**Abstract.** Understanding the processes that affect the triple oxygen isotope composition of atmospheric  $\text{CO}_2$  during gas exchange can help constrain the interaction and fluxes between the atmosphere and the biosphere. We conducted leaf cuvette experiments under controlled conditions using three plant species. The experiments were conducted at two different light intensities and using  $\text{CO}_2$  with different  $\Delta^{17}\text{O}$ . We directly quantify the effect of photosynthesis on  $\Delta^{17}\text{O}$  of atmospheric  $\text{CO}_2$  for the first time. Our results demonstrate the established theory for  $\delta^{18}\text{O}$  is applicable to  $\Delta^{17}\text{O}(\text{CO}_2)$  at leaf level, and we confirm that the following two key factors determine the effect of photosynthetic gas exchange on the  $\Delta^{17}\text{O}$  of atmospheric  $\text{CO}_2$ . The relative difference between  $\Delta^{17}\text{O}$  of the  $\text{CO}_2$  entering the leaf and the  $\text{CO}_2$  in equilibrium with leaf water and the back-diffusion flux of  $\text{CO}_2$  from the leaf to the atmosphere, which can be quantified by the  $c_m/c_a$  ratio, where  $c_a$  is the  $\text{CO}_2$  mole fraction in the surrounding air and  $c_m$  is the one at the site of oxygen isotope exchange between  $\text{CO}_2$  and  $\text{H}_2\text{O}$ . At low  $c_m/c_a$  ratios the discrimination is governed mainly by diffusion into the leaf, and at high  $c_m/c_a$  ratios it is governed by back-diffusion of  $\text{CO}_2$  that has equilibrated with the leaf water. Plants with a higher  $c_m/c_a$  ratio modify the  $\Delta^{17}\text{O}$  of atmospheric  $\text{CO}_2$  more strongly than plants with a lower  $c_m/c_a$  ratio. Based on the leaf cuvette experiments, the global value for discrimination against  $\Delta^{17}\text{O}$  of atmospheric  $\text{CO}_2$  during photosynthetic gas exchange is estimated to be  $-0.57 \pm 0.14\text{‰}$  using  $c_m/c_a$  values of 0.3 and 0.7 for  $\text{C}_4$  and  $\text{C}_3$  plants, respectively. The main uncertainties in this global estimate arise from variation in  $c_m/c_a$  ratios among plants and growth conditions.

## 1 Introduction

Stable isotope measurements of  $\text{CO}_2$  provide important information about the magnitude of the  $\text{CO}_2$  fluxes between atmosphere and biosphere, which are the largest components of the global carbon cycle (Farquhar et al., 1989, 1993; Ciais et al., 1997a, b; Flanagan and Ehleringer, 1998; Yakir and Sternberg, 2000; Gillon and Yakir, 2001; Cuntz et al., 2003a, b). A better understanding of the terrestrial carbon cycle is essential for predicting future climate and atmospheric  $\text{CO}_2$  mole fractions (Booth et al., 2012). Gross primary productivity (GPP), the total carbon dioxide uptake by vegetation during photosynthesis, can only be determined indirectly and remains poorly constrained (Cuntz, 2011; Welp et al., 2011). For example, Beer et al. (2010) estimated global GPP to be  $102\text{--}135 \text{ PgC yr}^{-1}$  (85 % confidence interval, CI) using machine learning techniques by extrapolating from a database of eddy covariance measurements of  $\text{CO}_2$ . This estimate has since then been widely used as target for terrestrial vegetation models (Sitch et al., 2015) and replicated based on cross-consistency checks with atmospheric inversions, sun-induced fluorescence (SIF), and global vegetation models (Jung et al., 2020). As an alternative, Welp et al. (2011) estimated global GPP to be  $150\text{--}175 \text{ PgC yr}^{-1}$  using variations in  $\delta^{18}\text{O}$  of atmospheric  $\text{CO}_2$  after the 1997/98 El Niño event; see Eq. (1) for definition of the  $\delta$  value.

The concept behind the latter study was that atmospheric  $\text{CO}_2$  exchanges oxygen isotopes with leaf and soil water, and this isotope exchange mostly determines the observed variations in  $\delta^{18}\text{O}$  of  $\text{CO}_2$  (Francey and Tans, 1987; Yakir, 1998).

Following the 97/98 El Niño–Southern Oscillation (ENSO) event, the anomalous  $\delta^{18}\text{O}$  signature imposed on tropical leaf and soil waters was transferred to atmospheric  $\text{CO}_2$ , before slowly disappearing as a function of the lifetime of atmospheric  $\text{CO}_2$ . This in turn is governed by the land vegetation uptake of  $\text{CO}_2$  during photosynthesis, as well as soil invasion of  $\text{CO}_2$  (Miller et al., 1999; Wingate et al., 2009). For the photosynthesis term, the equilibration of  $\text{CO}_2$  with water is an uncertain parameter in this calculation, partly because the  $\delta^{18}\text{O}$  of water at the site of isotope exchange in the leaf is not well defined. Importantly, a significant  $\delta^{18}\text{O}$  variation can occur in leaves due to the preferential evaporation of  $\text{H}_2^{16}\text{O}$  relative to  $\text{H}_2^{18}\text{O}$  (Gan et al., 2002, 2003; Farquhar and Gan, 2003; Cernusak et al., 2016), which induces a considerable uncertainty in estimating  $\delta^{18}\text{O}$  of  $\text{CO}_2$ . Similar considerations for the transfer of the  $\delta^{18}\text{O}$  signature of precipitation into the soils, and then up through the roots, stems, and leaves makes  $^{18}\text{O}$  of  $\text{CO}_2$  a challenging measurement to interpret (Peylin et al., 1999; Cuntz et al., 2003a, b).

Classical isotope theory posits that oxygen isotope distributions are modified in a mass-dependent way. This means that the  $^{17}\text{O}/^{16}\text{O}$  ratio changes by approximately half of the corresponding change in  $^{18}\text{O}/^{16}\text{O}$  (Eq. 2), and it applies to the processes involved in gas exchange between atmosphere and plants. However, in 1983 Thiemens and co-workers (Heidenreich and Thiemens, 1983, 1986; Thiemens and Heidenreich, 1983) reported a deviation from mass-dependent isotope fractionation in ozone ( $\text{O}_3$ ) formation called mass-independent isotope fractionation ( $\Delta^{17}\text{O}$ , Eq. 3). In the stratosphere, the  $\Delta^{17}\text{O}$  of  $\text{O}_3$  is transferred to  $\text{CO}_2$  via isotope exchange of  $\text{CO}_2$  with  $\text{O}(^1\text{D})$  produced from  $\text{O}_3$  photolysis (Yung et al., 1991, 1997; Shaheen et al., 2007), which results in a large amount of  $\Delta^{17}\text{O}$  in stratospheric  $\text{CO}_2$  (Thiemens et al., 1991, 1995; Lyons, 2001; Lämmerzahl et al., 2002; Thiemens, 2006; Kawagucci et al., 2008; Wiegel et al., 2013).

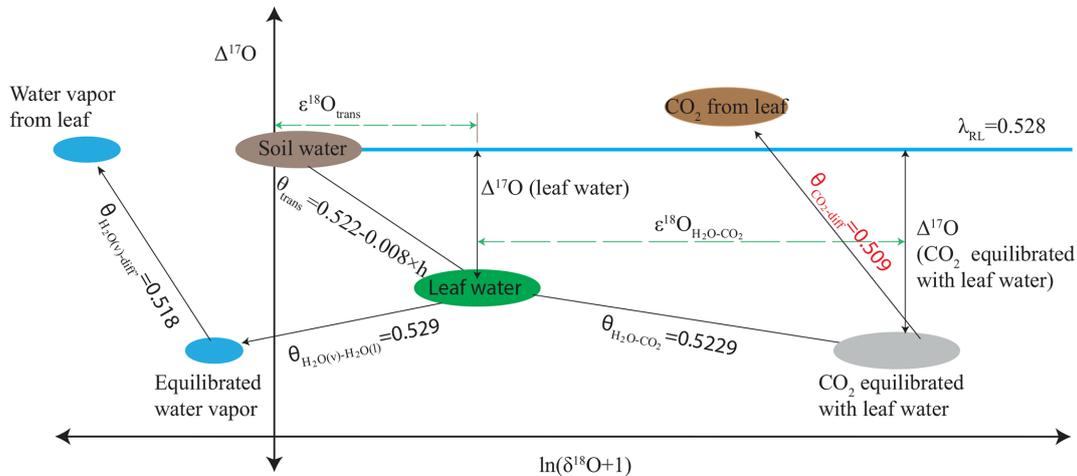

Once  $\Delta^{17}\text{O}$  has been created in stratospheric  $\text{CO}_2$ , the only process that modify its signal is isotope exchange with leaf water, soil water and ocean water at the Earth's surface, after  $\text{CO}_2$  has reentered the troposphere (Boering, 2004; Thiemens et al., 2014; Liang and Mahata, 2015; Hofmann et al., 2017). Isotope exchange with leaf water is more efficient relative to ocean water due to the presence of the enzyme carbonic anhydrase (CA), which effectively catalyzes the conversion of  $\text{CO}_2$  and  $\text{H}_2\text{O}$  to  $\text{HCO}_3^-$  and  $\text{H}^+$  and vice versa (Francey and Tans, 1987; Friedli et al., 1987; Badger and Price, 1994; Gillon and Yakir, 2001). The isotope exchange in the atmosphere is negligible due to lower liquid water content, lower residence time, and the absence of carbonic anhydrase (Mills and Urey, 1940; Miller et al., 1971; Johnson, 1982; Silverman, 1982; Francey and Tans, 1987).

$\Delta^{17}\text{O}$  of  $\text{CO}_2$  has been suggested as an additional independent tracer for constraining global GPP (Hoag et al., 2005; Thiemens et al., 2013; Hofmann et al., 2017; Liang et al., 2017b; Koren et al., 2019) because the processes involved

in plant–atmosphere gas exchange are all mass dependent. Therefore,  $\Delta^{17}\text{O}$  at the  $\text{CO}_2$ – $\text{H}_2\text{O}$  exchange site in the leaf will vary much less than  $\delta^{18}\text{O}$ . Nevertheless, mass-dependent isotope fractionation processes with slightly different three-isotope fractionation slopes are involved, which have been precisely established in the past years. Figure 1 shows how the different processes affect  $\Delta^{17}\text{O}$  of the  $\text{H}_2\text{O}$  and  $\text{CO}_2$  reservoirs involved. The triple isotope slope of oxygen in meteoric waters is taken as reference slope,  $\lambda_{\text{Ref}} = 0.528$  (Meijer and Li, 1998; Barkan and Luz, 2007; Landais et al., 2008; Luz and Barkan, 2010; Uemura et al., 2010), and we assume that soil water is similar to meteoric water. Due to transpiration and diffusion in the leaf,  $\Delta^{17}\text{O}$  of leaf water gets modified following a humidity-dependent three-isotope slope  $\theta_{\text{trans}} = 0.522 - 0.008 \times h$  (Landais et al., 2006). Exchange of oxygen isotopes between leaf water and  $\text{CO}_2$  follows  $\theta_{\text{CO}_2\text{--H}_2\text{O}} = 0.5229$  (Barkan and Luz, 2012), which determines the  $\Delta^{17}\text{O}$  of  $\text{CO}_2$  inside the leaf at the  $\text{CO}_2$ – $\text{H}_2\text{O}$  exchange site. Finally, the  $\Delta^{17}\text{O}$  of the  $\text{CO}_2$  is modified when  $\text{CO}_2$  diffuses into and out of the leaf with  $\lambda_{\text{diff}} = 0.509$  (Young et al., 2002).

In the first box model study of Hoag et al. (2005), the small deviations in  $\Delta^{17}\text{O}$  of  $\text{CO}_2$  due to differences in three-isotope slopes were neglected and exchange with water was assumed to reset  $\Delta^{17}\text{O}$  to 0. Hofmann et al. (2017) included the different isotope effects shown in Fig. 1 in their box model. Koren et al. (2019) incorporated all the physicochemical processes affecting  $\Delta^{17}\text{O}$  of  $\text{CO}_2$  in a 3D atmospheric model and investigated the spatiotemporal variability of  $\Delta^{17}\text{O}$  and its use as tracer for GPP. Using these and other similar models, numerous measurements of  $\Delta^{17}\text{O}$  in atmospheric  $\text{CO}_2$  from different locations have been performed and used to estimate GPP (Liang et al., 2006; Barkan and Luz, 2012; Thiemens et al., 2014; Liang and Mahata, 2015; Laskar et al., 2016; Hofmann et al., 2017). The three-isotope slopes of the processes involved in the gas exchange (Fig. 1) have been precisely determined in idealized experiments. In the advanced models mentioned above it is assumed that when all the pieces are put together they result in a realistic overall modification of  $\Delta^{17}\text{O}$  of  $\text{CO}_2$  in the atmosphere surrounding the leaf. However, this has not been confirmed by measurements previously.

