Antibiotics activities	Aminoglycosides	Neomycin	1404-04-2
	Macrolides & $\beta$ -Lactam	Penicillin	61-33-6
	Sulphonamides	Sulfamethoxazole	723-46-6
RIKILT WaterSCAN	Tetracyclines	Oxytetracycline	79-57-2
	Quinolones	Flumequine	42835-25-6

The EBTs developed in the present study will be incorporated in a model called “SIMONI”, which will be used to investigate the micro-chemical quality of the water (Figure 1). Within this model, the hazard identification (left site of the schedule in Figure 1) will be based on the responses of a battery of selected bioassays. The comparison between the bioassay responses and the EBTs will allow the classification of the investigated sites in low risk or potential risk for adverse ecological effects. Additional investigations will be conducted only on sites for which the bioassay responses indicate a potential ecological risk, and will be directed towards the identification of the toxic compounds in the samples through chemical analysis (van der Oost, in preparation a).

## 2 METHODS

The derivation of EBTs for the selected CALUX bioassays and antibiotic activities will be based on a three-step approach. The first step is a selection of compounds that are known to trigger a response in the bioassay, with relative effect potencies (REPs) close to the reference compound, a literature search for toxicity data on these selected compounds, and conversion to their TEQ values of the respective reference compounds. Lowest TEQs of the toxic effects found (divided by an assessment factor) will be used as safe toxic equivalents concentration (safe TEQ). The second step was a species sensitivity distribution of all TEQ values in order to estimate the TEQ level that may cause an adverse effect to 5% of the species (HC5 TEQ). The HC5 TEQ should preferably be higher than or equal to the proposed low-risk effect-based trigger value (EBT). The last step was a benchmark with Waternet field data. A realistic EBT should be higher than the average effect observed at eight reference sites with a good ecological status (clean TEQ). In order to get a good discrimination between sites, the EBT should be exceeded only at a limited number of polluted sites. The steps that were followed for the definition of EBTs are summarized in Figure 2, and described in detail in the following paragraphs.

**FIGURE 2**  
Schematic representation of the steps taken for the design of environmental EBTs.

## 2.1 TOXICOLOGICAL DATABASE

A collection of available toxicological data is the first and necessary step on which every method that aims to set quality standards is based. In a classical single-chemical approach, data are collected for the compound under study. However, due to the nature of the bioassays, it was necessary to follow a different approach. Since bioassays are effect-based tools that measure activities caused by a mixture of available compounds in a sample, the nature of the compounds that cause the observed effect remains unknown. The measured activity is expressed as *toxic equivalent* (TEQ) concentration to a reference compound, i.e. the equivalent concentration of a reference compound that would cause the same observed effect as the (un)known mixture of compounds present in the investigated sample. The reference compound is a chosen representative of a certain activity and is specific for each bioassay (see Table 1 for reference compounds of all selected bioassays). Additionally, different substances can be more or less potent in triggering a response than the corresponding reference compound. The concept of *relative effect potencies* (REPs) is used to account for these differences. REPs can be calculated by dividing the effect concentration of the reference compound by the concentration of another compound that is required to produce a similar effect. The TEQ concentration of a compound can thus be calculated by multiplying the actual concentration by its REP value.

Since a search of toxicological data for only the reference compounds is unreliable to set relevant EBTs, we included a selection of other compounds that are able to trigger a response in each bioassay. The compounds were selected based on their REPs. A complete list of the selected compounds and their REPs is presented in Appendix I. For all toxicological endpoints a search in scientific literature and toxicological databases was conducted to establish toxicity data of all selected compounds in water organisms at different trophic levels. Toxicity data were classified in five groups, i.e. PNEC (Predicted No-effect Concentration), NOEC (No Observed Effect Concentration), LOEC (Lowest Observed Effect Concentration), EC50 (50% Effect concentrations) and LC50 (concentrations lethal to 50% of the test organisms). The complete dataset of all toxicity data that were used for this study is presented in Appendix II. All toxicity data were converted to TEQ concentrations of the respective reference compounds by multiplication with the REPs. According to the precautionary principle, chronic toxicity was considered the most relevant for environmental risk assessment. In order to compare chronic with acute data some data conversion was needed.

**Assumption 1:** the focus of the trigger value design will be on chronic toxicity; in order to compare all toxicity data, acute data were converted in chronic data by dividing them by an assumed acute-to-chronic ratio of 10 (Durand et al., 2009). Since there are no strict definitions for acute and chronic exposure times, an assumption of the criteria for chronic exposure for different taxa had to be estimated.

**Assumption 2:** the estimated durations of chronic experiments for different groups of organisms are listed in Table 2; toxicity data of experiments with shorter exposure times are divided by a safety factor of 10 (i.e., assumption 1: acute-to-chronic concentration ratio).

**Assumption 3:** since chemicals with very low relative effect potencies (REPs) will give extremely low TEQ values, a certain restriction was needed for a realistic hazard identification; in order to compare the REP impact, all calculations for each EBT were performed on two chemical selections: the REP1 group included compounds with REPs > 0.1, while the REP2 group included compounds with REPs > 0.001.

The REPs for the CALUX bioassays were provided by BDS (BioDetection Systems, Amsterdam, The Netherlands), calculated from EC10 results of the different compounds. The REPs for the detection of antibiotic activity were estimated from the detection limits of the selected compounds. The RIKILT WaterScan and similar methods, such as RIKILT MeatScan or NDKT (New Dutch kidney test), are based on the growth inhibition of certain microorganisms after exposure to the samples. It was assumed that the detection limits of the antibiotics, i.e. the minimum concentrations that cause a detectable growth inhibition, corresponded to their potencies. Therefore, the REPs were estimated by dividing the detection limit of the ref-

erence compound by the detection limit of the considered compound. REPs were calculated from the detection limits of the RIKILT WaterScan method or those reported by Pikkemaat et al. (2008) for RIKILT MeatScan or NDKT. All REPs for each bioassay that were used for the present study are presented in APPENDIX I.

**TABLE 2**

*Criteria applied in the present study to estimate chronic exposure.*

Organism	Chronic exposure (days)
Protozoa	≥ 1
Bacteria	
Fungus	
Polyp	≥ 4

## 2.2 SAFE APPROACH (SAFE TEQ)

According to the precautionary principle it is relevant to define “safe” TEQs that indicate no risk levels of active compounds to the ecosystem. The lowest TEQs concentrations for each toxicological endpoint (PNEC, NOEC, LOEC, EC50 and LC50) were selected and divided by an assessment or safety factor (AF), which ranged for 1 to 100 according to the toxic endpoint considered (see Assumption 4: Table 3).

**Assumption 4:** assessment factors to estimate save biological activities by extrapolation of five different toxic endpoints are listed in Table 3.

**TABLE 3**

*Assessment factors (AFs) applied in the present study to convert toxicity data to assumed save levels.*

