Summary

The European Commission and the Member States are preparing a harmonised regulation on the presence of 21 1,2-unsaturated pyrrolizidine alkaloids (PAs), together with 14 isomeric PAs, in certain food products, such as herbal teas, herbal infusions, food supplements, and spices, by establishing maximum limits (MLs) for the total concentration of PAs. The proposed EU legislation will not include legal limits for PAs in animal feed. However, it is recommended by European Food Safety Authority to monitor PAs in animal feed for data collection and monitoring purposes.

A research study for the quantitative analysis of PAs in alfalfa and herbal tea was organised by the European Union Reference Laboratory for mycotoxins & plant toxins between April-July 2019. This research study was conducted to obtain a comprehensive overview of the current methods in use by the NRLs, and their capabilities regarding the separation of isomeric groups of PAs. The primary goal was to assess the proficiency of National Reference Laboratories (NRLs). The research study was carried out according to ISO/IEC 17043:2010 [7], however the preparation of the test materials was not part of the WFSR accreditation (R013, Dutch Accreditation Board). During the time that the study was conducted an agreement was reached with the subcontractor for the homogenization of the proficiency test material. The subcontractor has ISO 17043 accreditation for preparation of proficiency test materials.

Twenty-seven laboratories, of which 24 National Reference Laboratories for mycotoxins & plant toxins in food and feed from 22 EU Member States, and 3 Official Laboratories participated in the research study.

Two materials, alfalfa (material A) and herbal tea (material B), were prepared. Material A was prepared by adding a small portion of alfalfa material contaminated with PAs to blank alfalfa material and material B was prepared by adding a small portion of herbal tea material contaminated with PAs to blank herbal tea. Material A contained 24 PAs in concentrations above the LOQ (10 µg/kg), of which 18 PAs will be included in the EU regulation. In material B 17 PAs were present in concentrations above the LOQ, which all will be included in the proposed EU regulation. Both materials were approved for homogeneity.

In this research study the robust mean based on the participants' results was used as consensus value. The consensus value was used as the assigned value. Results were calculated for individual PAs as well as for isomeric groups of PAs. The proficiency of the participants was assessed through z and z' -scores, calculated using the assigned values and a relative target standard deviation of 25%. Proxy z -scores were calculated from non-quantifiable results with a reported LOQ and were considered false negative (FN) when $|\text{proxy } z| \geq 2$. FN scores were included in the evaluation as unsatisfactory results. False positive results (FP) were identified above a threshold value and are evaluated as unsatisfactory results.

As presented in Tables 1a and 1b, the assigned values of individual PAs in material A ranged from 12.0 to 384 µg/kg, the obtained interlaboratory reproducibility (RSD_R) ranged from 13% to 44% and 7 out of the 24 individual PAs had an RSD_R value below or equal to the target standard deviation of 25%. For the sum of 35 PAs for legislation the RSD_R was 32% and for the sum of all PAs it was 25%. 76% of the results for individual PAs were rated with satisfactory z -scores ($|z| \leq 2$), 6% of the results fell into the questionable range with $2 < |z| < 3$ and 18% of the results fell into the unsatisfactory range with $|z| \geq 3$. A total of 31 FN and 19 FP results were reported for material A.

For material B, presented in Tables 1a and 1b, the assigned values of individual PAs ranged from 15.1 to 207 µg/kg, the obtained RSD_R ranged from 13% to 52%, while 9 out of the 17 individual PAs had an RSD_R value below or equal to the target standard deviation of 25%. For the sum of 35 PAs for legislation the RSD_R was 22% and for the sum of all PAs it was 21%. 77% of the results were rated

with satisfactory z-scores ($|z| \leq 2$), 5% of the results fell into the questionable range with $2 < |z| < 3$ and 18% of the results fell into the unsatisfactory range with $|z| \geq 3$. A total of 20 FN and 15 FP results were reported for material B.

For all ten isomeric groups in material A, presented in Tables 1c and 1d, the RSD_R values were above the target standard deviation of 25%. For material B this was the case for one out of six isomeric groups. For the PA isomeric groups in material A, 76% of the results were rated with satisfactory z-scores ($|z| \leq 2$), 12% of the results fell into the questionable range with $2 < |z| < 3$ and 11% of the results fell into the unsatisfactory range with $|z| \geq 3$ and for material B it was respectively, 76%, 8% and 15%. A total of 2 FN was reported for the 10 isomeric groups in material A and 8 FN were reported for the 6 isomeric groups in Material B.

From the results obtained in this research study on pyrrolizidine alkaloids in food and feed the following conclusions can be drawn. With a few exceptions, the limits of quantification reported by the participants are sufficient in view of the proposed legislative limits for PAs. The majority of participants has also included the 21 PAs together with the 14 isomeric PAs in their analytical method. Nevertheless the results indicate that there are a number of issues that need attention and that should be improved. The in many cases relatively high RSD_R values obtained for individual PAs as well as for isomeric groups indicate that there is substantial uncertainty in the assigned values. A high uncertainty indicates that there is a wide variation in the reported results. This is also substantiated by the relatively high number of questionable and unsatisfactory results reported. In this respect, it should be mentioned that the determination of PAs in animal feed and herbal tea is a relatively new area for many NRLs. Furthermore, the wide variety of analytes, including many isomeric compounds, that needs to be covered by the method, requires substantial experience by the laboratory. Efforts need to be made by NRLs to improve the robustness of the implemented methods, in order to produce reliable data. The concept of reporting of isomeric groups needs some special attention as well. It is anticipated that the formalisation of legislation for PAs will stimulate laboratories to optimise their methods and to obtain experience with the analysis of feed and food samples. The progress made will be tested in an upcoming proficiency study, projected for 2022.