In this study we report the effect of photosynthesis on  $\Delta^{17}\text{O}$  of  $\text{CO}_2$  in the surrounding air at the leaf scale. We measured  $\Delta^{17}\text{O}$  of  $\text{CO}_2$  entering and leaving a leaf cuvette to calculate the isotopic fractionation associated with photosynthesis for three species that are representative for three different biomes. The fast-growing annual herbaceous  $\text{C}_3$  species *Helianthus annuus* (sunflower) has a high photosynthetic capacity ( $A_n$ ) and high stomatal conductance ( $g_s$ ) and is representative for temperate and tropical crops (Fredeen et al., 1991). The slower-growing perennial evergreen  $\text{C}_3$  species *Hedera hibernica* (ivy) is representative of forests and other woody vegetation and stress-subjected habitats (Pons et al., 2009). The fast-growing, agronomically im-

**Figure 1.** Schematic for mass-dependent isotope fractionation process that affects the  $\Delta^{17}\text{O}$  of the  $\text{CO}_2$  and  $\text{H}_2\text{O}$  during the photosynthetic gas exchange (not to scale). The triple oxygen isotope relationships for the individual isotope fractionation processes (both kinetic and equilibrium fractionation) are assigned with  $\theta$ .  $\theta_{\text{trans}} = 0.522 - 0.008 \times h$ , where  $h$  is relative humidity (Landais et al., 2006). In this study the humidity is 75 %,  $\theta_{\text{trans}} = 0.516$ ,  $\theta_{\text{CO}_2-\text{H}_2\text{O}}$  (Barkan and Luz, 2012),  $\theta_{\text{CO}_2-\text{diff}}$  (Young et al., 2002),  $\theta_{\text{H}_2\text{O}(v)-\text{H}_2\text{O}(l)}$  (Barkan and Luz, 2005), and  $\theta_{\text{H}_2\text{O}(v)-\text{diff}}$  (Barkan and Luz, 2007), where  $v$  and  $l$  are vapor and liquid water, respectively.  $\epsilon^{18}\text{O}$  is enrichment or depletion in  $^{18}\text{O}$  isotope composition due to the corresponding isotope fractionation process, and diff and trans stand for diffusion and transpiration, respectively.

portant crop *Zea mays* (maize) is an herbaceous annual  $\text{C}_4$  species with a high  $A_n$  and a low  $g_s$ , typical for savanna type vegetation (van der Weijde et al., 2013). The mole fraction of  $\text{CO}_2$  at the  $\text{CO}_2-\text{H}_2\text{O}$  exchange site ( $c_m$ ) is an important parameter to determine the effect of photosynthesis on  $\Delta^{17}\text{O}$  of  $\text{CO}_2$ . In  $\text{C}_3$  plants, the  $\text{CO}_2-\text{H}_2\text{O}$  exchange can occur anywhere between the plasma membrane and the chloroplast since the catalyzing enzyme CA has been found in the chloroplast, cytosol, mitochondria, and plasma membrane (Fabre et al., 2007; DiMario et al., 2016). For  $\text{C}_4$  plants, CA is mainly found in the cytosol, and the  $\text{CO}_2-\text{H}_2\text{O}$  exchange occurs there (Badger and Price, 1994). In our experiments, sunflower and ivy are used to cover the wide  $c_m/c_a$  ratio range among  $\text{C}_3$  plants and maize represents the  $c_m/c_a$  ratio for the  $\text{C}_4$  plants. Using our results from the leaf-scale experiments, we estimated the effect of terrestrial vegetation on  $\Delta^{17}\text{O}$  of  $\text{CO}_2$  in the global atmosphere.

## 2 Theory

### 2.1 Notation and definition of $\delta$ values

Isotopic composition is expressed as the deviation of the heavy-to-light isotope ratio in a sample relative to a reference ratio and is denoted as  $\delta$ , expressed in per mill (‰). In the case of oxygen isotopes, the isotope ratios are  $^{18}\text{R} = [^{18}\text{O}]/[^{16}\text{O}]$  and  $^{17}\text{R} = [^{17}\text{O}]/[^{16}\text{O}]$  and the reference material is Vienna Standard Mean Ocean Water (VSMOW):

$$\delta^n\text{O} = \frac{^n\text{R}_{\text{sample}}}{^n\text{R}_{\text{VSMOW}}} - 1, \quad n \text{ refers to } 17 \text{ or } 18. \quad (1)$$

For most processes, isotope fractionation depends on mass, and therefore the fractionation against  $^{17}\text{O}$  is approximately half of the fractionation against  $^{18}\text{O}$  (Eq. 3).

$$\ln(\delta^{17}\text{O} + 1) = \lambda \times \ln(\delta^{18}\text{O} + 1) \quad (2)$$

The mass-dependent isotope fractionation factor  $\lambda$  ranges from 0.5 to 0.5305 for different molecules and processes (Matsuhisa et al., 1978; Thiemens, 1999; Young et al., 2002; Cao and Liu, 2011).  $\Delta^{17}\text{O}$  is used to quantify the degree of deviation from Eq. (2) (see Eq. 3). Note that  $\Delta^{17}\text{O}$  changes not only by mass-independent isotope fractionation processes but also by mass-dependent isotope fractionation processes with a different  $\lambda$  value from the one used in the definition of  $\Delta^{17}\text{O}$  (Barkan and Luz, 2005, 2011; Landais et al., 2006, 2008; Luz and Barkan, 2010; Pack and Herwartz, 2014).

$$\Delta^{17}\text{O} = \ln(\delta^{17}\text{O} + 1) - \lambda \times \ln(\delta^{18}\text{O} + 1) \quad (3)$$

The choice of  $\lambda$  is in principle arbitrary, and in this study we use  $\lambda = 0.528$ , which was established for meteoric waters (Meijer and Li, 1998; Landais et al., 2008; Brand et al., 2010; Luz and Barkan, 2010; Barkan and Luz, 2012; Sharp et al., 2018). Equation (3) can be linearized to  $\Delta^{17}\text{O} = \delta^{17}\text{O} - \lambda \times \delta^{18}\text{O}$  (Miller, 2002), but this approximation causes an error that increases with  $\delta^{18}\text{O}$  (Miller, 2002; Bao et al., 2016).

### 2.2 Discrimination against $\Delta^{17}\text{O}$ of $\text{CO}_2$

The overall isotope fractionation associated with the photosynthesis of  $\text{CO}_2$  is commonly quantified using the term dis-

crimination, as described in Farquhar and Richards (1984), Farquhar et al. (1989), and Farquhar and Lloyd (1993). We use the symbol  $\Delta_A$  for discrimination due to assimilation in this paper since the commonly used  $\Delta$  is already used for the definition of  $\Delta^{17}\text{O}$  (see Eq. 3).  $\Delta_A$  quantifies the enrichment or depletion of carbon and oxygen isotopes of  $\text{CO}_2$  in the surrounding atmosphere relative to the  $\text{CO}_2$  that is assimilated (Farquhar and Richards, 1984). It can be calculated from the isotopic composition of the  $\text{CO}_2$  entering and leaving the leaf cuvette (Evans et al., 1986; Gillon and Yakir, 2000a; Barbour et al., 2016) as follows:

$$\begin{aligned} \Delta_A^n \text{O}_{\text{obs}} &= \frac{nR_a}{nR_A} - 1 = \frac{n\text{O}_a - \delta^n \text{O}_A}{1 + \delta^n \text{O}_A} \\ &= \frac{\zeta \times (\delta^n \text{O}_a - \delta^n \text{O}_e)}{1 + \delta^n \text{O}_a - \zeta \times (\delta^n \text{O}_a - \delta^n \text{O}_e)}, \end{aligned} \quad (4)$$

where the indices  $e$ ,  $a$  and  $A$  refer to  $\text{CO}_2$  entering and leaving the cuvette and being assimilated, respectively.  $\zeta = \frac{c_e}{c_e - c_a}$ , where  $c_e$  and  $c_a$  are the mole fractions of  $\text{CO}_2$  entering and leaving the cuvette. For quantifying the effect of photosynthesis on  $\Delta^{17}\text{O}$  in our experiments, the  $\Delta_A \Delta^{17}\text{O}$  is calculated from  $\Delta_A^{17}\text{O}$  and  $\Delta_A^{18}\text{O}$  using the three-isotope slope  $\lambda_{\text{RL}} = 0.528$ , similar to Eq. (3). In previous studies slightly different formulations have been used to define the effect of photosynthesis on  $\Delta^{17}\text{O}$ , and a comparison of the different definitions is provided in the Supplement (Eqs. S37–S40).

It is important to note that when the logarithmic definition of  $\Delta^{17}\text{O}$  or  $\Delta_A \Delta^{17}\text{O}$  is used, values are not additive (Kaiser et al., 2004). In linear calculations, the error gets larger when the relative difference in  $\delta^{18}\text{O}$  between the two  $\text{CO}_2$  gases increases regardless of the  $\Delta^{17}\text{O}$  of the individual  $\text{CO}_2$  gases (Fig. S1 in the Supplement). Therefore,  $\Delta_A \Delta^{17}\text{O}$  values have to be calculated from the individual  $\Delta_A^{17}\text{O}$  and  $\Delta_A^{18}\text{O}$  values and not by linear combinations of the  $\Delta^{17}\text{O}$  of air entering and leaving a plant chamber.

### 3 Materials and methods

#### 3.1 Plant material and growth conditions

Sunflower (*Helianthus annuus* L. cv “sunny”) was grown from seeds in 0.6 L pots with potting soil (Primasta, the Netherlands) for about 4 weeks. All leaves appearing above the first leaf pair were removed to avoid shading. Established juvenile ivy (*Hedera hibernica* L.) plants were pruned and planted in 6 L pots for 6 weeks. Ivy leaves that had developed and matured were used for the experiments. Maize (*Z. mays* L. cv “saccharate”) was grown from seed in 1.6 L pots for at least 7 weeks. For maize, the fourth or higher leaf number was used for the experiments when it was mature. A section of the leaf at about one-third from the tip was inserted into the leaf cuvette. They were placed on a sub-irrigation system that provided water during the growth period in a controlled-environment growth chamber, with an

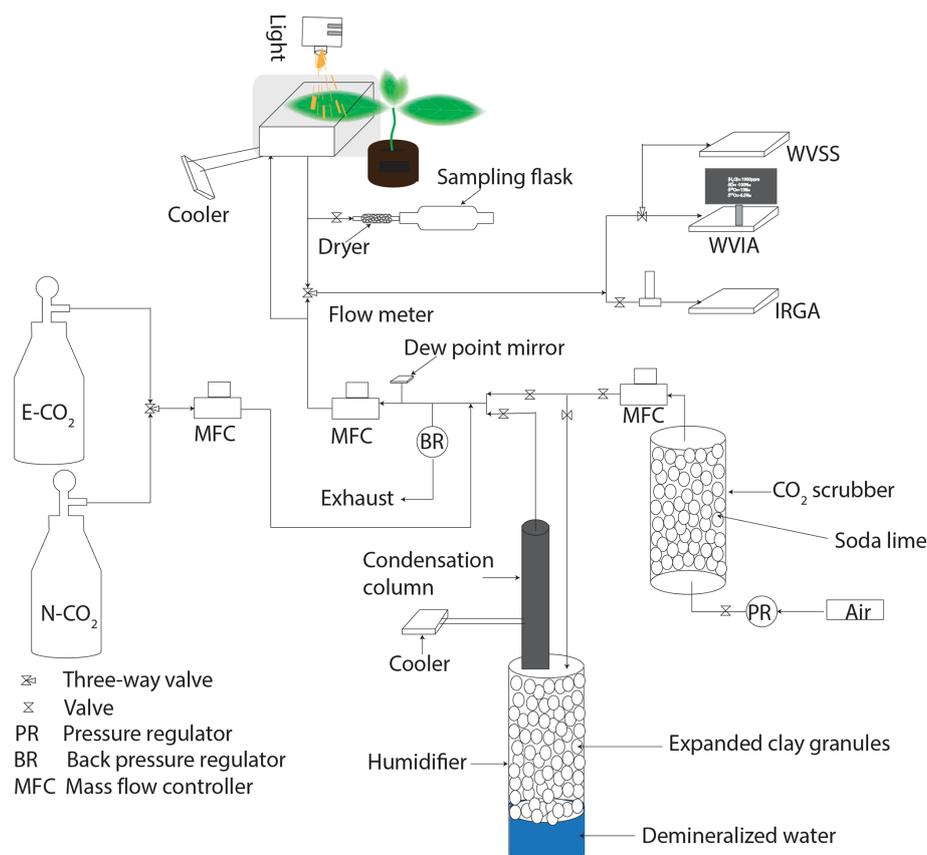

air temperature of 20 °C, relative humidity of 70 %, and  $\text{CO}_2$  mole fraction of about 400 ppm. The photosynthetic photon flux density (PPFD) was about  $300 \mu\text{mol m}^{-2} \text{s}^{-1}$  during a daily photoperiod of 16 h measured with a PPFD meter (Li-Cor LI-250A, Li-Cor Inc, NE, USA).

#### 3.2 Gas exchange experiments

Gas exchange experiments were performed in an open system where a controlled flow of air enters and leaves the leaf cuvette, similar to the setup used by Pons and Welschen (2002). A schematic for the gas exchange experimental setup is shown in Fig. 2. The leaf cuvette had dimensions of  $7 \times 7 \times 7 \text{ cm}^3$  ( $l \times w \times h$ ) and the top part of the cuvette was transparent. The temperature of the leaf was measured with a K type thermocouple. The leaf chamber temperature was controlled by a temperature-controlled water bath kept at 20 °C (Tamson TLC 3, The Netherlands). A halogen lamp (Pradovit 253, Ernst Leitz Wetzlar GmbH, Germany) in a slide projector was used as a light source. Infrared was excluded by reflection from a cold mirror. The light intensity was varied with spectrally neutral filters (Pradovit 253, Ernst Leitz Wetzlar GmbH, Germany).