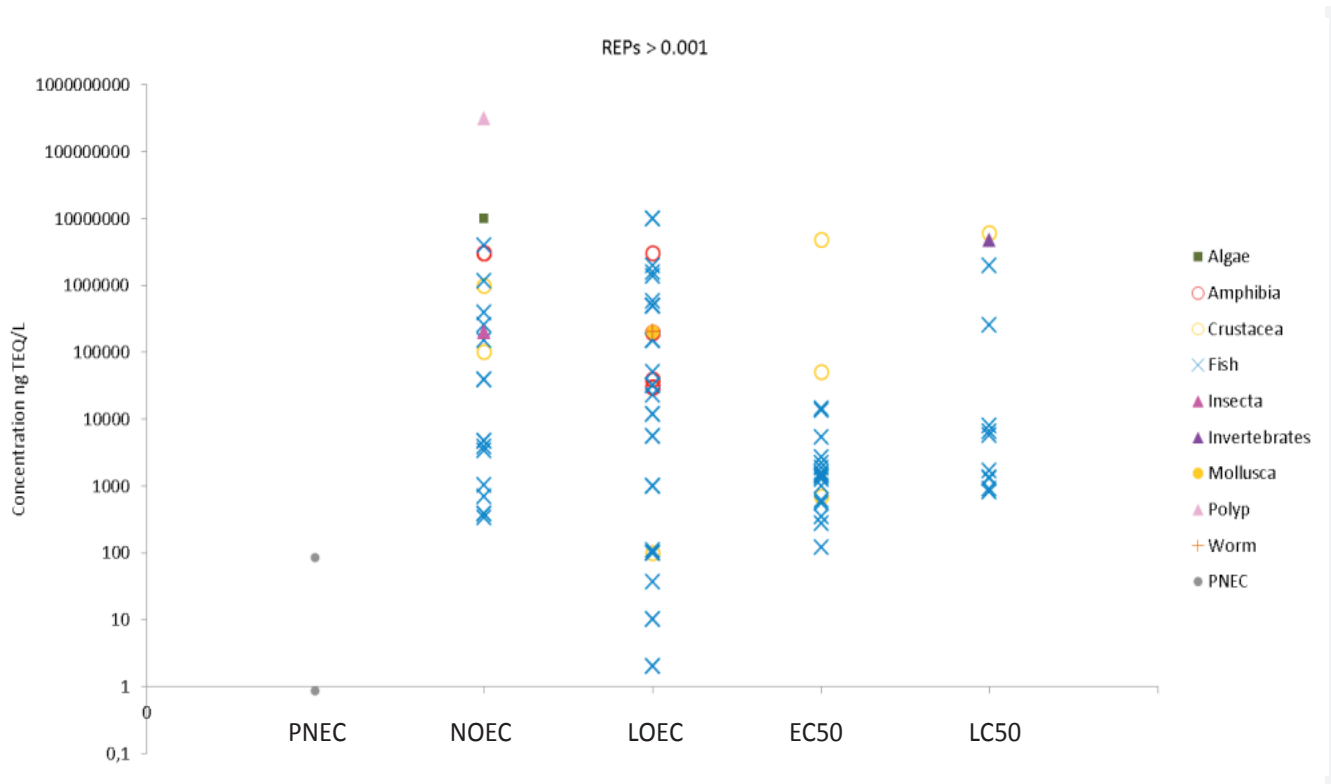

Endpoint	AF
PNEC	1
NOEC	1
LOEC	5
EC50	10
LC50	100

The lowest of all chronic toxicity values found in the literature, divided by their respective AFs, was considered as a safe value for water organisms and defined as the “safe” toxic equivalents concentration (safe TEQ). As an illustration of the ‘save approach’, all collected toxicity data for dioxin-like compounds of the REP2 group are presented in Figure 3. The lowest LOEC (divided by assessment factor 5) was used as the safe TEQ. Since these “no risk” safe TEQs will be exceeded at most moderately polluted sites, a more realistic approach was followed in order to define a “low risk” effect-based trigger value (EBT). This approach will be described in the next paragraphs.

Graphic representations of all collected toxicity data that were used for the EBT design for all bioassays (both REP1 and REP2 groups) are presented in Appendix IV.

**FIGURE 3**

*Toxicity dataset for dioxin-like compounds with REPs > 0.001.*

### 2.3 SPECIES SENSITIVITY DISTRIBUTION ANALYSIS (HC5 TEQ)

A more realistic trigger value approach ('low risk' instead of 'no risk') was based upon a Species Sensitivity Distribution (SSD) analysis (Posthuma et al., 2002). SSD curves are usually generated by fitting the distribution of log-transformed toxicological data (usually NOEC, EC50 or LC50) of several species for a single compound. When more data are available for the same compound in the same species, an average toxic concentration is used for the SSD. The output of the SSD distribution can be used to determine the 5th percentile hazard concentration (HC5 TEQ), which represents the concentration of the investigated compound that will negatively affect 5% of the species.

In the present study an unusual SSD approach was applied, since toxicological data of various compounds that trigger a response in the same bioassay had to be included. Since it is impossible to generate SSD curves with data of different substances, we converted all toxicological data to TEQ concentrations of the reference compounds of the bioassay. This conversion allowed us to generate SSD curves with the collected toxicity data for all species and for each original compound. Average TEQ values were used if different toxicity values were available for the same compound in the same species. The SSD curves were preferably generated from EC50 TEQ values with the statistical software ETX 2.0 (Vlaardingen et al., 2004).

For the DR CALUX and GR CALUX, the amount of available EC50 values was insufficient to run the SSD analysis. As a consequence, a combination of NOEC, LOEC and EC50 TEQ values were used. Prior to the analysis, NOEC and LOEC values were multiplied by 10 and 2 respectively, in order to get an AFs of 10 like the EC50 (assumption 4, Table 3), to account for the differences between these toxicological endpoints. The HC5 TEQ-values that were determined by this approach were meant to be used as upper limits of the low-risk effect-based trigger values. In some cases, however, an EBT above the HC5 TEQ had to be defined, due to higher benchmark data at sites with a good ecological status.

As an illustration of the SSD approach, the SSD curve with collected toxicity data (pg TEQ/L) for dioxin-like compounds of the REP2 group are presented in Figure 4. The TEQ-level that is hazardous to 5% of the organisms can be estimated with the SSD curve (affected fraction 0.05). SSD curves of all collected toxicity data that were used for the EBT design for all bioassays (both REP1 and REP2 groups) are presented in Appendix V.

**FIGURE 4**  
*Species sensitivity distribution (SSD) for dioxin-like compounds with REPs > 0.001.*

#### 2.4 BENCHMARK APPROACH BIOASSAYS (CLEAN TEQ)

Another approach to obtain more realistic “low risk” EBTs was a benchmark with field data. This benchmark approach was primarily carried out with the results of bioassay monitoring at eight reference sites with a good ecological status. The rationale behind this approach was that the bioassay responses that were observed at sites with a good ecological status were not considered crucial for realistic overall risk estimations and should not indicate potential ecological hazards. Therefore the benchmark data were used to indicate the lower limits for the EBTs, the “clean TEQ”.

## 2.5 DERIVATION OF EBT

In the ideal case, the clean TEQ would be somewhere in between the safe TEQ and the HC5-TEQ, determined with SSD. Further refinement of EBT derivation was based upon evaluation of the safe, HC5 and clean TEQs according to following algorithms. If the clean TEQ was lower than the HC5 TEQ of the bioassay, than an EBT around the HC5 TEQ value was proposed. If the clean TEQ was much lower than the HC5 TEQ of the bioassay, than an EBT of approximately 5 times the safe TEQ was proposed. This factor ranges between 2 and 10, depending upon the strength of the dataset (data for many substances and many species) used to determine safe and HC5 TEQs. If the clean TEQ was close to the HC5 TEQ, than a value within the 95% confidence interval of HC5 TEQ was proposed as EBT. If the clean TEQ was much higher than the HC5 TEQ, than an EBT of approximately 2 times the clean TEQ was proposed, depending upon the strength of the dataset. This latter situation was typical for bioassays that are responsive to a wide array of chemicals, such as anti-AR, oxidative stress and PXR responses. EBT derived for these assays are not considered toxicologically relevant, but are used as indicators for overall chemical stress.

The bioassay analyses for the benchmark approach were performed according to validated standard protocols, as described by Van der Oost et al. (in preparation b). The modes of action (MOA) and toxicological relevance of the various bioassays are described in the introduction.

### 3 RESULTS

The complete dataset of the collected toxicity data is presented in Appendix II. The lowest toxic concentrations found for five endpoints (PNEC, NOEC, LOEC, EC50 and LC50) are summarized for each bioassay in Appendix III.

#### 3.1 ESTROGENIC ACTIVITY

Release of endocrine disrupting compounds (EDC) in the water received much attention in the last decades, due to their ability to negatively affect aquatic populations. It was possible to find numerous studies in literature investigating the toxicity of estrogenic compounds, including biomarker endpoints (e.g. production of vitellogenin and changes in gene expression). The collected toxicity data for substances with estrogenic activity are presented in Appendix II A. The lowest toxic concentrations found for the five endpoints are presented in Appendix III.