The  $\text{CO}_2$  mole fraction of the incoming and outgoing air was measured with an infrared gas analyzer (IRGA, model LI-6262, Li-Cor Inc., NE, USA). The isotopic composition and mole fraction of the incoming and outgoing water vapor were measured with a triple water vapor isotope analyzer (WVIA, model 911-0034, Los Gatos Research, USA). Compressed air (ambient outside air without drying) was passed through soda lime to scrub the  $\text{CO}_2$ . The  $\text{CO}_2$ -free air could be humidified depending on the experiment conditions (see Fig. 2). The humidity of the inlet air was monitored continuously with a dew point meter (HYGRO-M1, General Eastern, Watertown, MA, USA). Pure  $\text{CO}_2$  (either normal  $\text{CO}_2$  or isotopically enriched  $\text{CO}_2$ ) was mixed with the incoming air to produce a  $\text{CO}_2$  mole fraction of 500 ppm. The isotopically enriched  $\text{CO}_2$  was prepared by photochemical isotope exchange between  $\text{CO}_2$  and  $\text{O}_2$  under UV irradiation (Adnew et al., 2019).

An attached leaf or part of it was inserted into the cuvette, the composition of the inlet air was measured, and both IRGA and WVIA were switched to measure the outlet air. Based on the  $\text{CO}_2$  mole fraction of the outgoing air the flow rate of the incoming air to the cuvette was adjusted to establish a drawdown of 100 ppm  $\text{CO}_2$  due to photosynthesis in the plant chamber. The water vapor content entering the cuvette was adjusted depending on the transpiration rate relative to  $\text{CO}_2$  uptake to avoid condensation (Fig. 2). The outgoing air was measured continuously until a steady state was reached for  $\text{CO}_2$  and  $\text{H}_2\text{O}$  mole fractions and  $\delta\text{D}$  and  $\delta^{18}\text{O}$  of the water vapor. After a steady state was established, the air was directed to the sampling flask while the IRGA and WVIA were switched back to measure the inlet air. The air

**Figure 2.** Schematic diagram of the leaf cuvette experimental setup. IRGA stands for the infrared gas analyzer, WVSS is the water vapor standard source, WVIA is the water vapor isotope analyzer, N- $\text{CO}_2$  is normal  $\text{CO}_2$ , and E- $\text{CO}_2$  is  $^{17}\text{O}$ -enriched  $\text{CO}_2$ .

passed through a  $\text{Mg}(\text{ClO}_4)_2$  dryer before entering the sampling flask.

After sampling, the leaf area inside the cuvette was measured with a LI-3100C area meter (Li-Cor Inc., USA). Immediately afterward, the leaf was placed in a leak-tight 9 mL glass vial and kept in a freezer at  $-20^\circ\text{C}$  until leaf water extraction.

### 3.3 Calibration of the water vapor isotope analyzer (WVIA) and leaf water analysis

The WVIA was calibrated using five water standards provided by IAEA (Wassenaar et al., 2018) for both  $\delta^{18}\text{O}$  and  $\delta\text{D}$  (Fig. S2). We did not calibrate the WVIA for  $\delta^{17}\text{O}$ , so the  $\delta^{17}\text{O}$  data are not used in the quantitative evaluation. The isotopic composition of the water standards ranged from  $-50.93\text{‰}$  to  $3.64\text{‰}$  and  $-396.98\text{‰}$  to  $25.44\text{‰}$  for  $\delta^{18}\text{O}$  and  $\delta\text{D}$ , respectively. The detailed characterization and calibration of the WVIA is provided in the Supplement (Figs. S2 to S4).

Leaf water was extracted by cryogenic vacuum distillation for 4 h at  $60^\circ\text{C}$  following a well-established procedure as shown in Fig. S5 (Wang and Yakir, 2000; Landais et al., 2006; West et al., 2006). Details are provided in the

Supplement. The  $\delta^{17}\text{O}$  and  $\delta^{18}\text{O}$  of leaf water were determined at the Laboratoire des Sciences du Climat et de l'Environnement laboratory using a fluorination technique as described in Barkan and Luz (2005) and Landais et al. (2006, 2008).

### 3.4 Carbon dioxide extraction and isotope analysis

$\text{CO}_2$  was extracted from the air samples in a system made from electropolished stainless steel (Fig. S6). Our system used four commercial traps (MassTech, Bremen, Germany). The first two traps were operated at dry ice temperature ( $-78^\circ\text{C}$ ) to remove moisture and some organics. The other two traps were operated at liquid nitrogen temperature ( $-196^\circ\text{C}$ ) to trap  $\text{CO}_2$ . The flow rate during extraction was  $55\text{ mL min}^{-1}$  controlled by a mass flow controller (Brooks Instruments, the Netherlands). The reproducibility of the extraction system was  $0.030\text{‰}$  for  $\delta^{18}\text{O}$  and  $0.007\text{‰}$  for  $\delta^{13}\text{C}$  determined on 14 extractions ( $1\sigma$  standard deviation, Table S1 in the Supplement).

The  $\Delta^{17}\text{O}$  of  $\text{CO}_2$  was determined using the  $\text{CO}_2\text{--O}_2$  exchange method (Mahata et al., 2013; Barkan et al., 2015; Adnew et al., 2019). The  $\text{CO}_2\text{--O}_2$  exchange system used at Utrecht University is described in Adnew et al. (2019). In

short, equal amounts of  $\text{CO}_2$  and  $\text{O}_2$  were mixed in a quartz reactor containing a platinum sponge catalyst and heated at  $750^\circ\text{C}$  for 2 h. After isotope equilibration, the  $\text{CO}_2$  was trapped at liquid nitrogen temperature, while the  $\text{O}_2$  was collected with 1 pellet of a  $5\text{\AA}$  molecular sieve (1.6 mm, Sigma Aldrich, USA) at liquid nitrogen temperature. The isotopic composition of the isotopically equilibrated  $\text{O}_2$  was measured with a Delta<sup>Plus</sup>XL isotope ratio mass spectrometer in dual-inlet mode with reference to a pure  $\text{O}_2$  calibration gas that has been assigned values of  $\delta^{17}\text{O} = 9.254\text{‰}$  and  $\delta^{18}\text{O} = 18.542\text{‰}$  by Eugeni Barkan at the Hebrew University of Jerusalem. The reproducibility of the  $\Delta^{17}\text{O}$  measurement was better than  $0.01\text{‰}$  (Table S1).

### 3.5 Leaf cuvette model

We used a simple leaf cuvette model to evaluate the dependence of  $\Delta_A\Delta^{17}\text{O}$  on key parameters. In this model, the leaf is partitioned into three different compartments: the intercellular air space, the mesophyll cell, and the chloroplast. In the leaf cuvette model, we used a 100 ppm down-draw of  $\text{CO}_2$ , similar to the leaf exchange experiments, i.e., the  $\text{CO}_2$  mole fraction decreases from 500 ppm in the entering air ( $c_e$ ) to 400 ppm in the outgoing air ( $c_o$ ), which is identical to the air surrounding the leaf ( $c_a$ ) as a result of thorough mixing in the cuvette. The assimilation rate is set to  $20.0\ \mu\text{mol m}^{-2}\ \text{s}^{-1}$ . The leaf area and flow rate of air are set to  $30\ \text{cm}^2$  and  $0.7\ \text{L min}^{-1}$ , respectively. The isotope composition of leaf water at the site where the  $\text{H}_2\text{O}-\text{CO}_2$  exchange occurs is  $\delta^{17}\text{O} = 5.39\text{‰}$  and  $\delta^{18}\text{O} = 10.648\text{‰}$ , which is the mean of the measured  $\delta^{17}\text{O}$  and  $\delta^{18}\text{O}$  values of bulk leaf water in our experiments. The leaf water temperature is set to  $22^\circ\text{C}$  (similar to the experiment). In the model, the  $\delta^{18}\text{O}$  of the  $\text{CO}_2$  entering the cuvette is set to  $30.47\text{‰}$  for all the simulations, as in the normal  $\text{CO}_2$  experiments, but the assigned  $\Delta^{17}\text{O}$  values range from  $-0.5\text{‰}$  to  $0.5\text{‰}$ , which encompasses both the stratospheric intrusion and combustion components. The corresponding  $\delta^{17}\text{O}$  of the  $\text{CO}_2$  entering the cuvette is calculated from the assigned  $\delta^{18}\text{O}$  value ( $30.47\text{‰}$ ) and  $\Delta^{17}\text{O}$  values ( $-0.5\text{‰}$  to  $0.5\text{‰}$ ). For the calculations with this model, we assumed an infinite boundary layer conductance. The leaf cuvette model is illustrated in the Supplement (Fig. S7), and the detailed code and description is available at [https://git.wur.nl/leaf\\_model](https://git.wur.nl/leaf_model) (last access: 23 March 2020, Koren et al., 2020).

## 4 Results

### 4.1 Gas exchange parameters

Table 1 summarizes the isotopic composition and mole fraction of the  $\text{CO}_2$  used in this study for sunflower, ivy and maize. The  $\Delta^{17}\text{O}$  of  $\text{CO}_2$  used in this study varies from  $-0.215\text{‰}$  to  $0.44\text{‰}$ , while the  $\delta^{18}\text{O}$  value is close to  $30\text{‰}$  for all the experiments. For all the experiments, the mole

fraction of  $\text{CO}_2$  entering the leaf ( $c_a$ ) is 400 ppm, whereas the mole fraction of the  $\text{CO}_2$  in the intercellular air space ( $c_i$ ), at the  $\text{CO}_2-\text{H}_2\text{O}$  exchange site ( $c_m$ ), and in the chloroplast ( $c_c$ ) varies depending on the assimilation rate and metabolism type of the plants. Estimating the mesophyll conductance is described in the companion paper. A detailed description for estimating  $c_m$  and  $c_c$  is provided in the Supplement. A list of variables and parameters used in this study are summarized in Table 2.

### 4.2 Discrimination against $^{18}\text{O}$ of $\text{CO}_2$

Figure 3a shows discrimination against  $^{18}\text{O}$  associated with photosynthesis ( $\Delta_A^{18}\text{O}$ ) for sunflower, ivy, and maize as a function of the  $c_m/c_a$  ratio.  $\Delta_A^{18}\text{O}$  varies with  $c_m/c_a$ , as found in previous studies (Gillon and Yakir, 2000a; Barbour et al., 2016). For sunflower, we observe  $\Delta_A^{18}\text{O}$  values between  $29\text{‰}$  and  $64\text{‰}$  for  $c_m/c_a$  between 0.54 and 0.86. Ivy shows relatively little variation in  $\Delta_A^{18}\text{O}$  around a mean of  $22\text{‰}$  for  $c_m/c_a$  between 0.48 and 0.58. For maize,  $\Delta_A^{18}\text{O}$  is lower than for the  $\text{C}_3$  plants measured in this study, with values between  $10\text{‰}$  and  $20\text{‰}$  for  $c_m/c_a$  between 0.15 and 0.37.

For sunflower, changing the irradiance from  $300\ \mu\text{mol m}^{-2}\ \text{s}^{-1}$  (low light, hereafter LL) to  $1200\ \mu\text{mol m}^{-2}\ \text{s}^{-1}$  (high light, hereafter HL) leads to a clear decrease in  $\Delta_A^{18}\text{O}$  (average  $22\text{‰}$ ). For maize, the  $\Delta_A^{18}\text{O}$  change is only  $4.4\text{‰}$  on average. For ivy, changing the light intensity does not significantly change the observed  $\Delta_A^{18}\text{O}$ . The solid lines in Fig. 3a show the results of leaf cuvette model calculations, where the dependence of  $\Delta_A^{18}\text{O}$  on  $c_m/c_a$  is explored for a set of calculations with otherwise fixed parameters. The model agrees well with the experimental results, except for ivy, where the model overestimates the discrimination.

### 4.3 Discrimination against $\Delta^{17}\text{O}$ of $\text{CO}_2$

The discrimination of photosynthesis against  $\Delta^{17}\text{O}$  of  $\text{CO}_2$  ( $\Delta_A\Delta^{17}\text{O}$ ) is shown in Fig. 3b.  $\Delta_A\Delta^{17}\text{O}$  is negative for all experiments, it depends strongly on the  $c_m/c_a$  ratio, and  $|\Delta_A\Delta^{17}\text{O}|$  increases with  $c_m/c_a$  ratio. For instance, for  $\Delta^{17}\text{O}$  of  $\text{CO}_2$  entering the cuvette of  $-0.215\text{‰}$ ,  $\Delta_A\Delta^{17}\text{O}$  is  $-0.25\text{‰}$  for maize with  $c_m/c_a$  ratio of 0.3,  $-0.3\text{‰}$  for ivy with  $c_m/c_a$  ratio of 0.5, and  $-0.5\text{‰}$  for sunflower with  $c_m/c_a$  ratio of 0.7 (Fig. 3b). For sunflower and ivy,  $\Delta_A\Delta^{17}\text{O}$  is also strongly dependent on the  $\Delta^{17}\text{O}$  of  $\text{CO}_2$  supplied to the cuvette, whereas no significant dependence is found for maize. For an increase in  $\Delta^{17}\text{O}$  of  $\text{CO}_2$  entering the cuvette from  $-0.215\text{‰}$  to  $0.435\text{‰}$ ,  $\Delta_A\Delta^{17}\text{O}$  increases from  $-0.3\text{‰}$  to  $-0.9\text{‰}$  at  $c_m/c_a$  ratio of 0.5 for ivy. For sunflower, an increase in  $\Delta^{17}\text{O}$  of  $\text{CO}_2$  entering the cuvette from  $-0.215\text{‰}$  to  $0.31\text{‰}$  increases  $\Delta_A\Delta^{17}\text{O}$  from  $-0.8\text{‰}$  to  $-1.7\text{‰}$  at  $c_m/c_a$  ratio of 0.8. The leaf cuvette model results illustrate the shape of the dependence on the  $c_m/c_a$  ratio and agree well with the experiments. For the leaf cuvette model,

**Table 1.** Summary of gas exchange parameters and isotopic compositions of maize, sunflower, and ivy. Mole fraction at the site of exchange ( $c_m$ ) is calculated assuming complete isotopic equilibrium with the water at the  $\text{CO}_2\text{--H}_2\text{O}$  exchange site. The water at the  $\text{CO}_2\text{--H}_2\text{O}$  exchange site is assumed to be the same as the isotopic composition at the site of evaporation. Numbers in parentheses are the standard deviations of the mean ( $1\sigma$ ).