##### Safe approach

Graphic representations of the collected toxicity values for the REP1 and REP2 groups are presented in Appendix IV as estradiol equivalents per liter water (EEQ). In the REP1 group, the lowest value found was a PNEC of 0.035 ng/L for 17 $\alpha$ -Ethinyl estradiol (James et al., 2014). However, 17 $\alpha$ -Ethinyl estradiol presents a relative potency of 1.56, and the PNEC, once transformed in EEQ, was equal to 0.055 ng EEQ/L. The lowest LOEC found was 0.5 ng/L of 17 $\alpha$ -Ethinyl estradiol for zebrafish (*Danio rerio*) after acute exposure (Colman et al., 2009). This value was multiplied by the acute to chronic ratio of 0.1 and transformed in EEQ. This resulted in a final value of 0.078 ng EEQ/L. After application of a safety factor of 5, a safe TEQ of 0.016 ng EEQ/L was proposed. In the REP2 group the safe TEQ was based on the lowest LOEC of 3.3 ng/L for rainbow trout (*Oncorhynchus mykiss*) after chronic exposure to estrone (Thorpe et al., 2003) with a REP of 0.01. This resulted in a TEQ value of 0.033 ng EEQ/L that was divided by a safety factor of 5, which lead to a proposed safe TEQ value of 0.007 ng EEQ/L.

##### SSD

The SSD curves for the REP1 and REP2 groups are presented in Appendix V. The SSD analysis for the REP1 group resulted in a HC5 TEQ equal to 0.47 ng EEQ/L (95% confidence interval from 0.009 to 6.2 ng EEQ/L). The SSD analysis for the REP2 group resulted in a HC5 TEQ equal to 0.52 ng EEQ/L (95% confidence interval from 0.019 to 5.4 ng EEQ/L).

##### Benchmark approach

The ER CALUX responses for estrogenic activity at 8 sites with good ecological status are presented in Figure 5. The clean TEQ was 0.06 ng EEQ/L.

**FIGURE 5**

Bioassay responses for estrogenic activity (ng EEQ/L) at eight sites with good ecological status.

Based on the benchmark values and after evaluation of bioassays responses at clean, moderately polluted and heavily polluted sites (Table 4B), we propose a low risk EBT for overall estrogenic activity of 0.5 ng EEQ/L that resembles the HC5 TEQ values of both REP groups. This trigger value is exceeded at sites affected by effluents from waste water treatment plants (wwtp), two moderately polluted and eleven heavily polluted sites.

### 3.2 ANTI-ANDROGENIC ACTIVITY

The complete set of collected toxicity data of anti-androgenic substances is presented in Appendix II B. The lowest toxic concentrations found for the five endpoints are presented in Appendix III. The group of compounds that can inhibit the human androgen receptor and block its action (anti-androgenic response) is very heterogeneous (see Appendix I). It includes estrogenic compounds (e.g. 17 $\alpha$ -ethinylestradiol and estradiol), pesticides (e.g. alachlor, triclosan, vinclozolin), synthetic materials (e.g. bisphenol A and phthalates) and non-ionic surfactants (alkylphenoles).

#### Safe approach

Graphic representations of the collected toxicity values for the REP1 and REP2 groups are presented in Appendix IV as flutamide equivalents per liter (F1EQ/L). The values used for the definition of a safe TEQ did not differ in the REP1 and REP2 groups. The lowest value found in literature was a PNEC for benzo[a]pyrene equal to 0.0017  $\mu$ g/L (OSPAR Agreement, 2014-05). Since benzo[a]pyrene has a REP of 1 in the antiAR CALUX, this PNEC is equal to 0.0017  $\mu$ g FEQ/L. However, the safe TEQ was set based on the lowest LC50 of 0.016  $\mu$ g/L for endosulfan for the copepod *Mesocyclops longisetus* after acute exposure (Gutierrez et al., 2013). The transformed chronic value was equal to 0.005  $\mu$ g F1EQ/L. Assuming a safety factor of 100 for the LC50 endpoint, the final proposed safe TEQ is equal to 0.05 ng F1EQ/L.

#### SSD

The SSD curves for the REP1 and REP2 groups are presented in Appendix V. The SSD analysis for the REP1 group resulted in a HC5 TEQ equal to 0.29  $\mu$ g F1EQ/L (95% confidence interval from 0.1 to 0.6  $\mu$ g F1EQ/L). The SSD analysis for the REP2 group resulted in a HC5 TEQ equal to 0.13  $\mu$ g F1EQ/L (95% confidence interval from 0.05 to 0.27  $\mu$ g F1EQ/L).

#### Benchmark approach

The anti-AR CALUX responses for estrogenic activity at 8 sites with good ecological status are presented in Figure 6. The mean anti-AR response was equal to 4.55  $\mu$ g F1EQ/L.

**FIGURE 6**

Bioassay responses for anti-androgenic activity ( $\mu$ g FEQ/L) at eight sites with good ecological status.

The range of toxic concentrations collected for compounds that exhibit anti-androgenic activity was very broad, reflecting the different nature of the substances taken into consideration. In this contest, the benchmark approach was considered even more important, since an approach based on the HC5 TEQ value of the SSD analysis would lead to an insufficient discrimination between sites (EBT would be exceeded at all sites). Based on the reference benchmark values and after evaluation of Waternet bioassays responses at polluted sites (Table 4B), we propose a low risk EBT for overall anti-androgenic activity of 25 µg F1EQ/L, which is much higher than the predicted HC5 TEQ and the proposed safe TEQ. This trigger value was exceeded at one of the reference sites, four moderately polluted sites and five heavily polluted sites.

### 3.3 DIOXIN AND DIOXIN-LIKE ACTIVITY

A complete set of collected toxicity data of substances with dioxin-like activity is presented in Appendix II C. The lowest toxic concentrations found for the five endpoints are presented in Appendix III. Dioxin and dioxin-like compounds are poorly water-soluble. They tend to accumulate in organism due to bioaccumulation or biomagnification. Most of the studies reported nominal concentrations of exposure, which may lead to an underestimation of the risk connected to the exposure of aquatic organisms to this group of compounds.

#### Safe approach

Graphic representations of the collected toxicity values for compounds in the REP1 and REP2 groups are presented in Appendix IV as 2,3,7,8-tetrachloro dibenzodioxin (TCDD) equivalent per liter (TEQ/L). In both REP1 and REP2 group, the lowest value found was a LOEC of 2 pg/L for rare minnow (*Gobiocypris rarus*) after chronic exposure to 2,3,7,8-TCDD (Wu et al., 2001), which is equal to the TEQ concentration, since 2,3,7,8-TCDD is the reference compound for the DR CALUX. A safety factor of 5 for LOEC was applied to this value, so the proposed safe TEQ is equal to 0.4 pg TEQ/L.

#### SSD

The SSD curves for the REP1 and REP2 groups are presented in Appendix V. The SSD analysis for the REP1 group resulted in a HC5 equal to 36 pg TEQ/L (95% confidence interval from 1.7 to 308 pg TEQ/L). The SSD analysis for the REP2 group resulted in a HC5 equal to 137 pg TEQ/L (95% confidence interval from 15 to 736 pg TEQ/L).

#### Benchmark approach

The DR CALUX responses for dioxin and dioxin-like activity at 8 sites with good ecological status are presented in Figure 7. The clean TEQ was equal to 13.2 pg TEQ/L.

**FIGURE 7**

*Bioassay responses for dioxin and dioxin-like activity (pg TEQ/L) at eight sites with good ecological status.*

Based on this values and after evaluation of Waternet bioassays responses at polluted sites (Table 4C), we propose a low risk EBT for overall dioxin-like activity of 50 pg TEQ/L, which is slightly higher than the HC5 TEQ of the REP1 group, but lower than the HC5 TEQ of the REP2 group. This trigger value is exceeded at seven polluted sites, six of which were considered to be moderately polluted.

### 3.4 GLUCOCORTICOID ACTIVITY

A complete set of collected toxicity data of compounds with glucocorticoid activity is presented in Appendix II D. The lowest toxic concentrations found for the five endpoints are presented in Appendix III. The toxic effects of glucocorticoids for the aquatic community have been poorly investigated. The dataset for both the REP1 and REP2 groups is limited if compared to others activities investigated in the present study. Most studies were conducted on fish, while information for other trophic levels is scarce or inexistent.