Parameter	Unit	Sunflower	Ivy	Maize	Irradiance ( $\mu\text{mol m}^{-2} \text{s}^{-1}$ )

		52.62 (1.42)	51.09 (1.76)	55.15 (1.55)	1200
$\Delta^{17}\text{O}_m$	$\text{‰}$	−0.41(0.001)	−0.35(0.001)	−0.40(0.01)	300
		−0.41(0.01)	−0.38(0.02)	−0.42(0.02)	1200
$c_a$	ppm	402 (3)	403 (3)	403 (3)	
$c_i$	ppm	357 (10)	284 (0.1)	194 (20)	300
		323 (10)	301 (13)	194 (15)	1200
$c_c$	ppm	277 (15)	188 (30)		300
		201 (42)	163 (21)		1200
$c_m$	ppm	320 (10)	220 (10)	134 (15)	300
		252 (27)	214 (12)	88 (17)	1200

the  $\Delta^{17}\text{O}$  value of the water is assigned a constant value of  $-0.122\text{‰}$  (average  $\Delta^{17}\text{O}$  value for the bulk leaf water).

Figure 4b shows the same values of  $\Delta_A \Delta^{17}\text{O}$  as a function of the difference between  $\Delta^{17}\text{O}$  of  $\text{CO}_2$  entering the leaf and the calculated  $\Delta^{17}\text{O}$  of leaf water at the evaporation site where  $\text{CO}_2\text{--H}_2\text{O}$  exchange takes place ( $\Delta^{17}\text{O}_a - \Delta^{17}\text{O}_{\text{wes}}$ ) for different  $c_m/c_a$  ratios. The leaf cuvette model results (solid lines in Fig. 4b) suggest a linear dependence between  $\Delta_A \Delta^{17}\text{O}$  and ( $\Delta^{17}\text{O}_a - \Delta^{17}\text{O}_{\text{wes}}$ ). The experimental results agree with the hypothesis that  $\Delta_A \Delta^{17}\text{O}$  is linearly dependent on  $\Delta^{17}\text{O}_a - \Delta^{17}\text{O}_{\text{wes}}$  at a certain  $c_m/c_a$  ratio. Figure 4a shows the corresponding relation where  $\Delta_A \Delta^{17}\text{O}$  is divided by  $\Delta^{17}\text{O}_a - \Delta^{17}\text{O}_m$ . All the values follow the same relationship as a function of the  $c_m/c_a$  ratio, which can be approx-

imated quite well by an exponential function (Eq. 5). This function quantifies the dependence of  $\Delta_A \Delta^{17}\text{O}$  on  $c_m/c_a$  and thus the effect of the diffusion of isotopically exchanged  $\text{CO}_2$  back to the atmosphere, which increases with increasing  $c_m/c_a$  ratio.

$$\frac{\Delta_A \Delta^{17}\text{O}}{\Delta^{17}\text{O}_a - \Delta^{17}\text{O}_m} = -0.150 \times \exp(3.707 \times c_m/c_a) + 0.028 \quad (5)$$

Figure 5a and c show results from the leaf cuvette model that illustrates in more detail how  $\Delta^{17}\text{O}_e$  and  $\Delta^{17}\text{O}_{\text{wes}}$  affect  $\Delta^{17}\text{O}_a$  and  $\Delta_A \Delta^{17}\text{O}$  and their dependence on  $c_m/c_a$ . At lower  $c_m/c_a$ , only a very small fraction of  $\text{CO}_2$  that has undergone isotopic equilibration in the mesophyll diffuses back to the atmosphere, and therefore  $\Delta^{17}\text{O}_a$  stays close to

**Table 2.** List of symbols and variables.

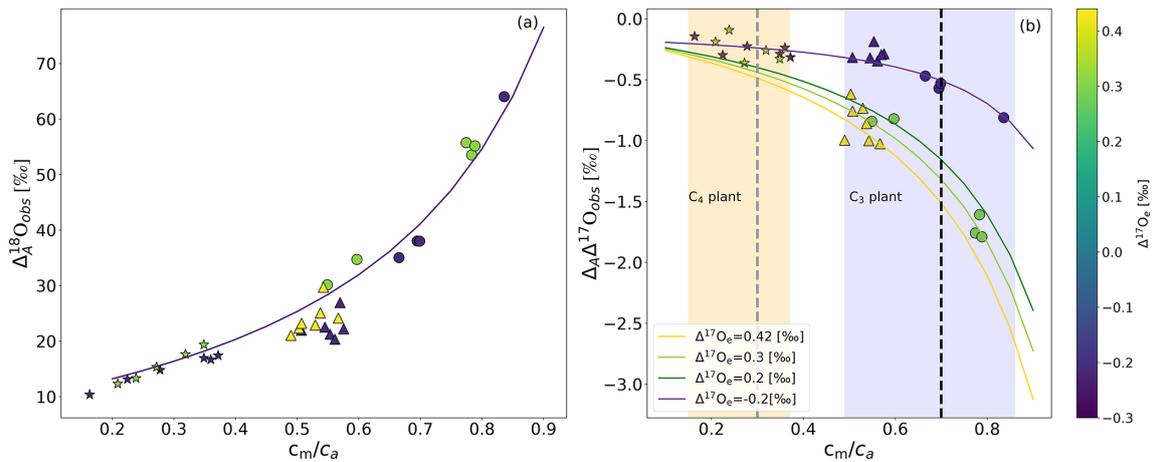

Symbol	Description	Unit/calculation/value
Gas exchange		
$A_n$	Rate of $\text{CO}_2$ assimilation	$\frac{u_e}{s} \left( c_e - c_a \left( \frac{1-w_e}{1-w_a} \right) \right)$ , $\text{mol m}^{-2} \text{s}^{-2}$
$E$	Transpiration rate	$\frac{u_e}{s} \left( \frac{w_a-w_e}{1-w_a} \right)$ , $\text{mol m}^{-2} \text{s}^{-2}$
$w_i$	Mole fraction of water vapor inside leaf	$613.65 \times e^{\left( \frac{17.502 \times T_{\text{leaf}}}{240.97 + T_{\text{leaf}}} \right)} \times 10^{-5}$ , $\text{mol mol}^{-1}$
$w_a$	Mole fraction of water vapor leaving the cuvette or leaf surrounding	$\text{mol mol}^{-1}$
$w_e$	Mole fraction of water vapor entering the cuvette	$\text{mol mol}^{-1}$
$c_e$	Mole fraction of $\text{CO}_2$ entering the cuvette	$\text{mol mol}^{-1}$
$c_a$	Mole fraction of $\text{CO}_2$ in the leaf surrounding or leaving the cuvette	$\text{mol mol}^{-1}$
$u_e$	Flow rate of air entering the cuvette	$\text{mol s}^{-1}$
$s$	Surface area of the leaf inside the cuvette	$\text{m}^{-2}$
$P$	Atmospheric pressure	bar
$T_{\text{leaf}}$	Leaf temperature	$^{\circ}\text{C}$
$g_{\text{s(H}_2\text{O)}}$	Stomatal conductance for water vapor	$\frac{g_{\text{H}_2\text{O}}^{\text{t}} \times g_{\text{b(H}_2\text{O)}}}{g_{\text{b(H}_2\text{O)}} - g_{\text{H}_2\text{O}}^{\text{t}}}$
$g_{\text{b(H}_2\text{O)}}$	Boundary layer conductance for water vapor	Calibrated for the cuvette we used
$g_{\text{H}_2\text{O}}^{\text{t}}$	Conductance for water vapor through the boundary layer and stomata	$E \left( \frac{1 - \left( \frac{w_i + w_a}{2} \right)}{w_i - w_a} \right)$ , $\text{mol m}^{-2} \text{s}^{-1}$
$g_{\text{s}}$	Stomatal conductance for $\text{CO}_2$	$\frac{g_{\text{s(H}_2\text{O)}}}{1.6}$
$g_{\text{b}}$	Boundary conductance for $\text{CO}_2$	$\frac{g_{\text{b(H}_2\text{O)}}}{1.37}$
$g_{\text{CO}_2}^{\text{t}}$	Conductance for $\text{CO}_2$ through the boundary layer and stomata	$\frac{g_{\text{s}} \times g_{\text{b}}}{g_{\text{s}} + g_{\text{b}}}$
$\Gamma^*$	$\text{CO}_2$ compensation point	$45 \mu\text{mol m}^{-2} \text{s}^{-1}$
$g_{\text{m}13}$	$\text{CO}_2$ conductance from intercellular air space to the site of carboxylation calculated using $\Delta_{\text{A}}^{13}\text{C}$ (for $\text{C}_3$ plants only)	$\text{mol m}^{-2} \text{s}^{-1} \text{bar}^{-1}$
$g_{\text{m}18}$	$\text{CO}_2$ conductance from intercellular air space to $\text{CO}_2\text{--H}_2\text{O}$ exchange site calculated using $\Delta_{\text{A}}^{18}\text{O}$	$\text{mol m}^{-2} \text{s}^{-1} \text{bar}^{-1}$
$g_{\text{m}17}$	$\text{CO}_2$ conductance from intercellular air space to $\text{CO}_2\text{--H}_2\text{O}$ exchange site calculated using $\Delta_{\text{A}}^{17}\text{O}$	$\text{mol m}^{-2} \text{s}^{-1} \text{bar}^{-1}$
$g_{\text{m}\Delta 17}$	$\text{CO}_2$ conductance from intercellular air space to $\text{CO}_2\text{--H}_2\text{O}$ exchange site calculated using $\Delta_{\text{A}} \Delta^{17}\text{O}$	$\text{mol m}^{-2} \text{s}^{-1} \text{bar}^{-1}$
$c_i$	Mole fraction of $\text{CO}_2$ in the intercellular air space	$\frac{\left( g_{\text{CO}_2}^{\text{t}} - \frac{E}{2} \right) c_a - A_n}{\left( g_{\text{CO}_2}^{\text{t}} + \frac{E}{2} \right)}$ $\text{mol mol}^{-1}$
$c_{\text{s}}$	Mole fraction of $\text{CO}_2$ at the leaf surface	$c_a - \frac{A_n}{g_{\text{b}}}$
$c_{\text{m}}$	Mole fraction of $\text{CO}_2$ at the site of $\text{CO}_2\text{--H}_2\text{O}$ exchange	$\text{mol mol}^{-1}$
$c_{\text{c}}$	Mesophyll conductance to the chloroplast (for $\text{C}_3$ plants)	$c_i - \frac{A_n}{g_{\text{m}13}}$ $\text{mol mol}^{-1}$
$t^{13}$	Ternary correction for $^{13}\text{CO}_2$	$\frac{(1+a_{13\text{bs}})E}{2g_{\text{CO}_2}^{\text{t}}}$
$t^{18}$	Ternary correction for $\text{C}^{18}\text{OO}$	$\frac{(1+a_{18\text{bs}})E}{2g_{\text{CO}_2}^{\text{t}}}$
$t^{17}$	Ternary correction for $\text{C}^{17}\text{OO}$	$\frac{(1+a_{17\text{bs}})E}{2g_{\text{CO}_2}^{\text{t}}}$
$R_{\text{D}}$	Dark respiration rate	$0.8 \mu\text{mol m}^{-2} \text{s}^{-1}$
$R_{\text{L}}$	Day respiration rate	$0.5 \times R_{\text{D}} \mu\text{mol m}^{-2} \text{s}^{-1}$

Symbol	Description	Unit/calculation/value
Oxygen and carbon isotope effects		
$\varepsilon_k^{18}$	Kinetic fractionation of water vapor in air	$\frac{28g_b+19g_s}{g_b+g_s}, \text{‰}$
$\varepsilon_{\text{equ}}^{18}$	Equilibrium fractionation between liquid and gas phase of water vapor	$2.644 - 3.206 \left( \frac{10^3}{T_{\text{leaf}}} \right) + 1.534 \left( \frac{10^6}{T_{\text{leaf}}} \right), \text{‰}$
$a_{13\text{bs}}$	Weighted fractionation for $^{13}\text{COO}$ as $\text{CO}_2$ diffuses through the boundary layer and stomata	$\frac{(c_s-c_i)a_{13\text{s}}+(c_a-c_s)a_{13\text{b}}}{c_a-c_i}, \text{‰}$
$a_{17\text{bs}}$	Weighted fractionation for $\text{C}^{17}\text{OO}$ as $\text{CO}_2$ diffuses through the boundary layer and stomata	$\frac{(c_s-c_i)a_{17\text{s}}+(c_a-c_s)a_{17\text{b}}}{c_a-c_i}, \text{‰}$
$a_{18\text{bs}}$	Weighted fractionation for $\text{C}^{18}\text{OO}$ as $\text{CO}_2$ diffuses through the boundary layer and stomata	$\frac{(c_s-c_i)a_{18\text{s}}+(c_a-c_s)a_{18\text{b}}}{c_a-c_i}, \text{‰}$
$a_{13\text{bs}}$	Weighted fractionation for $^{13}\text{COO}$ as $\text{CO}_2$ diffuses through the boundary layer and stomata	$\frac{(c_s-c_i)a_{13\text{s}}+(c_a-c_s)a_{13\text{b}}}{c_a-c_i}, \text{‰}$
$a_{18\text{bs}}$	Weighted fractionation for $\text{C}^{18}\text{OO}$ as $\text{CO}_2$ diffuses through the boundary layer and stomata	$\frac{(c_s-c_i)a_{18\text{s}}+(c_a-c_s)a_{18\text{b}}}{c_a-c_i}, \text{‰}$
$a_{17\text{bs}}$	Weighted fractionation for $\text{C}^{17}\text{OO}$ as $\text{CO}_2$ diffuses through the boundary layer and stomata	$\frac{(c_s-c_i)a_{17\text{s}}+(c_a-c_s)a_{17\text{b}}}{c_a-c_i}, \text{‰}$
$\bar{a}_{17}$	Weighted fractionation of $\text{C}^{17}\text{OO}$ as it diffuses through the boundary layer, stomata, and liquid phase in series	$\frac{(c_i-c_m)a_{17\text{w}}+(c_s-c_i)a_{17\text{s}}+(c_a-c_s)a_{17\text{b}}}{c_a-c_m}, \text{‰}$
$\bar{a}_{18}$	Weighted fractionation of $\text{C}^{18}\text{OO}$ as it diffuses through the boundary layer, stomata, and liquid phase in series	$\frac{(c_i-c_m)a_{18\text{w}}+(c_s-c_i)a_{18\text{s}}+(c_a-c_s)a_{18\text{b}}}{c_a-c_m}, \text{‰}$
$a_{13\text{b}}$	Fractionation in $^{13}\text{CO}_2$ as $\text{CO}_2$ diffuses through the boundary layer	2.9‰
$a_{13\text{s}}$	Fractionation in $^{13}\text{CO}_2$ as $\text{CO}_2$ diffuses through the stomata	4.4‰
$a_m$	Fractionation factor for dissolution and diffusion through water	1.8‰
$f$	Fractionation factor for photorespiration (decarboxylation of glycine)	16‰
$e$	Fractionation factor for day respiration	$R_D + e^*, \text{‰}$
$e^*$	Apparent fractionation for day respiration	$\delta^{13}\text{C}_a - \Delta_{\text{A}}^{13}\text{C} - \delta^{13}\text{C}_{\text{substrate}}, \text{‰}$
$b$	Fractionation factor for uptake by RuBisCO	29‰
$\alpha_f$	Fractionation due to photorespiration (decarboxylation of glycine)	$1 + f$
$\alpha_e$	Fractionation due to day respiration	$1 + e$
$\alpha_b$	Fractionation due to uptake by RuBisCO	$1 + b$
$a_{17\text{b}}$	Fractionation of $\text{C}^{17}\text{OO}$ as $\text{CO}_2$ diffuses through the boundary layer	2.9‰
$a_{17\text{s}}$	Fractionation in $\text{C}^{17}\text{OO}$ as $\text{CO}_2$ diffuses through stomata	4.4‰
$a_{18\text{b}}$	Fractionation of $\text{C}^{18}\text{OO}$ as $\text{CO}_2$ diffuses through the boundary layer	5.8‰
$a_{18\text{s}}$	Fractionation in $\text{C}^{18}\text{OO}$ as $\text{CO}_2$ diffuses through stomata	8.8‰
$a_{17\text{w}}$	Fractionation in $\text{C}^{17}\text{OO}$ due to diffusion and dissolution in water	0.382‰
$a_{18\text{w}}$	Fractionation in $\text{C}^{18}\text{OO}$ due to diffusion and dissolution in water	0.8‰
$\varepsilon_{\text{W}}^{18}$	Equilibrium fractionation of $\text{CO}_2$ and water for $\text{C}^{18}\text{OO}$	$\frac{17604}{T_{\text{leaf}}} - 17.93, \text{‰}$
$\varepsilon_k^{18}$	kinetic fractionation of water vapor in air	$\frac{28 \times g_b + 19 \times g_s}{g_b + g_s}$
$\varepsilon_{\text{equ}}^{18}$	equilibrium fractionation between liquid- and gas-phase water	$2.644 - 3.206 \times \left( \frac{10^3}{T} \right) + 1.534 \times \left( \frac{10^6}{T} \right)$

Table 2. Continued.

Symbol	Description	Unit/calculation/value
Isotopic composition		
$\delta^{17}\text{O}_A$	$\delta^{17}\text{O}$ of the assimilated $\text{CO}_2$	$\frac{\delta^{17}\text{O}_a - \Delta_A^{17}\text{O}}{\Delta_A^{17}\text{O} + 1} = \delta^{17}\text{O}_a - \frac{c_e}{c_e - c_a} (\delta^{17}\text{O}_a - \delta^{17}\text{O}_e)$
$\delta^{18}\text{O}_A$	$\delta^{18}\text{O}$ of the assimilated $\text{CO}_2$	$\frac{\delta^{18}\text{O}_a - \Delta_A^{18}\text{O}}{\Delta_A^{18}\text{O} + 1} = \delta^{18}\text{O}_a - \frac{c_e}{c_e - c_a} (\delta^{18}\text{O}_a - \delta^{18}\text{O}_e)$
$\delta^{17}\text{O}_{\text{io}}$	$\delta^{17}\text{O}$ of $\text{CO}_2$ in the intercellular air space ignoring ternary correction	$\delta^{17}\text{O}_A \left(1 - \frac{c_a}{c_i}\right) (1 + a_{17\text{bs}}) + \frac{c_a}{c_i} (\delta^{17}\text{O}_a - a_{17\text{bs}}) + a_{17\text{bs}}, \text{‰}$
$\delta^{18}\text{O}_{\text{io}}$	$\delta^{18}\text{O}$ of $\text{CO}_2$ in the intercellular air space ignoring ternary correction	$\delta^{18}\text{O}_A \left(1 - \frac{c_a}{c_i}\right) (1 + a_{18\text{bs}}) + \frac{c_a}{c_i} (\delta^{18}\text{O}_a - a_{18\text{bs}}) + a_{18\text{bs}}, \text{‰}$
$\delta^{17}\text{O}_i$	$\delta^{17}\text{O}$ of $\text{CO}_2$ in the intercellular air space	$\frac{\delta^{17}\text{O}_{\text{io}} + t^{17} (\delta^{17}\text{O}_A (\frac{c_a}{c_i} + 1) - \delta^{17}\text{O}_a \frac{c_a}{c_i})}{1 + t^{17}}, \text{‰}$
$\delta^{18}\text{O}_i$	$\delta^{18}\text{O}$ of $\text{CO}_2$ in the intercellular air space	$\frac{\delta^{18}\text{O}_{\text{io}} + t^{18} (\delta^{18}\text{O}_A (\frac{c_a}{c_i} + 1) - \delta^{18}\text{O}_a \frac{c_a}{c_i})}{1 + t^{18}}, \text{‰}$
$\delta^{18}\text{O}_{\text{trans}}$	$\delta^{18}\text{O}$ of transpired water vapor	$\left(\frac{w_a}{w_a - w_c}\right) (\delta^{18}\text{O}_{\text{wa}} - \delta^{18}\text{O}_{\text{we}}) + \delta^{18}\text{O}_{\text{we}}, \text{‰}$
$\delta^{18}\text{O}_{\text{wes}}$	$\delta^{18}\text{O}$ of water at the evaporation site	$\delta^{18}\text{O}_{\text{wes}} = \delta^{18}\text{O}_{\text{trans}} + \varepsilon_k^{18} + \varepsilon_{\text{equ}}^{18} + \frac{w_a}{w_i} \times (\delta^{18}\text{O}_{\text{wa}} - \varepsilon_k^{18} + \delta^{18}\text{O}_{\text{trans}})$
$\delta^{17}\text{O}_m$	$\delta^{17}\text{O}$ of $\text{CO}_2$ at the site of $\text{CO}_2$ – $\text{H}_2\text{O}$ exchange	$(\delta^{17}\text{O}_{\text{wes}} + 1) \times (1 + \varepsilon_w^{17}) - 1, \text{‰}$
$\delta^{18}\text{O}_m$	$\delta^{18}\text{O}$ of $\text{CO}_2$ at the site of $\text{CO}_2$ – $\text{H}_2\text{O}$ exchange	$(\delta^{18}\text{O}_{\text{wes}} + 1) \times (1 + \varepsilon_w^{18}) - 1, \text{‰}$
$\delta^{13}\text{C}_{\text{substrate}}$	Isotope ( $^{13}\text{C}$ ) ratio of substrate used for dark respiration	$\frac{\delta^{13}\text{C}_a - \Delta_A^{13}\text{C}}{\Delta_A^{13}\text{C} + 1}, \text{‰}$
$\Delta_A^{13}\text{C}$	$^{13}\text{C}$ -photosynthetic discrimination	$\frac{\zeta (\delta^{13}\text{C}_a - \delta^{13}\text{C}_c)}{1 + \delta^{13}\text{C}_a - (\delta^{13}\text{C}_a - \delta^{13}\text{C}_c)}, \text{‰}$
$\Delta_A^{13}\text{C}_{\text{obs}}$	$^{13}\text{C}$ -photosynthetic discrimination (Farquhar model)	$\left(\frac{1}{1-t}\right) \left[ a_{13\text{bs}} \frac{c_a - c_i}{c_a} \right] + \left(\frac{1+t}{1-t}\right) \left[ a_m \frac{c_i - c_c}{c_a} + b \frac{c_c}{c_a} - \frac{\alpha_b}{\alpha_c} e \frac{R_D}{R_D + A_n} \frac{c_c - \Gamma^*}{c_a} - \frac{\alpha_b}{\alpha_f} f \frac{\Gamma^*}{c_a} \right]$
$\Delta_A^{13}\text{C}_i$	$^{13}\text{C}$ -photosynthetic discrimination (assuming no mesophyll conductance, i.e., $c_i = c_c$ )	$\left(\frac{1}{1-t}\right) \left[ a \frac{c_a - c_i}{c_a} \right] + \left(\frac{1+t}{1-t}\right) \left[ b \frac{c_i}{c_a} - \frac{\alpha_b}{\alpha_c} e \frac{R_D}{R_D + A_n} \frac{c_i - \Gamma^*}{c_a} - \frac{\alpha_b}{\alpha_f} f \frac{\Gamma^*}{c_a} \right]$
$\Delta_A^{18}\text{O}$	$^{18}\text{O}$ -photosynthetic discrimination	$\frac{\zeta (\delta^{18}\text{O}_a - \delta^{18}\text{O}_e)}{1 + \delta^{18}\text{O}_a - \zeta (\delta^{18}\text{O}_a - \delta^{18}\text{O}_e)}, \text{‰}$
$\Delta_A^{17}\text{O}$	$^{17}\text{O}$ -photosynthetic discrimination	$\frac{\zeta (\delta^{17}\text{O}_a - \delta^{17}\text{O}_e)}{1 + \delta^{17}\text{O}_a - \zeta (\delta^{17}\text{O}_a - \delta^{17}\text{O}_e)}, \text{‰}$
$\Delta_A^{17}\text{O}_{\text{FM}}$	Farquhar model for $^{17}\text{O}$ -photosynthetic discrimination	$\frac{\bar{a}_{17} + \frac{c_m}{c_a - c_m} \delta^{17}\text{O}_{\text{ma}}}{1 - \frac{c_m}{c_a - c_m} \delta^{17}\text{O}_{\text{ma}}}, \text{‰}$
$\Delta_A^{18}\text{O}_{\text{FM}}$	Farquhar model for $^{18}\text{O}$ -photosynthetic discrimination	$\frac{\bar{a}_{18} + \frac{c_m}{c_a - c_m} \delta^{18}\text{O}_{\text{ma}}}{1 - \frac{c_m}{c_a - c_m} \delta^{18}\text{O}_{\text{ma}}}, \text{‰}$
$\delta^{17}\text{O}_e$	$\delta^{17}\text{O}$ of $\text{CO}_2$ entering the cuvette	$\text{‰}$

$\delta^{18}\text{O}_e$	$\delta^{18}\text{O}$ of $\text{CO}_2$ entering the cuvette	$\text{‰}$
$\delta^{18}\text{O}_a$	$\delta^{18}\text{O}$ of $\text{CO}_2$ leaving the cuvette	$\text{‰}$
$\delta^{17}\text{O}_{\text{ma}}$	$\delta^{17}\text{O}$ of $\text{CO}_2$ equilibrated with the leaf water at the evaporating site relative to the $\text{CO}_2$ leaving the cuvette	$\frac{\delta^{17}\text{O}_m - \delta^{17}\text{O}_a}{1 - \delta^{18}\text{O}_a}, \text{‰}$
$\delta^{18}\text{O}_{\text{ma}}$	$\delta^{18}\text{O}$ of $\text{CO}_2$ equilibrated with the leaf water at the evaporating site relative to the $\text{CO}_2$ leaving the cuvette	$\frac{\delta^{18}\text{O}_m - \delta^{18}\text{O}_a}{1 - \delta^{18}\text{O}_a}, \text{‰}$
$\delta^{18}\text{O}_{\text{we}}$	$\delta^{18}\text{O}$ of water vapor entering the cuvette	$\text{‰}$
$\delta^{18}\text{O}_{\text{wa}}$	$\delta^{18}\text{O}$ of water vapor leaving the cuvette or leaf surrounding	$\text{‰}$

**Figure 3.** (a)  $\Delta_A^{18}\text{O}_{\text{obs}}$  during photosynthesis for two C<sub>3</sub> plants, sunflower (circles) and ivy (triangles), and C<sub>4</sub> plant maize (stars), as a function of  $c_m/c_a$ . The solid lines show results from the leaf cuvette model, where  $\delta^{18}\text{O}$  of the  $\text{CO}_2$  entering the cuvette is 30.47 ‰. (b)  $\Delta_A \Delta^{17}\text{O}$  of  $\text{CO}_2$  as a function of  $c_m/c_a$  for isotopically different  $\text{CO}_2$  gases entering the cuvette (color bar shows  $\Delta^{17}\text{O}_e$ ) for sunflower (circles), ivy (triangles), and maize (stars).  $\Delta_A \Delta^{17}\text{O}$  values calculated using the leaf cuvette model are shown as solid lines in corresponding colors ( $\Delta^{17}\text{O}_e$  values are given in the legend). The shaded areas indicate the  $c_m/c_a$  ranges for C<sub>4</sub> and C<sub>3</sub> plants, and the vertical dashed lines indicate the mean  $c_m/c_a$  ratio used for extrapolating from the leaf scale to the global scale. The solid line is the leaf cuvette model results for the corresponding  $c_m/c_a$  ratio.