#### *Safe approach*

Graphic representations of the collected toxicity values for compounds in the REP1 and REP2 groups are presented in Appendix IV as dexamethasone equivalents per liter (DEQ/L). In both REP1 and REP2 group, the lowest value found was a LOEC of 100 ng/L for fathead minnow (*Pimephales promelas*) after chronic exposure to dexamethasone (Lalone et al., 2012), which is equal to the TEQ concentration, since dexamethasone is the reference compound for the GR CALUX. A safety factor of 5 for LOEC was applied to this value, so the proposed safe TEQ is equal to 20 ng DEQ/L. This safe TEQ is 3 orders of magnitude lower than the only PNEC found in literature for prednisone of 27,800 ng DEQ/L (Escher et al., 2011).

#### *SSD*

The SSD curves for the REP1 and REP2 groups are presented in Appendix V. The SSD analysis for the REP1 group resulted in a HC5 TEQ equal to 3236 ng DEQ/L (95% confidence interval from 80 to 29965 ng DEQ/L). The SSD analysis for the REP2 group resulted in a HC5 TEQ equal to 2145 ng DEQ/L (95% confidence interval from 116 to 14311 pg TEQ/L).

#### *Benchmark approach*

The GR CALUX at eight sites with good ecological status did not show any glucocorticoid activity above the detection limit of 1.2 ng DEQ/L.

Since no GR activity was observed at the clean reference sites, the bioassays responses at polluted sites (Table 4) were leading for the benchmark. We propose low risk EBT for overall glucocorticoid activity of 100 ng DEQ/L, which is five times higher than the safe TEQ of 20 ng DEQ/L. This EBT is only exceeded at three sites heavily affected by wwtp effluents.

### 3.5 OXIDATIVE STRESS

It was not possible to find any toxicity data for aquatic community for the reference compound of this bioassay (i.e. curcumin). However, information was available on the many other compounds that cause oxidative stress to cells and trigger a response in Nrf2 CALUX. The complete set of collected toxicity data of compounds causing oxidative stress is presented in Appendix II E. The lowest toxic concentrations found for the five endpoints are presented in Appendix III.

#### *Safe approach*

Graphic representations of the collected toxicity values for the REP1 and REP2 groups are presented in Appendix IV as curcumin equivalent per liter water (CEQ/L). In the REP1 group, the safe TEQ was based on the lowest EC50 of 0.42 µg/L for zebrafish (*Danio rerio*), after acute exposure to retinoic acid (Selderslaghs et al., 2012). This value was multiplied for an acute to chronic ratio of 0.1 and multiplied by the corresponding REP. The final TEQ value was equal to 0.007 µg CEQ/L. This value was divided by a safety factor of 10 for EC50, which resulted in a proposed safe TEQ of 0.0007 µg CEQ/L. This safe TEQ is one order of magnitude lower than the lowest PNEC of 0.023 µg CEQ/L for carbenzadim (Oekotoxzentrum website, EAWAG).

The lowest values found for all the toxic endpoints in the REP2 group were for estradiol, due to the fact that this compound has a relative potency of 0.06. The proposed safe TEQ of 0.006 ng CEQ/L was based on the lowest NOEC of 0.001 µg/L for *Oryzias latipes* (*Japanese Medaka*) after acute exposure to estradiol (Lee et al., 2012).

### SSD

The SSD curves for the REP1 and REP2 groups are presented in Appendix V. The SSD analysis for the REP1 group resulted in a HC5 TEQ equal to 0.7 µg CEQ/L (95% confidence interval from 0.2 to 2.2 µg CEQ/L). The SSD analysis for the REP2 group resulted in a HC5 TEQ equal to 0.034 µg CEQ/L (95% confidence interval from 0.008 to 0.11 µg CEQ/L).

### Benchmark approach

The Nrf2 CALUX responses for oxidative stress at 7 sites with good ecological status are presented in Figure 8. The clean TEQ was equal to 4.25 µg CEQ/L.

**FIGURE 8**

*Bioassay responses for Nrf2 oxidative stress (µg CEQ/L) at seven sites with good ecological status.*

The range of toxic concentrations collected for compounds that cause oxidative stress was (like anti-AR compounds) very broad, reflecting a different nature and toxicity. The low HC5 TEQ value that was found was not useful for designing a realistic EBT, because it would be exceeded at all unpolluted sites. Based upon the mean benchmark value at the reference sites, we propose a low risk EBT for overall oxidative stress activity of 10 µg CEQ/L, which is much higher than the predicted HC5 TEQ values. This EBT was not yet performed at many polluted sites, and no exceedances have been observed thus far (Table 4C).

### 3.6 TOXIC PAHS

The complete set of collected toxicity data of toxic PAHs is presented in Appendix II F. The lowest toxic concentrations found for the five endpoints are presented in Appendix III. As in the case of dioxin and dioxin-like compounds, PAHs are lipophilic compounds that tend to accumulate in soil, organic particulate and tissues rather than in water. For this reason, the concentration of this class of pollutants should be measured during and/or at the end of the exposure period. However, the majority of the reviewed studies reported nominal concentrations of exposure, which may lead to an underestimation of the risks.

### Safe approach

Graphic representations of the collected toxicity values for the REP1 and REP2 groups are presented in Appendix IV as benzo[a]pyrene equivalents per liter water (BEQ/L). In the REP1 group the lowest value found was a PNEC of 0.17 ng/L for

benzo[a]pyrene (OSPAR Agreement, 2014-05). This value was used to set a safe TEQ of 0.17 ng BEQ/L. In the REP2 group the lowest value found was a LOEC of 0.02 ng/L for *Gobiocypris rarus* (Rare minnow) after chronic exposure to benzo[a]pyrene (Wu et al., 2001). This value was divided by a safety factor of 5 for LOEC, which resulted in a proposed safe TEQ of 0.008 ng BEQ/L.

### SSD

The SSD curves for the REP1 and REP2 groups are presented in Appendix V. The SSD analysis for the REP1 group resulted in a HC5 TEQ equal to 47 ng BEQ/L (95% confidence interval from 2 to 368 ng BEQ/L). The SSD analysis for the REP2 group resulted in a HC5 TEQ equal to 41 ng BEQ/L (95% confidence interval from 2.5 to 254 ng BEQ/L).

### Benchmark approach

The PAH CALUX responses at 8 sites with good ecological status are presented in Figure 9. The clean TEQ was equal to 62.7 ng BEQ/L.

**FIGURE 9**

Bioassay responses for toxic PAHs (ng BEQ/L) at eight sites with good ecological status.

Based on the clean TEQ value and after evaluation of Waternet bioassays responses at polluted sites (Table 4C), we propose a low risk EBT for overall PAH activity of 150 ng BEQ/L. This EBT was above the estimated HC5 TEQ values, but falls within the HC5 95% confidence intervals. The EBT was exceeded at four moderately polluted sites, while not many measurements were performed at heavily polluted sites.

### 3.7 PPAR $\gamma$ RECEPTOR

The complete set of collected toxicity data of PPAR $\gamma$  inducing compounds is presented in Appendix II. The lowest toxic concentrations found for the five endpoints are presented in Appendix III. The *in vitro* PPAR $\gamma$  CALUX is able to detect compounds that activate the PPAR gamma receptor, including several classes of aquatic contaminants, such as organotins and perfluorinated compounds.

### Safe approach

Graphic representations of the collected toxicity values for the REP1 and REP2 groups are presented in Appendix IV as rosiglitazone equivalent per liter water (REQ/L). For the REP1 group the safe TEQ was based on the lowest EC50 found of 424 ng/L for zebrafish (*Danio rerio*) after acute exposure to retinoic acid (Selderslaghs et al., 2012). This value was multiplied by an acute to chronic ratio of 0.1 and transformed to a TEQ value equal to 13.4 ng REQ/L. This value was then divided by

a safety factor of 10, which resulted in a safe TEQ of 1.34 ng REQ/L. In the REP2 approach the safe TEQ was based on the lowest PNEC of 0.14 ng/L for dibenzo[a,h] anthracene (OSPAR Agreement, 2014-05). After TEQ transformation a value of 0.00014 ng REQ/L was defined as the safe TEQ.

### SSD

The SSD curves for the REP1 and REP2 groups are presented in Appendix V. The SSD analysis for the REP1 group resulted in a HC5 TEQ equal to 45 ng REQ/L (95% confidence interval from 0.8 to 371 ng REQ/L). The SSD analysis for the REP2 group resulted in a HC5 TEQ equal to 0.3 ng REQ/L (95% confidence interval from 0.002 to 6.9 ng REQ/L).