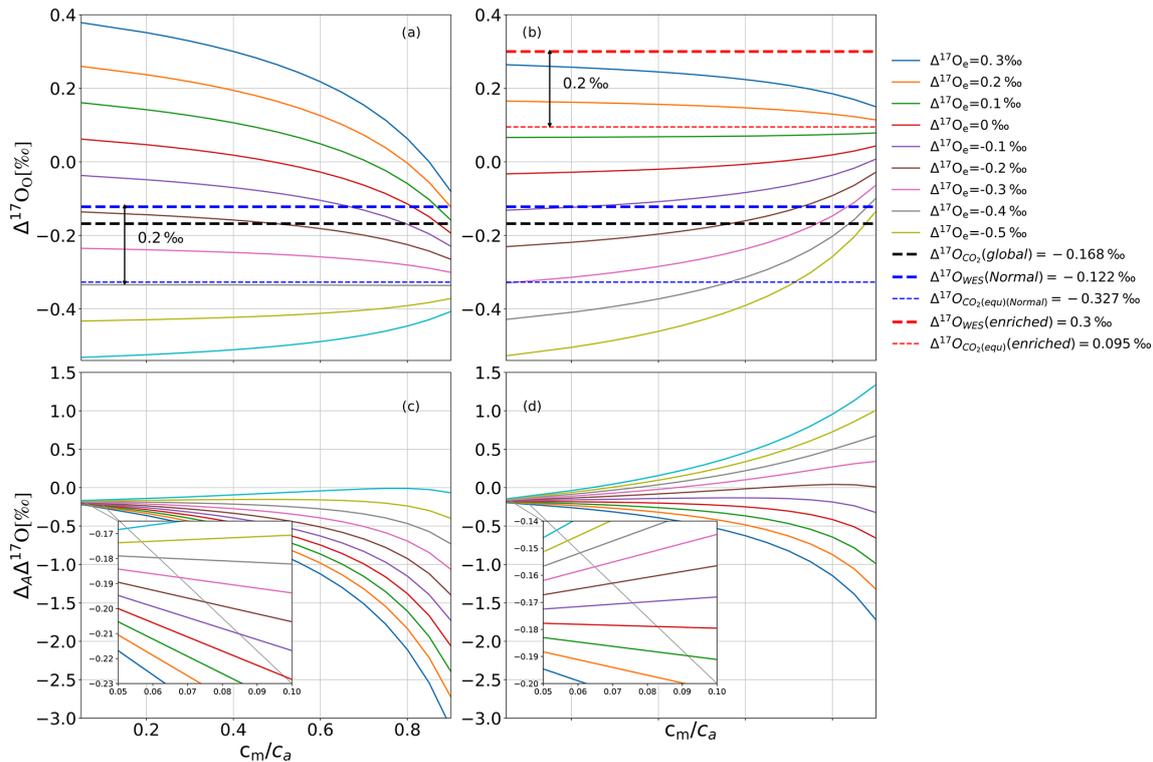

**Figure 4.** (a) Dependency of  $\Delta_A \Delta^{17}\text{O}$  on the relative difference of the  $\Delta^{17}\text{O}(\text{CO}_2)$  entering the leaf and the  $\Delta^{17}\text{O}$  of  $\text{CO}_2$  in equilibrium with leaf water against the  $c_m/c_a$  ratio. (b) Dependency of  $\Delta_A \Delta^{17}\text{O}$  on the difference between the  $\Delta^{17}\text{O}$  of  $\text{CO}_2$  entering the cuvette and the  $\Delta^{17}\text{O}$  of leaf water at the evaporation site color coded for different  $c_m/c_a$  ratios. The solid lines are the results of the leaf cuvette model for different  $c_m/c_a$  ratios as stated in the legend. The vertical dashed black line indicates the difference between the global average  $\Delta^{17}\text{O}$  value for  $\text{CO}_2$  ( $-0.168$  ‰) and leaf water ( $-0.067$  ‰) (Koren et al., 2019). The gray and yellow horizontal dashed lines indicate global  $\Delta_A \Delta^{17}\text{O}$  of C<sub>4</sub> and C<sub>3</sub> plants for a  $c_m/c_a$  ratio of 0.3 and 0.7, respectively.

the incoming  $\Delta^{17}\text{O}_e$ , modified by the fractionation during  $\text{CO}_2$  diffusion through the stomata (Fig. 5a). Figure 5c confirms that at low  $c_m/c_a$ ,  $\Delta_A \Delta^{17}\text{O}$  approaches the fractionation constant expected for diffusion,  $-0.170$  ‰. This diffusional fractionation is independent of the isotopic composition of the  $\text{CO}_2$  entering the leaf, and therefore at low  $c_m/c_a$ , the  $\Delta_A \Delta^{17}\text{O}$  curves for the different values of the anomaly of the  $\text{CO}_2$  entering the leaf converge. For a high  $c_m/c_a$  ratio, the back-diffusion flux of  $\text{CO}_2$  that has equilibrated with water becomes the dominant factor, and, in this case, the iso-

topic composition of the outgoing  $\text{CO}_2$  converges towards this isotope value, independent of the isotopic composition of the incoming  $\text{CO}_2$  (Fig. 5a). This can lead to a very wide range of values for the discrimination against  $\Delta^{17}\text{O}$  because now the effect on  $\Delta^{17}\text{O}$  of the ambient  $\text{CO}_2$  depends strongly on the difference in isotopic composition between incoming  $\text{CO}_2$  and  $\text{CO}_2$  in isotopic equilibrium with the leaf water.

In the model calculations shown in Fig. 5b and d, the isotopic composition of the water was changed from  $\Delta^{17}\text{O}_{\text{wes}} = -0.122$  ‰ to  $0.300$  ‰, whereas all other parameters were

**Figure 5.** (a, b)  $\Delta^{17}\text{O}_a$  as a function of  $c_m/c_a$  for various values of  $\Delta^{17}\text{O}_e$  (see legend) for  $\Delta^{17}\text{O}_{\text{wes}} = -0.122\text{‰}$  in (a) and  $\Delta^{17}\text{O}_{\text{wes}} = 0.300\text{‰}$  in (b). Panels (c, d) show the corresponding values for  $\Delta_A \Delta^{17}\text{O}$ .  $\Delta^{17}\text{O}_{\text{global}}$  is the global average  $\Delta^{17}\text{O}$  value for atmospheric  $\text{CO}_2$  (Koren et al., 2019). When  $\Delta^{17}\text{O}$  of  $\text{CO}_2$  entering the cuvette is approximately  $0.2\text{‰}$  lower than the  $\Delta^{17}\text{O}$  of leaf water at the  $\text{CO}_2\text{--H}_2\text{O}$  exchange site,  $\Delta^{17}\text{O}$  of the  $\text{CO}_2$  leaving the cuvette does not change when the  $c_m/c_a$  ratio varies.

kept the same. The value of  $\Delta^{17}\text{O}_e$  for which  $\Delta^{17}\text{O}_a$  does not depend on  $c_m/c_a$  is shifted accordingly, again being similar to  $\Delta^{17}\text{O}_m$ . At low  $c_m/c_a$ ,  $\Delta_A \Delta^{17}\text{O}$  converges to the same value as in Fig. 5c, confirming the role of diffusion into the stomata as discussed above.

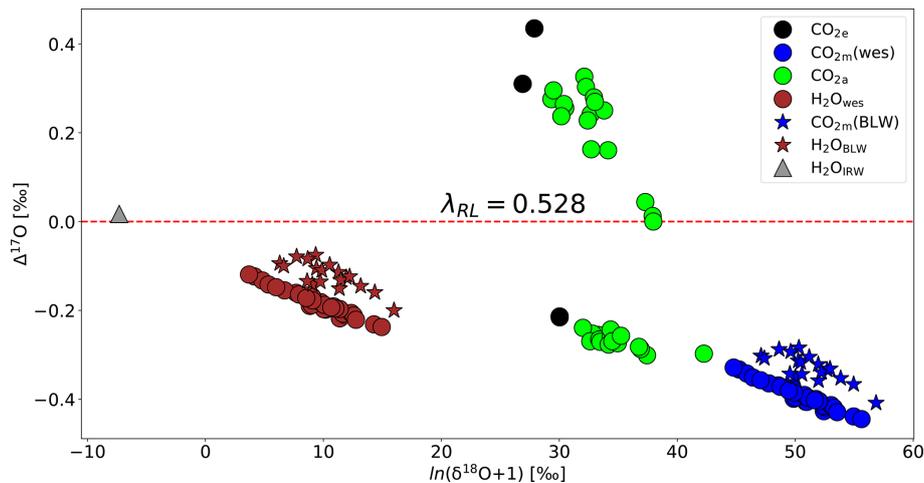

Figure 6 shows how  $\delta^{18}\text{O}$  and  $\Delta^{17}\text{O}$  vary in key compartments of the leaf cuvette system that determine the oxygen isotope effects associated with photosynthesis, based on the previously established three-isotope slopes of the various processes (Fig. 1). The irrigation water has a  $\Delta^{17}\text{O}$  value of  $0.017\text{‰}$ . The measured bulk leaf water is  $6\text{‰}$  to  $16\text{‰}$  enriched in  $^{18}\text{O}$  and its  $\Delta^{17}\text{O}$  value is lower by  $-0.075\text{‰}$  to  $-0.200\text{‰}$  (mean value  $-0.121\text{‰}$ ) than the irrigation water, calculated using a three-isotope slope of  $\theta_{\text{trans}} = 0.516\text{‰}$  at  $80\%$  humidity (Landais et al., 2006).  $\Delta^{17}\text{O}$  of leaf water at the evaporation site, calculated from the transpired water, has slightly lower  $\Delta^{17}\text{O}$ , with values between  $-0.119\text{‰}$  and  $-0.237$  (average  $-0.184\text{‰}$ ). Note that the bulk leaf water was not measured for all the experiments. For the experiments where the bulk leaf water is measured,  $\Delta^{17}\text{O}$  of leaf water at the evaporation site ranges from  $-0.160\text{‰}$  to  $-0.231\text{‰}$  with an average value of  $-0.190 \pm 0.020\text{‰}$ . The calculated isotopic composition of water at the exchange site was thus similar but slightly lower in  $\Delta^{17}\text{O}$  than the values

measured for bulk leaf water.  $\text{CO}_2$  exchanges with the water in the leaf with a well-established fractionation constant (see Eq. S17) and a three-isotope slope of  $\theta_{\text{CO}_2\text{--H}_2\text{O}} = 0.5229$  (Barkan and Luz, 2012), leading to the lower  $\Delta^{17}\text{O}$  values of the equilibrated  $\text{CO}_2$ . In our experiments, the  $\Delta^{17}\text{O}$  value of  $\text{CO}_2$  in equilibrium with leaf water is lower than the  $\Delta^{17}\text{O}$  value of  $\text{CO}_2$  entering the leaf. The  $\Delta^{17}\text{O}$  of the  $\text{CO}_2$  in the intercellular air space is a mixture between two end-members, the  $\Delta^{17}\text{O}$  of the  $\text{CO}_2$  entering the leaf and  $\Delta^{17}\text{O}$  of the  $\text{CO}_2$  in equilibrium with leaf water. This explains why the observed values of  $\Delta_A \Delta^{17}\text{O}$  are negative for the experiments performed in this study.