### Benchmark approach

The PPAR $\gamma$  CALUX responses for at 8 sites with good ecological status are presented in Figure 10. The clean TEQ was equal to 4.37 ng REQ/L.

**FIGURE 10**

*Bioassay responses of PPAR $\gamma$  lipid metabolism (ng REQ/L) at eight sites with good ecological status.*

Based upon the benchmark of unpolluted reference sites and after evaluation of Waternet bioassays responses at polluted sites (Table 4C), we propose a low risk EBT for peroxisome proliferation of 10 ng REQ/L. This value is higher than the HC5 TEQ of the REP2 group, but lower than the HC5 TEQ calculated with REP1 compounds. The ETB was exceeded at two moderately polluted sites and seven heavily polluted sites.

### 3.8 PREGNANE X RECEPTOR

The complete set of collected toxicity data of PXR inducing compounds is presented in Appendix II H. The lowest toxic concentrations found for the five endpoints are presented in Appendix III. The PXR CALUX is able to detect many WFD priority compounds, including pesticides, PAHs and alkyl phenols.

### Safe approach

Graphic representations of the collected toxicity values for the REP1 and REP2 groups are presented in Appendix IV as nicarbidine equivalent per liter water (NEQ/L). In both REP1 and REP2 groups the safe TEQ was based on the lowest LOEC found of 1 ng/L for *Daphnia magna* after acute exposure to chlorpyrifos-ethyl (Ha and Choi, 2009). This value was multiplied by an acute to chronic ratio of 0.1 and transformed to a TEQ value equal to 0.020 ng NEQ/L. This value was then divided by a safety factor of 5 for LOEC, which resulted in a safe TEQ of 0.004 ng NEQ/L. The safe TEQ

is 1 order of magnitude lower than the lowest PNEC found for benzo(k)fluoranthene, equal to 0.03 ng NEQ/L (OSPAR Agreement, 2014-05).

### SSD

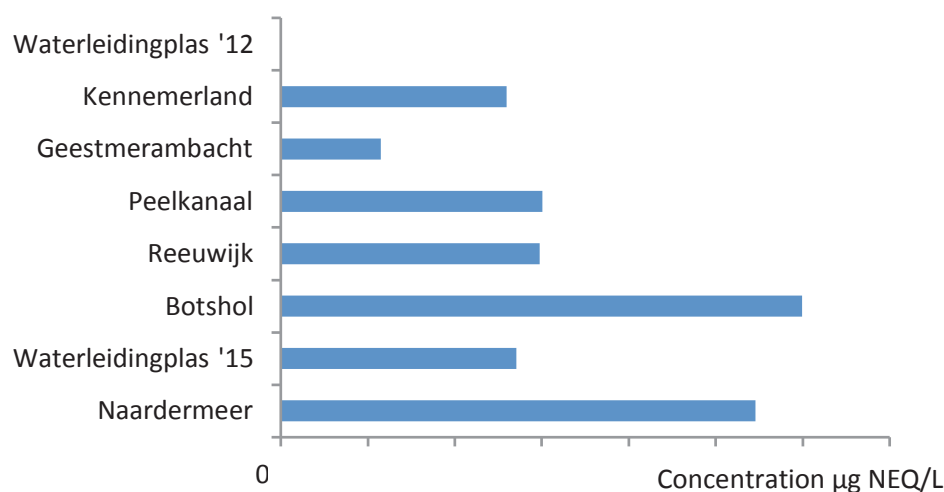

The SSD curves for the REP1 and REP2 groups are presented in Appendix V. The SSD analysis for the REP1 group resulted in a HC5 TEQ equal to 7 ng NEQ/L (95% confidence interval from 1 to 30 ng NEQ/L). The SSD analysis for the REP2 group resulted in a HC5 TEQ equal to 8 ng NEQ/L (95% confidence interval from 2 to 24 ng NEQ/L).

### Benchmark approach

The PXR CALUX responses for biotransformation activity at 7 sites with good ecological status are presented in Figure 11. The clean TEQ was equal to 1.71 µg NEQ/L.

**FIGURE 11**

*Bioassay responses of PXR biotransformation activity (µg NEQ/L) at seven sites with good ecological status.*

The range of toxic concentrations collected for compounds that cause elevated PXR biotransformation was (like for anti-AR and oxidative stress endpoints) very broad, reflecting a different nature and toxicity. The low HC5 TEQ value that was found was not useful for designing a realistic EBT, because it would be exceeded at all unpolluted sites. Based upon the mean benchmark value at the reference sites, we propose a low risk EBT for overall PXR activity of 3 µg CEQ/L, which is much higher than the predicted HC5 TEQ values. This bioassay was not yet performed at many polluted sites, and only three exceedances have been observed thus far (Table 4C).

## 3.9 ANTIBIOTICS ACTIVITIES

According to their mode of action (MOA) antibiotics are generally divided into five classes: amidoglycosides, macrolides & β-lactams, sulfonamides, tetracyclines and quinolones. Since the bioassay determines the activities of all classes of antibiotics five separate ETVs were developed.

### 3.9.1 Aminoglycosides

The complete set of collected toxicity data for compounds with aminoglycosides activity is presented in Appendix II I.1. The lowest toxic concentrations found for the five endpoints are presented in Appendix III.

#### *Safe approach*

There were no compounds within this group of antibiotics with REPs lower than 0.1. Graphic representation of the collected toxicity values for the REP1 group is presented in Appendix IV as neomycin equivalents per liter water (NEQ/L). The safe TEQ was based on the lowest PNEC found of 300 ng/L for neomycin (Park and Choi, 2008). Neomycin is the reference compound for this group of antibiotic. As a consequence, the TEQ value was also equal to 300 ng NEQ/L. This PNEC was calculated applying an assessment factor of 100 on the neomycin chronic NOEC for *Daphnia magna* (0.03 mg/L) (Park and Choi, 2008). This value is therefore the proposed safe TEQ for aminoglycosides group.

#### *SSD*

The SSD curve for the REP1 group is presented in Appendix V. The SSD analysis resulted in a very high HC5 TEQ equal to 33222 ng NEQ/L (95% confidence interval from 1546 to 219614 ng NEQ/L).

#### *Benchmark approach*

No detectable aminoglycosides activity (>90 ng NEQ/L) was found at the eighth clean reference sites. Moreover, most of the aminoglycosides activities found in the environment by Waternet in the years 2010-2014 were below detectable levels, apart from some sites that were affected by wwtp effluents (Table 4B).

Mainly based upon the benchmark, we propose a low-risk EBT of 500 ng NEQ/L, which is twice the safe TEQ of 300 ng NEQ/L. The EBT was only exceeded at two sites with a significant wwtp influence (Table 4B).

### **3.9.2 Macrolides and $\beta$ -Lactams**

The complete dataset of collected toxicity values of compounds with macrolides activity is presented in Appendix II I.2. The lowest toxic concentrations found for the five endpoints are presented in Appendix III.

#### *Safe approach*

Graphic representations of the collected toxicity values for the REP1 and REP2 groups are presented in Appendix IV as penicillin equivalents per liter water (PEQ/L). In the REP1 group the safe TEQ was based upon the lowest PNEC found of 3.7 ng/L for amoxicillin (Jones et al., 2002). The safe TEQ for this group of antibiotics was derived after transformation to a TEQ value of 2.22 ng PEQ/L. In the REP2 group, the safe TEQ was equal to 1.8 ng PEG/L, calculated from the lowest EC50 for *Microcystis aeruginosa* after chronic exposure to 18 ng/L tiamulin (Halling-Sorensen, 2000).

#### *SSD*

The SSD curves for the REP1 and REP2 groups are presented in Appendix V. The SSD analysis for the REP1 group resulted in a HC5 TEQ equal to 2615 ng PEQ/L (95% confidence interval from 96 to 23135 ng PEQ/L). The SSD analysis for the REP2 group resulted in a HC5 TEQ equal to 98 ng PEQ/L (95% confidence interval from 12.9 to 470 ng PEQ/L).