## 5 Discussion

### 5.1 Discrimination against $\delta^{18}\text{O}$ of $\text{CO}_2$

The higher  $\Delta_A^{18}\text{O}_{\text{obs}}$  values for sunflower compared to maize and ivy (Fig. 3a) are mainly due to a higher back-diffusion flux ( $c_m/(c_a - c_m)$ ). The back-diffusion flux is higher for the  $\text{C}_3$  plants sunflower and ivy than for the  $\text{C}_4$  plant maize, a consequence of the lower stomatal conductance and higher assimilation rate of  $\text{C}_4$  plants (Gillon and Yakir, 2000a; Barbour et al., 2016). In  $\text{C}_4$  plants most of the  $\text{CO}_2$  entering

**Figure 6.** Isotopic composition of various relevant oxygen reservoirs that affect the  $\Delta^{17}\text{O}$  of atmospheric  $\text{CO}_2$  during photosynthesis: irrigation water (gray triangle), calculated leaf water at the evaporation site (brown circles), measured bulk leaf water (brown star),  $\text{CO}_2$  entering the cuvette (black circles),  $\text{CO}_2$  leaving the leaf cuvette (green circles),  $\text{CO}_2$  equilibrated with leaf water at the evaporation site (blue circles), and  $\text{CO}_2$  equilibrated with bulk leaf water (blue stars).  $\Delta^{17}\text{O}$  is calculated with  $\lambda = 0.528$ .

the stomata is carboxylated by phosphoenolpyruvate carboxylase (PEPC), resulting in a lower  $\text{CO}_2$  mixing ratio in the mesophyll, which results in a lower back-diffusion flux. The increase in assimilation rate with higher light intensity decreases the  $c_m/c_a$  ratio and thus leads to a lower back-diffusion flux, which explains the decreases in  $\Delta_A^{18}\text{O}_{\text{obs}}$  for maize and most clearly for sunflower. A similar trend of increase in  $\Delta_A^{18}\text{O}_{\text{obs}}$  with an increase in  $c_m/c_a$  ratio has been reported in previous studies (Gillon and Yakir, 2000b, a; Osborn et al., 2017). For ivy,  $\Delta_A^{18}\text{O}_{\text{obs}}$  and  $\Delta_A^{17}\text{O}_{\text{obs}}$  do not decrease with an increase in irradiance because the change in assimilation rate with irradiance is small. Thus,  $c_m$  will not decrease strongly and the effect on the back diffusion is smaller than the variability in  $\Delta_A^{18}\text{O}_{\text{obs}}$  of different leaves of the same plant.

In our experiments, photosynthesis causes an enrichment in the  $\delta^{18}\text{O}$  of atmospheric  $\text{CO}_2$  for both  $\text{C}_3$  and  $\text{C}_4$  plants, i.e., positive value of  $\Delta_A^{18}\text{O}$ . In principle,  $\Delta_A^{18}\text{O}$  can also be negative if the  $\delta^{18}\text{O}_m$  is depleted relative to the ambient  $\text{CO}_2$ . This is in contrast to  $\Delta_A^{13}\text{C}$ , which will always be positive since it is determined by the fractionation due to the PEPC and RuBisCO enzyme activity (Figs. S8 and S9). In general, in our experiments the  $\Delta_A^{18}\text{O}_{\text{obs}}$  values are about 5 times larger than  $\delta^{18}\text{O}_a - \delta^{18}\text{O}_e$ , the  $\delta^{18}\text{O}$  difference between  $\text{CO}_2$  entering and leaving the cuvette (Figs. S10 to S12). This is easy to understand from the definition of  $\Delta_A$ . Taking  $\Delta_A^{18}\text{O}$  as an example,  $\Delta_A^{18}\text{O}_{\text{obs}} = \frac{\zeta(\delta^{18}\text{O}_a - \delta^{18}\text{O}_e)}{1 + \delta^{18}\text{O}_a - \zeta(\delta^{18}\text{O}_a - \delta^{18}\text{O}_e)} \approx (\delta^{18}\text{O}_a - \delta^{18}\text{O}_e)$ , and in our experiments  $\zeta = c_e / (c_e - c_a) \approx 500 / (500 - 400) = 5$ .

## 5.2 Discrimination against the $\Delta^{17}\text{O}$ of $\text{CO}_2$

The leaf cuvette model includes the isotope fractionations of all the individual processes that have been quantified in dedicated experiments previously (Fig. 1). The good agreement of the model results with the measurements (Fig. 3a) demonstrates that when all these processes are combined in the quantitative description of a gas exchange experiment, they actually result in a correct quantification of the isotope effects associated with photosynthesis. This has already been demonstrated before for  $\Delta_A^{18}\text{O}_{\text{obs}}$  but has now been confirmed for  $\Delta_A \Delta^{17}\text{O}$ .

Unlike ivy and sunflower, maize does not show a significant change in  $\Delta_A \Delta^{17}\text{O}$  when  $\text{CO}_2$  gases with different  $\Delta^{17}\text{O}$  are supplied to the plant. The  $\text{C}_4$  plant maize has a small back-diffusion flux due to its high assimilation rate and low stomatal conductance, leading to a low  $c_m/c_a$  ratio. At low  $c_m/c_a$  ratios,  $\Delta_A \Delta^{17}\text{O}$  is expected to be close to the weighted fractionation due to diffusion through boundary layer and stomata. In general, the effect of diffusion on  $\Delta^{17}\text{O}$  of atmospheric  $\text{CO}_2$  can be expressed as follows:

$$\Delta^{17}\text{O}_{\text{Modified}} = \Delta^{17}\text{O}_a + (\lambda_{\text{RL}} - \theta_{\text{CO}_2\text{-diff}}) \times \ln \alpha_{\text{diffusion}}, \quad (6)$$

where  $\Delta^{17}\text{O}_a$  is the  $\Delta^{17}\text{O}$  of the  $\text{CO}_2$  surrounding the leaf;  $\Delta^{17}\text{O}_{\text{modified}}$  is the  $\Delta^{17}\text{O}$  of the  $\text{CO}_2$  modified due to diffusional fractionation; and  $\theta_{\text{CO}_2\text{-diff}}$ ,  $\lambda_{\text{RL}}$ , and  $\alpha_{\text{diffusion}}$  are the oxygen three-isotope relationships during diffusion from the  $\text{CO}_2\text{-H}_2\text{O}$  exchange site to the atmosphere, the reference slope used, and the fractionation against  $^{18}\text{O}$  for  $\text{CO}_2$  during diffusion through the stomata. Using the values  $\lambda_{\text{RL}} = 0.528$ ,  $\theta_{\text{CO}_2\text{-diff}} = 0.509$  (Young et al., 2002), and  $\alpha_{\text{diffusion}} = 0.9912$  (Farquhar and Lloyd, 1993), the effect of diffusional fractionation on the  $\Delta^{17}\text{O}$  of atmospheric  $\text{CO}_2$  is

$-0.168\text{‰}$  regardless of the anomaly of the  $\text{CO}_2$  entering the leaf, and the model results confirm this at low  $c_m/c_a$  ratios (Fig. 5c and d, inset).

At a high  $c_m/c_a$  ratio,  $\Delta^{17}\text{O}_a$  is dominated by the back-diffusion flux of  $\text{CO}_2$  that has equilibrated with water. As a consequence,  $\Delta^{17}\text{O}_a$  converges to a common value that is independent of the anomaly of the  $\text{CO}_2$  entering the cuvette and is determined by the isotopic composition of leaf water. Figure 5 confirms that the end-member is equal to the  $\Delta^{17}\text{O}$  of  $\text{CO}_2$  in equilibrium with leaf water,  $\Delta^{17}\text{O}_m$ . In fact, when  $\Delta^{17}\text{O}_a = \Delta^{17}\text{O}_m$ ,  $\Delta^{17}\text{O}_a$  does not change with  $c_m/c_a$ , indicating that in this case the  $\Delta^{17}\text{O}$  of the  $\text{CO}_2$  diffusing back from the leaf is the same as the  $\Delta^{17}\text{O}(\text{CO}_2)$  entering the leaf.

$\bar{a}_{18}$  is the overall discrimination occurring during the diffusion of  $^{12}\text{C}^{18}\text{O}^{16}\text{O}$  from the ambient air surrounding the leaf to the  $\text{CO}_2\text{-H}_2\text{O}$  exchange site (see Table 2 for the list of variables). In our study  $\bar{a}_{18}$  ranges from  $5\text{‰}$  to  $7.2\text{‰}$ , lower than the literature estimate of  $7.4\text{‰}$  (Farquhar et al., 1993).  $\bar{a}_{18}$  depends on the ratio of stomatal conductance, which is associated with a strong fractionation of  $8.8\text{‰}$ , to mesophyll conductance with an associated fractionation of only  $0.8\text{‰}$ . Therefore, the higher the ratio ( $g_s/g_{m18}$ ) the lower the  $\bar{a}_{18}$  (Table S2). The difference in  $\bar{a}_{18}$  of  $2.4\text{‰}$  between the literature value of  $7.4\text{‰}$  and the lowest  $\bar{a}_{18}$  estimate in this study will introduce an error of only  $0.046\text{‰}$  in the  $\Delta^{17}\text{O}$  value (see Eq. 6). The uncertainty  $\bar{a}_{18}$  has lower influence on the  $\Delta_A\Delta^{17}\text{O}$  of  $\text{C}_3$  plants compared to  $\text{C}_4$  plants since the diffusional fractionation is less important at the higher  $c_m/c_a$  ratio where  $\text{C}_3$  plants operate.

### 5.3 Global average value of $\Delta_A\Delta^{17}\text{O}$ and $\Delta^{17}\text{O}$ isoflux

We can use the established relationship between  $\Delta_A\Delta^{17}\text{O}$  and  $\Delta^{17}\text{O}_a - \Delta^{17}\text{O}_{\text{wes}}$  for a certain  $c_m/c_a$  ratio to provide a bottom-up estimate for the global effect of photosynthesis on  $\Delta^{17}\text{O}$  in atmospheric  $\text{CO}_2$ , based on data obtained in real gas exchange experiments. For this, we use results from a recent modeling study, which provides global average values for  $\text{CO}_2$  and leaf water ( $\Delta^{17}\text{O}(\text{CO}_2) = -0.168\text{‰}$ ,  $\Delta^{17}\text{O}(\text{H}_2\text{O}_{\text{-leaf}}) = -0.067\text{‰}$ ; Koren et al., 2019; Figs. S13 and 14). The  $\Delta^{17}\text{O}(\text{CO}_2)$  values agree well with the limited amount of available measurements (Table 3).

To extrapolate  $\Delta_A\Delta^{17}\text{O}$  determined in the leaf-scale experiments to the global scale, global average  $c_m/c_a$  ratios of 0.7 and 0.3 are used for  $\text{C}_3$  and  $\text{C}_4$  plants, respectively, similar to previous studies (Hoag et al., 2005; Liang et al., 2017b). From the SIBCASA model results we obtained an annual variability of  $c_i/c_a$  values with a standard deviation of 0.12 and 0.17 for  $\text{C}_4$  and  $\text{C}_3$  plants, respectively (Fig. S15) (Schaefer et al., 2008; Koren et al., 2019). We use this variability as the upper limit of the error estimate for  $c_m/c_a$ , as shown in the light orange and light pink shaded areas in Fig. 4b. This error is converted to an error in  $\Delta_A\Delta^{17}\text{O}$  using the relation with  $c_m/c_a$ . Based on the linear dependency of  $\Delta_A\Delta^{17}\text{O}$  and  $\Delta^{17}\text{O}_a - \Delta^{17}\text{O}_{\text{wes}}$ , we estimate the  $\Delta_A\Delta^{17}\text{O}$

for tropospheric  $\text{CO}_2$  based on the  $\Delta^{17}\text{O}$  of leaf water and  $c_m/c_a$  ratio. In Fig. 4b, the vertical dashed black line indicates  $\Delta^{17}\text{O}_a - \Delta^{17}\text{O}_{\text{wes}}$  obtained from the 3D global model (Koren et al., 2019). The results of the global estimate and parameters used for the extrapolation of a leaf-scale study to the global scale are summarized in Table 3.

The  $\delta^{17}\text{O}$  value of atmospheric  $\text{CO}_2$  ( $21.53\text{‰}$ ) is calculated from the global  $\delta^{18}\text{O}$  and  $\Delta^{17}\text{O}$  values ( $41.5\text{‰}$  and  $-0.168\text{‰}$ , respectively) (Koren et al., 2019). The  $\delta^{17}\text{O}$  and  $\delta^{18}\text{O}$  values of global mean leaf water are calculated from the soil water. A global mean  $\delta^{18}\text{O}$  value of soil water is  $-8.4\text{‰}$  assuming soil water to be similar to precipitation (Bowen and Revenaugh, 2003; Koren et al., 2019). The  $\delta^{17}\text{O}$  value of soil water is  $-4.4\text{‰}$ , calculated using Eq. (7) (Luz and Barkan, 2010).

$$\ln(\delta^{17}\text{O}_{\text{soil}} + 1) = 0.528 \times \ln(\delta^{18}\text{O}_{\text{soil}} + 1) + 0.033 \quad (7)$$

$\delta^{17}\text{O}$  and  $\delta^{18}\text{O}$  of leaf water are calculated from  $\delta^{17}\text{O}$  and  $\delta^{18}\text{O}$  of soil water with fractionation factors of 1.0043 and 1.0084, respectively (Hofmann et al., 2017; Koren et al., 2019). The fractionation factor for  $\delta^{17}\text{O}$  is calculated using  $\alpha^{17} = (\alpha^{18})^{\lambda_{\text{trans}}}$  with  $\lambda_{\text{trans}} = 0.516$ , assuming relative humidity to be  $75\%$  (Landais et al., 2006). The  $\delta^{17}\text{O}$  and  $\delta^{18}\text{O}$  values of global mean leaf water are then  $-0.136\text{‰}$  and  $-0.131\text{‰}$ , respectively. Thus, the difference between global atmospheric  $\text{CO}_2$  and leaf water is  $\delta^{17}\text{O}_{\text{CO}_2\text{-water}} = 21.666\text{‰}$  and  $\delta^{18}\text{O}_{\text{CO}_2\text{-water}} = 41.631\text{‰}$ . This yields  $\Delta^{17}\text{O}_{\text{CO}_2\text{-water}} = -0.101\text{‰}$ , and this value is indicated as a dashed black line in Fig. 4. The gray shaded area indicates the propagated error using the standard deviation of the relevant parameters in  $180 \times 360$  grid boxes for 12 months of leaf water and  $45 \times 60$  grid boxes for 24 months for  $\text{CO}_2$  (Koren et al., 2019). In Fig. 4b, the intersection between the vertical dashed black line and the discrimination lines for the representative  $c_m/c_a$  ratios of  $\text{C}_3$  and  $\text{C}_4$  plants corresponds to the  $\Delta_A\Delta^{17}\text{O}$  value of  $\text{C}_3$  and  $\text{C}_4$  plants. For  $\text{C}_4$  plants ( $c_m/c_a = 0.3$ ) this yields  $\Delta_A\Delta^{17}\text{O} = -0.3\text{‰}$  (dashed gray line in Fig. 4b), and for  $\text{C}_3$  plants it yields ( $c_m/c_a = 0.7$ )  $\Delta_A\Delta^{17}\text{O} = -0.65\text{‰}$  (dashed black line in Fig. 4b).