#### *Benchmark approach*

No detectable activities of macrolides and  $\beta$ -lactams (>1.4 PEQ/L) were found at the eight clean reference sites. The concentrations of macrolides and  $\beta$ -lactams antibiotics (e.g. penicillin) collected by Waternet passive sampling demonstrate that this group of antibiotics is the most commonly found in Dutch waters (Table 4B), with detectable concentrations especially at sites influenced by wwtp effluents.

Considering these data and the low safe TEQ, a low risk EBT of 50 ng/L is proposed. The proposed EBT is lower than both HC5 TEQ estimations, but the lower limit of the HC5 95% confidence interval for the REP2 group is below this EBT. The EBT was exceeded at four sites with a significant wwtp influence (Table 4B).

### 3.9.3 Sulfonamides

The complete dataset of collected toxicity values of compounds with sulfonamides activity is presented in Appendix II I.3. The lowest toxic concentrations found for the five endpoints are presented in Appendix III.

#### *Safe approach*

There were no compounds considered for this bioassay with REPs lower than 0.1. Graphic representation of the collected toxicity values for the REP1 group is presented in Appendix IV as sulfamethoxazole equivalents per liter water (SEQ/L). The safe TEQ was based on the lowest LOEC found of 1000 ng/L for zebra fish (*Danio rerio*) after acute exposure to sulfadiazine (Lin et al., in press). The TEQ value was equal to 50 ng SEQ/L. After application of a safety factor of 5 for LOEC, the proposed safe TEQ for this group of antibiotics is equal to 10 ng SEQ/L.

#### *SSD*

The SSD curve for the REP1 group is presented in Appendix V. The SSD analysis resulted in a HC5 TEQ equal to 67037 ng SEQ/L (95% confidence interval from 24675 to 148222 ng SEQ/L).

#### *Benchmark approach*

A sulfonamide activity of 37 ng SEQ/L was found in one of the reference sites, while activities at the other seven clean sites were all below the detection limit of 2 ng SEQ/L. The clean TEQ was equal to 4.6 SEQ/L.

Considering the high HC5 TEQ values, we propose a low risk EBT of 100 ng SEQ/L, which is ten times the safe TEQ. The EBT was exceeded at seven sites with a significant wwtp influence (Table 4B).

### 3.9.4 Tetracyclines

The complete dataset of collected toxicity values of compounds with tetracycline activity is presented in Appendix II I.4. The lowest toxic concentrations found for the five endpoints are presented in Appendix III.

#### *Safe approach*

Graphic representations of the collected toxicity values for the REP1 and REP2 groups are presented in Appendix IV as oxytetracycline equivalents per liter water (OEQ/L). In both REP1 and REP2 groups the safe TEQ was based upon the lowest PNEC found of 170 ng/L for oxytetracycline (Park and Choi, 2008). As for sulfonamides, these authors used the lowest value they could find, in this case the acute LC50 of 0.17 mg/L for the algae *Selenastrum capricornutum* after 3 days of exposure, reported by Nunes et al. (2005), and applied a safety factor of 1000 to calculate the resulting PNEC. The corresponding TEQ value and proposed safe TEQ for this group of antibiotics is thus equal to 170 ng OEQ/L.

#### *SSD*

The SSD curves for the REP1 and REP2 groups are presented in Appendix V. The SSD analysis for the REP1 group resulted in a HC5 TEQ equal to 32931 ng OEQ/L (95% confidence interval from 9837 to 83368 ng OEQ/L). The SSD analysis for the REP2 group resulted in a HC5 TEQ equal to 27275 ng OEQ/L (95% confidence interval from 8292 to 68544 ng OEQ/L).

#### *Benchmark approach*

No detectable tetracycline activity (>22 ng OEQ/L) was found at the eighth clean reference sites. Tetracyclines-like environmental activities were above detection limit in four Waternet samples, with a maximum of 104 ng OEQ/L close to a wwtp discharge (Table 4B). We propose a low risk EBT for tetracyclines activity of 250 ng OEQ/L, which is about twice the safe TEQ. Tetracycline activities above the detection limit were only observed at five sites, all below the proposed EBT (Table 4B).

### 3.9.5 Quinolones

The complete dataset of collected toxicity values of compounds with quinolone activity is presented in Appendix II I.5.

The lowest toxic concentrations found for the five endpoints are presented in Appendix III. Although it is not used as an antibiotic, triclosan data are also included because this substance induces a clear response in the quinolones bioassay. Triclosan is an antibacterial and antifungal substance often used in personal care products like soaps (Riva et al., 2012).

#### *Safe approach*

There were no compounds within this group with REPs lower than 0.1. Graphic representation of the collected toxicity values for the REP1 group is presented in Appendix IV as flumequine equivalents per liter water (FEQ/L). The safe TEQ was based on the lowest EC50 found of 530 ng/L for the algae *Selenastrum capricornutum* after acute exposure to triclosan (Yang et al., 2008). The corresponding TEQ value was equal to 5.3 ng FEQ/L. The safe TEQ was established as 0.53 ng SEQ/L after application of a safety factor of 10 for EC50.

#### *SSD*

The SSD curve for the REP1 group is presented in Appendix V. The SSD analysis resulted in a HC5 TEQ equal to 8759 ng FEQ/L (95% confidence interval from 2197 to 26050 ng FEQ/L).

#### *Benchmark approach*

No detectable quinolones activity (>44 ng FEQ/L) was found at any of the eighth clean reference sites. Considering the high HC5 TEQ and the low safe TEQ due to triclosan, a low risk EBT of 100 ng/L (i.e. 200x the safe TEQ value) is proposed for this group of antibiotics. Quinolones activity below the EBT was only detected three Waternet sites thus far (Table 4B), and the EBT was never exceeded.

### **3.10 Overview and evaluation of ebt development**

The effects measured in passive sampler extracts were converted to estimated water effect by a method proposed in Van der Oost et al. (in preparation b). Water TU or TEQ levels were divided by the proposed low-risk trigger values (EBT). It is demonstrated that EBTs are only exceeded at the clean reference sites, and that most EBT exceedance is observed at sites that were polluted by pesticides (Legmeerpolders) or in raw wwtp effluents (Amstelveen and Hilversum). The results of the benchmark studies at sites that were classified as clean, moderately polluted and heavily polluted, carried out by Waternet and STOWA, are presented in Table 4. This table is divided into three separate sections for A. bioassays for general toxicity (for which the EBT were not determined in this study), B. specific bioassays that were applied on the polar extracts of POCIS passive samplers, and C. specific bioassays that were applied on the non-polar extracts of silicon rubber passive samplers. All benchmark results are summarized in the heatmap of Table 5, and compared to the SIMONI scores that were calculated with the entire bioassay battery. A SIMONI score above 1 indicates a potential risk of the ecosystem due to micropollutant exposure.

The benchmark studies, together with the SSD analyses, were used to define low-risk trigger values that will be used for the environmental hazard identification of micropollutants. All relevant results for the determination of the proposed EBTs, using the compounds selected for both REP groups 1 (>0.1) and 2 (>0.001), are summarized in Table 6.

TABLE 4A

Benchmark results of relative bioassay responses (response/EBT) for general toxicity; orange = response above EBT, dark green = response below EBT; light green = no response; white = not measured.

## 4 DISCUSSION

---

Protection and restoration of chemical water quality is a primary goal to achieve, considering the fundamental ecological processes that take part in this environmental compartment. In order to improve the water quality by the most relevant measures, a more holistic and reliable monitoring of the water quality is needed. Many authors stressed out the necessity to improve the current monitoring programs using chemical analyses of selected target compounds, and highlight that bioanalytical tools can be applied to achieve this (Sanchez and Porcher, 2009; Allan et al., 2006; Cairns and van der Schalie, 1980; Connon et al., 2012; Poulsen et al., 2011; Greenwood et al., 2007). Several studies demonstrated the added value of bioassays to investigate the chemical quality of wastewater, surface water and drinking water (Kienle et al., 2011, Wolska et al., 2007, Macova et al., 2011, Zegura et al., 2009). Despite many advantages, bioanalytical tools are hardly used in regular monitoring programs, because there are no generally accepted methods for the interpretation of the data that are generated by effect measurements (biomarkers and bioassays). Hazard identification with bioanalytical tools could be applied as an initial screening to assess the microchemical water quality, provided that the effects could be classified. Effect-based trigger values that are able to discriminate between low risk and potential microchemical risks are needed for such a classification. The present study aims to be a first step towards the integration of bioassays in regulatory environmental processes. The primary objective of this study is to establish EBTs for a selection of inexpensive bioassays, targeting specific and reactive chemical activities in the water. The EBTs will be used to discriminate sites where chemical pollution poses a minor risk to aquatic community from sites where ecological risks may occur. Only the latter sites need to be further analyzed by more advanced chemical and toxicological analyses.

Routine monitoring with bioassays is still hampered by the lack of reliable interpretation guidelines. A challenge for scientists now is to provide effect-based trigger values (EBT) that allow regulators to link the test results to possible adverse effects on environmental or human health (Escher and Leusch, 2012). The fact that in many studies only a small percentage of the effect observed in a bioassay can be explained by known (chemically determined) substances makes it imperative to derive such EBT (Tang et al., 2013; Escher et al., 2013). A very limited amount of effect-based trigger values for water quality assessment can be found in literature.

Brand et al., (2013) derived some human health EBT for hormonal activity in drinking water. These EBT were derived to interpret *in vitro* CALUX bioassay results on estrogenic, androgenic, progestagenic and glucocorticoid activities. As a protocol to derive these EBT, the researchers used the reported ADI (acceptable daily intake), toxicokinetics information on bioavailability (protein binding), relative endocrine potencies and drinking water allocation factors of selected hormonal active compounds of interest.

Another approach for EBT derivation was followed by Tang et al. (2013) for an apical endpoint, the cytotoxicity measured by the bioluminescence inhibition in *Vibrio fischeri*. They proposed an algorithm for the derivation of effect-based water quality trigger values that was based on combined effects of mixtures of regulated chemicals, according to the concentration addition model. They used a QSAR approach to estimate the 50% effect concentrations (EC50) of the nonspecific mode of action of baseline toxicity. The effect-based water quality trigger value, EBT-EC50, was calculated with predicted mixture effect of all chemicals in a given guideline, divided by an extrapolation factor. The derived 'human health' EBT for drinking water was expressed as a relative enrichment factor (REF) of 3 to measure an EC50 (which is equal to 0.33 TU), which is less conservative than the 'environmental' EBT at REF 20 and 0.05 TU, proposed by Durand et al. (2009). The authors stated that the cytotoxicity based trigger value should not be used in isolation, but must be applied in conjunction with EBT targeting critical specific modes of action. Escher et al. (2013) used a similar strategy to derive an EBT for the oxidative stress response pathway with the AREC32 cell line. They derived an EBT that corresponded to a REF of 6 to measure an induction ratio of 1.5 (ECIR1.5), which means a 50% higher response than the blank control.

Hamers et al. (2010) obtained toxicity pathway profiles as toxicological 'fingerprints' for environmental samples, using

a bioassay battery with different modes of action. They used bioassays for genotoxicity, (anti)-estrogenic activity, thyroid activity, dioxin-like activity and nonspecific cell toxicity for hazard profiling and quality assessment of surface water sediments. Three potential approaches were described. In the first approach, toxicity profiles were translated into hazard profiles, indicating the relative distance to the desired or acceptable sediment quality status for each toxic mode of action. In the second approach, toxicity profiles were translated into ecological risk profiles indicating the ratio between the measured bioassay responses and the responses considered safe for environmental health. In the third approach, toxicity and hazard profiles were used to select samples with unusually high bioassay responses for further in-depth effect-directed analysis (EDA). A combination of the second and third of these approaches is most similar to the strategy that is proposed in the present paper (Figure 1). The main difference is that for our strategy a suite of effect-based trigger values are derived for 'low environmental risks' (confirmed at sites with good ecological status), instead of a limited number of known responses that indicate 'save for environmental health'.

A similar bioanalytical strategy as proposed in the present study for water quality monitoring, is already in use for determination of food quality in Europe. Bioassays are being used for high-throughput screening of large amounts of samples, and chemical analyses are only performed in samples where the bioassay responses indicate a potential risk. An EU working group derived a decision limit for bioanalyses of dioxins, on the basis of a GC/MS confirmation method and the condition that the chance of false negatives should be less than 5%. This bioanalytical procedure is now laid down in EU legislation (European Union, 2012). For other groups of substances (hormones, antibiotics), there are also established methods to regularly apply bioassays in food quality control (e.g., Bovee et al., 2006; Gizzi et al., 2005).

The *in vitro* bioassay panel that is proposed for hazard identification (Table 1), together with bioassays for non-specific toxicity, should be able to distinguish microchemical quality of sites for low or potential risks for adverse ecological health effects. The authors realize that it is 'scientifically impossible' to derive solid and realistic trigger values for bioassays that distinguish between 'good' and 'bad' chemical status, if the identity of compounds that cause the bioassay responses is unknown. Since the identity of the compounds that cause a bioassay effect is unknown, both over- and underestimations of the overall toxic impact of the mixture can be made with the TEQ concept. Moreover, it is hard to predict adverse *in vivo* effects with *in vitro* responses (Escher and Leusch, 2012). Nevertheless, an approach is suggested to make an initial screening for potential environmental risks with *in vivo* as well as *in vitro* bioassay responses. It is again emphasized that we do not claim to make a sharp division between good and bad, but we suggest a toxicity screening to distinguish between low and potential microchemical risks for the environment. Potential risks have to be verified in a second phase risk assessment with a combination of advanced chemical and toxicological tools (Figure 1). The discriminative power of the first phase should be able to indicate potential hazards, but not all of the investigated sites should be classified as being a potential risk. This means that the precautionary principle and the use of high safety factors are not consequently adapted. Instead, this approach tries applied low safety factors to derive safe TEQ. In addition, the design of low risk EBT is based on more realistic environmental estimations, comparison with a species sensitivity distribution and a benchmark with known chemical and biological data (e.g., good ecological status of sites). The trigger values that were developed with this approach are listed in Table 6. The EBTs proposed in this report are most probably not the definite values, since they could be subject to refinement when additional information becomes available.

Jarosova et al. (2014) derived safe environmental concentrations of estrogenic equivalents (EEQ-SSE) in municipal wwtp effluents, based on simplified assumption that only steroid estrogens are responsible for *in vitro* estrogenicity. EEQ-SSE were derived using the estrogenic REP in bioassays, the *in vivo* PNECs of the compounds, and their relative contributions to the overall estrogenicity of wwtp effluents. The EEQ-SSEs for ER-CALUX varied from 0.2 to 0.4 ng EEQ/L for long-term exposure and from 0.6 to 2.0 for short-term exposure. Kunz et al. (2015) proposed to use the annual average environmental quality standard (AA-EQS) of 17-estradiol (E2) of 0.4 ng/L as a trigger value for overall estrogenic activity, among others because using the 0.035 ng/L AA-EQS of ethinyl-estradiol, would overestimate the risks in most cases. The EBT of 0.5 ng EEQ/L we

proposed for ERa CALUX was close to the trigger values proposed by Jarosova and Kunz. Johnson et al. (2007) suggested a PNEC for combined estrogenic activity of 1 ng EEQ/L, but this was based upon an outdated PNEC value for estradiol.

Of course there are several limitations and assumptions connected to the present study that need to be considered and validated in future research. Four assumptions had to be made in the EBT design, regarding i) ratio of 10 used to convert acute to chronic toxicity, ii) estimated duration of chronic toxicity studies, iii) assessment factors to convert concentrations of toxicity endpoints (LOEC, EC50 and LC50) to safe values, and iv) the selection of compounds was restricted to their relative effect potencies (REP) in the bioassay. There are also limitations regarding toxicological data from which the EBTs were derived. Only chemicals with a known REP in the bioassay could be considered due to the toxic equivalents (TEQ) approach. Reliable REP values are essential for a good conversion of substance concentrations to TEQ, but it was not always possible to assess REPs with EC50 data due to cytotoxicity in the bioassay at higher concentrations. The CALUX REPs that were estimated with EC10 values may not be 100% accurate if the slopes of the dose-response curves differ from that of the reference compound.