Three main factors contribute to the uncertainty of the extrapolated  $\Delta_A\Delta^{17}\text{O}$  value. The first is the measurement error, which contributes  $0.25\text{‰}$  (standard error for individual experiments). The second factor is the uncertainty in the difference between  $\Delta^{17}\text{O}$  of atmospheric  $\text{CO}_2$  and leaf water, and we use results from the global model to estimate an error. For  $\Delta^{17}\text{O}$  of atmospheric  $\text{CO}_2$ , statistics for all  $45 \times 60$  grid boxes for 24 months (2012–2013) show a range of  $-0.218\text{‰}$  to  $-0.151\text{‰}$ , with a mean of  $-0.168\text{‰}$  and a standard deviation of  $0.013\text{‰}$  (Fig. S13). For  $\Delta^{17}\text{O}$  of the leaf water statistics for all  $180 \times 360$  grid boxes for 12 months show a range of  $-0.236\text{‰}$  and  $-0.027\text{‰}$  (Fig. S14). The mean is  $-0.067\text{‰}$  with a standard deviation of  $0.041\text{‰}$ . From the combined errors we estimate the error in  $(\Delta^{17}\text{O}_a - \Delta^{17}\text{O}_{\text{wes}})$  to be  $0.043\text{‰}$ . The third uncertainty in the extrapolation of

**Table 3.** Summary of the parameters used for the extrapolation of leaf-scale experiments to the global scale and the results obtained, as well as an overview of available  $\Delta^{17}\text{O}$  measurements.

$\Delta^{17}\text{O}(\text{CO}_2)$ for CO <sub>2</sub> samples collected in California (USA) (2015)	$-0.177 \pm 0.029 \text{‰}$	Liang et al. (2017b, a)
$\Delta^{17}\text{O}(\text{CO}_2)$ for CO <sub>2</sub> samples collected in Göttingen (Germany) (2010–2012)	$-0.122 \pm 0.065 \text{‰}$	Hofmann et al. (2017)

$\Delta^{17}\text{O}$  comes from the uncertainty in the  $c_m/c_a$  ratio. For C<sub>3</sub> and C<sub>4</sub> plants, these errors are indicated by the light orange and light blue shadings in Fig. 4b.

Taking these uncertainties into account leads to a mean value of  $\Delta_A \Delta^{17}\text{O} = -0.3 \pm 0.18 \text{‰}$  for C<sub>4</sub> plants and  $\Delta_A \Delta^{17}\text{O} = -0.65 \pm 0.18 \text{‰}$  for C<sub>3</sub> plants. The leaf-scale discrimination against  $\Delta^{17}\text{O}$  is then extrapolated to global vegetation using these representative values of  $\Delta_A \Delta^{17}\text{O}$  and the relative fractions of photosynthesis by C<sub>4</sub> and C<sub>3</sub> plants, respectively, as follows:

$$\Delta_A^{17}\text{O}_{\text{global}} = f_{C4} \times \Delta_A^{17}\text{O}_{C4} + f_{C3} \times \Delta_A^{17}\text{O}_{C3}, \quad (8)$$

where  $f_{C4}$  and  $f_{C3}$  are the photosynthesis-weighted global coverage of C<sub>4</sub> and C<sub>3</sub> vegetation.  $\Delta_A \Delta^{17}\text{O}_{C4}$  and  $\Delta_A \Delta^{17}\text{O}_{C3}$  quantify the discrimination against  $\Delta^{17}\text{O}$  by C<sub>4</sub>

and C<sub>3</sub> plants, which are calculated using estimated values of  $c_m/c_a$  from a model. Using assimilation-weighted fractions of 23 % for C<sub>4</sub> and 77 % for C<sub>3</sub> vegetation (Still et al., 2003), the global mean value of  $\Delta_A \Delta^{17}\text{O}$  obtained from Eq. (8) is  $-0.57 \pm 0.14 \text{‰}$ .

Isoflux is the product of isotope composition and gross mass flux of the molecule. In the case of assimilation, the net flux  $F_A = F_{\text{AL}} - F_{\text{LA}}$  is multiplied with the discrimination associated with assimilation (Ciais et al., 1997a).  $F_{\text{LA}}$  and  $F_{\text{AL}}$  are total CO<sub>2</sub> fluxes from leaf to the atmosphere and from atmosphere to leaf, respectively. The global-scale  $\Delta^{17}\text{O}_A$  isoflux is calculated by multiplying the discrimination with the assimilation flux as follows:

$$F_A \times \Delta_A^{17}\text{O} = A \times \left( f_{C4} \times \Delta_A^{17}\text{O}_{C4} + f_{C3} \times \Delta_A^{17}\text{O}_{C3} \right), \quad (9)$$

where  $A = 0.88 \times \text{GPP}$  is the terrestrial assimilation rate. The factor 0.88 accounts for the fraction of  $\text{CO}_2$  released due to autotrophic respiration (Ciais et al., 1997a). The  $\Delta_A \Delta^{17}\text{O}$  isoflux due to photosynthesis is calculated using a GPP value of  $120 \text{ PgC yr}^{-1}$  (Beer et al., 2010) and  $A = 0.88 \times \text{GPP}$ , resulting in an isoflux of  $-60 \pm 15 \text{ } \text{‰} \text{PgC yr}^{-1}$  globally. This is the first global estimate of  $\Delta_A \Delta^{17}\text{O}$  based on direct measurements of the discrimination during assimilation. Our value is in good agreement with previous model estimates. Hofmann et al. (2017) estimated an isoflux ranging from  $-42 \text{ } \text{‰} \text{PgC yr}^{-1}$  to  $-92 \text{ } \text{‰} \text{PgC yr}^{-1}$  (converted to a reference line with  $\lambda = 0.528$ ) using an average  $c_m/c_a$  ratio of 0.7 for both  $\text{C}_4$  and  $\text{C}_3$  plants and  $\Delta^{17}\text{O}$  of  $-0.147 \text{ } \text{‰}$  for atmospheric  $\text{CO}_2$ . A model-estimated value from Hoag et al. (2005) is  $-47 \text{ } \text{‰} \text{PgC yr}^{-1}$  (converted to our reference slope of  $\lambda = 0.528$ ), derived with a more simple model and using  $\Delta^{17}\text{O}$  of  $-0.146 \text{ } \text{‰}$  with  $c_m/c_a$  ratio of 0.33 and 0.66 for  $\text{C}_4$  and  $\text{C}_3$  plants, respectively.

The main uncertainty in the extrapolation of  $\Delta_A \Delta^{17}\text{O}$  from the leaf experiments to the global scale is the uncertainty in the  $c_m/c_a$  ratio. The error from the uncertainty in  $c_m/c_a$  ratio increases when the relative difference in  $\Delta^{17}\text{O}$  between  $\text{CO}_2$  and leaf water increases (Fig. 5b). It is difficult to determine a single representative  $c_m$  value for different plants because this value would need to be properly weighted with temperature, irradiance,  $\text{CO}_2$  mole fraction, and other environmental factors (Flexas et al., 2008, 2012; Shrestha et al., 2019). Recent developments in laser spectroscopy techniques (McManus et al., 2005; Nelson et al., 2008; Tuzson et al., 2008; Kammer et al., 2011) might enable more and easier measurements of  $c_m/c_a$  both in the laboratory and under field conditions. This could lead to a better understanding of variations in the  $c_m/c_a$  ratio among plant species temporally, spatially, and environmentally.

## 6 Conclusions

In order to directly quantify the effect of photosynthetic gas exchange on the  $\Delta^{17}\text{O}$  of atmospheric  $\text{CO}_2$ , gas exchange experiments were carried out in leaf cuvettes using two  $\text{C}_3$  plants (sunflower and ivy) and one  $\text{C}_4$  plant (maize) with isotopically normal and slightly anomalous ( $^{17}\text{O}$ -enriched)  $\text{CO}_2$ . Results for  $^{18}\text{O}$  agree with results reported in the literature previously. Our results for  $\Delta^{17}\text{O}$  confirm that the formalism developed by Farquhar and others for  $\delta^{18}\text{O}$  is also applicable to the evaluation of  $\Delta^{17}\text{O}$ . In particular, our experiments confirm that two parameters determine the effect of photosynthesis on  $\text{CO}_2$ : (1) the  $\Delta^{17}\text{O}$  difference between the incoming  $\text{CO}_2$  and  $\text{CO}_2$  in equilibrium with leaf water and (2) the  $c_m/c_a$  ratio, which determines the degree of back-flux of isotopically exchanged  $\text{CO}_2$  from the mesophyll to the atmosphere. At low  $c_m/c_a$  ratios,  $\Delta_A \Delta^{17}\text{O}$  is mainly influenced by the diffusional fractionation. Under our experimental conditions, the isotopic effect increased with  $c_m/c_a$ ,

e.g.,  $\Delta_A \Delta^{17}\text{O}$  was  $-0.3 \text{ } \text{‰}$  and  $-0.65 \text{ } \text{‰}$  for maize and sunflower with  $c_m/c_a$  ratios of 0.3 and 0.7, respectively. However, experiments with mass independently fractionated  $\text{CO}_2$  demonstrate that the results depend strongly on the  $\Delta^{17}\text{O}$  difference between the incoming  $\text{CO}_2$  and  $\text{CO}_2$  in equilibrium with leaf water. This is supported by calculations with a leaf cuvette model.

$\delta^{18}\text{O}$  is largely affected by kinetic and equilibrium processes between  $\text{CO}_2$  and leaf water, and also leaf water isotopic inhomogeneity and dynamics. The  $\Delta^{17}\text{O}$  variation is much smaller compared to  $\delta^{18}\text{O}$  and is better defined since conventional biogeochemical processes that modify  $\delta^{17}\text{O}$  and  $\delta^{18}\text{O}$  follow a well-defined three-isotope fractionation slope. Results from the leaf exchange experiments were up-scaled to the global atmosphere using modeled values for  $\Delta^{17}\text{O}$  of leaf water and  $\text{CO}_2$ , which results in  $\Delta_A \Delta^{17}\text{O} = -0.57 \pm 0.14 \text{ } \text{‰}$  and a value for the  $\Delta^{17}\text{O}$  isoflux of  $-60 \pm 15 \text{ } \text{‰} \text{PgC yr}^{-1}$ . This is the first study that provides such an estimate based on direct leaf chamber measurements, and the results agree with previous  $\Delta^{17}\text{O}$  calculations. The largest contribution to the uncertainty originates from uncertainty in the  $c_m/c_a$  ratio and the largest contributions to the isoflux come from  $\text{C}_3$  plants, which have both a higher share of the total assimilation and higher discrimination.  $\Delta_A \Delta^{17}\text{O}$  is less sensitive to  $c_m/c_a$  ratios at lower values of  $c_m/c_a$ , for instance for  $\text{C}_4$  plants such as maize.

$\Delta^{17}\text{O}$  of tropospheric  $\text{CO}_2$  is controlled by photosynthetic gas exchange, respiration, soil invasion, and stratospheric influx. The stratospheric flux is well established and the effect of photosynthetic gas exchange can now be quantified more precisely. To untangle the contribution of each component to the  $\Delta^{17}\text{O}$  atmospheric  $\text{CO}_2$ , we recommend measuring the effects of foliage respiration and soil invasion both in the laboratory and at the ecosystem scale.

*Code and data availability.* The data used in this study are included in the paper either with figures or tables. The python code for the cuvette model is available at [https://git.wur.nl/leaf\\_model](https://git.wur.nl/leaf_model) (last access: 23 March 2020, Koren et al., 2020).

*Supplement.* The supplement related to this article is available online at: <https://doi.org/10.5194/bg-17-3903-2020-supplement>.

*Author contributions.* GAA and TR designed the main idea of the study. GAA and TP designed the leaf cuvette setup. TP monitors plant growth. GAA and TR designed the  $\text{CO}_2$  extraction and  $\text{CO}_2$ – $\text{O}_2$  exchange system. GAA conducted all the measurements. GK provided the leaf cuvette model. WP enabled the work within the ASICA project. All authors discussed the results at different steps of the project. GAA and TR prepared the manuscript with contributions from all the co-authors.

*Competing interests.* The authors declare that they have no conflict of interest.

*Acknowledgements.* The authors thank Leonard I. Wassenaar and Stefan Terzer-Wassmuth from the International Atomic and Energy Agency, Vienna, for supplying water standards. The authors thank Eugeni Barkan and Rolf Vieten from the Hebrew University of Jerusalem for calibration of our  $\text{O}_2$  and  $\text{CO}_2$  working gases. We are grateful to Amaelle Landais from Laboratoire des Sciences Du Climat et de l'Environnement Université Paris-Saclay for measuring the  $\Delta^{17}\text{O}$  of leaf water samples for our study. The authors thank Amzad Laskar for the useful discussion during the design of the experiment. This work is funded by the EU ERC project ASICA.

*Financial support.* This research has been supported by the European Research Council (ASICA (grant no. 649087)).

*Review statement.* This paper was edited by Aninda Mazumdar and reviewed by two anonymous referees.