For several compounds that met the REP requirements it was hard or impossible to find aquatic toxicity data. This resulted in a limited dataset for some of the bioassays considered in the present study (e.g. DR CALUX and GR CALUX). Toxicity studies with antibiotics are mainly focused on invertebrate species, although some data are available for fish. No data, however, could be found for reptiles or mammals and only one study reported acute effects of antibiotics on an amphibian species. Since the EBT values will be used to assess the water quality, all toxicity data had to be water concentrations that indicate a certain effect (PNEC, NOEC, LOEC, EC50 or LC50) to aquatic organisms. Laboratory exposures investigate the toxic effects of single compounds to single species under controlled conditions. Toxic effects of substances in the natural environment can be enhanced or decreased by different physico-chemical conditions, such as pH, temperature and light exposure. This can lead to an under- or over-estimation of the risk connected to the concentrations of chemicals in the environment. In addition, the majority of the studies investigating the toxicity of highly hydrophobic compounds only reported nominal concentrations, as a result of which the toxicity can be underestimated. Therefore, future research should focus the actual concentrations of these compounds causing the reported negative effects.

Despite its limitations and uncertainties, the approach proposed in this study constitutes a better alternative to the current EU WFD monitoring that chemically analyses a limited amount of priority compounds in grab samples. Grab samples are only snapshots of the varying water contamination that does not consider the bioavailability of the compounds, while passive sampling assesses a time-weight average concentration of bioavailable compounds. The highest uncertainty, however, is to analyze only 45 priority compounds in order to assess the overall risk of micropollutants in the water, while the potential impact of more than 100,000 unknown compounds remains unknown. Therefore, reliable alternatives are needed to provide a more realistic hazard identification and risk assessment of the chemical pollution of surface waters. The strategy proposed in this paper represents one of the first attempts to connect bioassays responses with potential negative effects for aquatic population. This hazard assessment approach, combined with chemical analysis, is more reliable and realistic than the current monitoring conducted with chemical analyses only.

Nowadays, it is fundamental to propose better monitoring strategies in order to preserve the quality of freshwater environment, since availability of water supplies and his capacity to sustain human life and economy as we know it is becoming an issue due to the constant increase of human population. As pointed out by Stikker (1998) “the availability of clean water is one of the basic conditions for achieving sustainable development in the 21st century. Sustainable development implies that future generations should have the same opportunities of enjoying a decent quality of life as does the present generation” since “where there is no water, there is no food, no consumer and no business activity”. The introduction of bioassays can lead to a more sustainable water quality monitoring, as they meet the sustainability criteria better than the classical strategies (Gagnon et al., 2007).

Further refinement of EBT derivation should be based upon expert judgment and future validation studies. Together, the two types of triggers (safe TEQ and low risk EBT) should make a distinction between sites with negligible microchemical risks, low risks or potential risks for the ecosystem health. EAWAG Switzerland uses a similar approach with 3 categories: i) good (<safe TEQ), ii) in range of quality criterion (<low risk EBT) or iii) poor (>EBT) (Cornelia Kienle [EAWAG], personal communication). The outcome of the SIMONI model indicates which sites are hot-spots, relevant for additional chemical-toxicological research. Moreover, if specific or reactive activities are above EBT, the model will indicate which class of chemicals may cause the main problem for aquatic organisms. If the information from the SIMONI hazard assessment is combined with the available knowledge of various aspects of the water system (such as influences of other ecological key factors), a tailor-made plan can be designed for further ecological risk assessment. This assessment should be able to identify the main causes of an impaired ecological status, so that the most cost-effective and efficient measures can be taken to improve the water quality. The next steps to make the proposed concept attractive for risk assessors would be to gain experience upon the applicability to case studies and to evaluate its robustness for practical use. Field validation studies with this strategy will be described in the second paper of the “SIMONI as a novel bioanalytical strategy for water quality assessment” series (Van der Oost et al., in progress). Due to its low costs and high relevance, this SIMONI model has the potential to become the first bioanalytical strategy to be applied in regular monitoring of surface water quality. Most Dutch water authorities will start feasibility studies with the SIMONI strategy in 2016.

## 5 CONCLUSIONS

This study aimed to derive EBTs for a selection of bioassays (see Table 7). These trigger values were derived by an extensive review of the available literature on aquatic toxicity of compounds that had a significant response in the bioassays, an SSD analysis on TEQ values and benchmarking with environmental field investigations conducted by Waternet. In only a small percentage of the field samples activities were found above the proposed low-risk effect-based trigger values. However, since these draft EBTs have been derived with some assumptions and simplifications, they may be adjusted when new information becomes available. Nevertheless, if the primary aim of a monitoring program is to assess the chemical water quality, bioassays will be powerful holistic tools to detect situations at risk where additional risk assessment is needed. This project may provide a new standard for the interpretation of bioassay data, and implementation in regular monitoring programs. The alternative monitoring strategy presented in this study has the potential to reduce monitoring costs if advanced chemical analyses only have to be applied at sites where EBTs are exceeded. In addition, costs on expensive measures to improve the water quality can be reduced since the chemical risks can be better assessed with the SIMONI strategy.

**TABLE 7**

*Summary of all safe and low-risk EBTs for the initial selection of in vitro bioassays.*

Activity	Units	Safe EBT	Low risk EBT
Estrogenic	ng EEQ/L	0.0066	0.5
Anti-androgenic	µg F1EQ/L	0.00005	25
Dioxin and dioxin-like	pg TEQ/L	0.4	50
Glucocorticoid	ng DEQ/L	20	100
PPAR $\gamma$ receptor	ng REQ/L	0.00014	10
Toxic PAHs	ng BEQ/L	0.04	150
Oxidative stress	µg CEQ/L	0.000006	10
Pregnane X receptor	µg N1EQ/L	0.000004	3
Aminoglycosides	ng N2EQ/L	300	500
Macrolides & $\beta$ -Lactam	ng PEQ/L	1.8	50
Antibiotics: Sulphonamides	ng SEQ/L	10	100
Tetracyclines	ng OEQ/L	170	250
Quinolones	ng F2EQ/L	5.3	100

# APPENDIX SI-I

Relative effect potencies (REP) of all compounds investigated FOR EBT development in all bioassays

For antibiotics, the REPs were calculated using detection limits of RIKILT WaterScan method, except for \*: RIKILT MeatScan method; and \*\*: NDKT method.

For antibiotics, the REPs were calculated using detection limits of RIKILT WaterScan method, except for \*: RIKILT MeatScan method; and \*\*: NDKT method.

## FOUNDATION FOR APPLIED WATER RESEARCH STOWA

---

STOWA (Acronym for Foundation for Applied Water Research) is the knowledge centre of the regional water managers (mostly the Dutch Water Authorities) in the Netherlands. Its mission is to develop, collect, distribute and implement applied knowledge, which the water managers need in order to adequately carry out the tasks that their work supports. This expertise can cover applied technical, scientific, administrative-legal or social science fields.

STOWA is a highly demand-driven operation. We carefully take stock of the knowledge requirements of the Water Authorities and ensure that these are placed with the correct knowledge providers. The initiative for this mainly lies with the users of this knowledge, the water managers, but sometimes also with knowledge institutes and business and industry. This two-way flow of knowledge promotes modernisation and innovation.

Demand-driven operation also means that we are constantly looking for the 'knowledge requirements of tomorrow' – requirements that we dearly want to put on the agenda before they become an issue – in order to ensure that we are optimally prepared for the future.

We ease the burden of the water managers by assuming the tasks of placing the invitation to tender and supervising the joint knowledge projects. STOWA ensures that water managers remain linked to these projects and also retain 'ownership' of them. In this way, we make sure that the correct knowledge requirements are met. The projects are supervised by committees, which also comprise regional water managers. The broad research lines are spread out per field of practice and accounted for by special programme committees. The water managers also have representatives on these committees.

STOWA is not only a link between the users of knowledge and knowledge providers, but also between the regional water managers. The collaboration of the water managers within STOWA ensures they are jointly responsible for the programming, that they set the course, that several Water Authorities are involved with one and the same project and that the results quickly benefit all Water Boards.

### MISSION STATEMENT:

STOWA's fundamental principles are set out in our mission: Defining the knowledge needs in the field of water management and developing, collecting, making available, sharing, strengthening and implementing the required knowledge or arranging for this together with regional water managers.

stowa