1 Introduction

Pyrrolizidine alkaloids (PAs) are secondary plant metabolites produced by a number of plants from the families of Asteraceae (e.g. *Senecio spp.*), Boraginaceae (e.g. *Heliotropium spp.*) and Fabaceae (e.g. *Crotalaria spp.*). PAs occur in plants as free base or the N-oxide (NO). Isomeric forms do occur of several PAs and PA-N-oxides. Many of these PAs have been shown to be highly toxic, causing hepatic veno-occlusive disease (VOD), liver cirrhosis and ultimately death. The European Food Safety Authority (EFSA) has concluded in their opinions [14, 15] that PAs are potentially genotoxic carcinogenic compounds that can have long-term effects on human health even at low doses. PA-containing plants can be present as contaminants in all types of plant-based food and feed materials, including (herbal) teas, herbal food supplements, honey, fodder and feedstuffs. The European Commission (EC) and the Member States (MS) want to protect the health of consumers by regulating the presence of 1,2-unsaturated PAs in certain food products, such as herbal teas, infusions, food supplements, and spices, by establishing maximum limits (MLs) for the total concentration of PAs. The underlying basis for regulation is the assumption that all 1,2-unsaturated PAs have a similar mode of action and similar toxicity (EFSA Scientific Opinion 2011:2406) [3].

Due to practical issues it is not possible to include all known PAs in legislation and it has been proposed by the EC and the MS to base legislation on the presence of 21 PAs that have been identified in the past as the most relevant with respect to occurrence in food products (primarily based on EFSA report 2016:4572 and EFSA Statement 2017:4908). These PAs are presented in Table 2. It should be noted that 4 isomeric PA pairs are included in the original EU list of PAs to be regulated: intermedine and lycopsamine, intermedine-N-oxide and lycopsamine-N-oxide, senecionine and senecivernine and senecionine-N-oxide and senecivernine-N-oxide. In addition to the isomers already in the list, for 10 PA of the 21 PAs, 14 structural isomers have been identified that can co-elute with one or more of the PAs listed 21 PAs (Table 2). If the method used can quantify each isomer, in the proposed legislation these 14 PAs need to be also analyzed and included in the sum concentration together with the 21 PAs of the main list. The proposed legislation is expected to become in effect by 1 July 2022.

Analysis of PAs is typically conducted by liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS), which can be used to determine the sum of the PAs and their isomers or the isomers separately, depending on the chromatographic method applied. In practice no method is capable to chromatographically separate all isomers in a single analysis and (partial) co-elution of isomers will occur. Furthermore, it is known that chromatographic conditions and the brand or type of analytical column can have a great impact on the separation of the different isomeric groups. This can lead for individual compounds to ambiguities in the data evaluation and consequently to uncertainties in the calculation of z-scores for individual laboratories. For this reason, isomeric PAs with the same chemical structure, were in addition assessed as isomeric groups, in which the sum of all individual isomers was considered. One aim of this study is to determine if quantitative results can be compared between methods with different levels of isomer separation.

For animal feeds no legislation is yet foreseen. Based on limited data available for animal feeds it can be expected that the list of relevant PAs may be different from the list relevant for food. For this reason, the analytical methods for animal feeds should preferably also include extra PAs that are not mentioned in the list proposed for legislation in food.

Table 2 PAs proposed for analysis in the research study, a combination of the PAs proposed for EU legislation, their isomers and a set of other PAs.

PA	Isomer 1	Isomer 2	Isomer 3	Isomer 4	Isomeric group
Echimidine (Em)*	Heliosupine (Hs)#				<i>Echimidine group (Em group)</i>
Echimidine-N-oxide (EmNO)	Heliosupine-N-oxide (HsNO)				<i>Echimedine-N-oxide group (EmNO group)</i>
Intermedine (Im)	Lycopsamine (Ly)	Indicine (Id)	Echinatine (En)	Rinderine (Rn)	<i>Intermedine group (Im group)</i>
Intermedine-N-oxide (ImNO)	Lycopsamine-N-oxide (LyNO)	Indicine-N-oxide (IdNO)	Echinatine-N-oxide (EnNO)	Rinderine-N-oxide (RnNO)	<i>Intermedine-N-oxide group (ImNO group)</i>
Retrorsine (Rt)	Usaramine (Us)				<i>Retrorsine group (Rt group)</i>
Retrorsine-N-oxide (RtNO)	Usaramine-N-oxide (UsNO)				<i>Retrorsine-N-oxide group (RtNO group)</i>
Senecionine (Sn)	Senecivernine (Sv)	Integerrimine (Ir)			<i>Senecionine group (Sn group)</i>
Senecionine-N-oxide (SnNO)	Senecivernine-N-oxide (SvNO)	Integerrimine-N-oxide (IrNO)			<i>Senecionine-N-oxide group (SnNO group)</i>
Seneciophylline (Sp)	Spartioidine (St)				<i>Seneciophylline group (Sp group)</i>
Seneciophylline-N-oxide (SpNO)	Spartioidine-N-oxide (StNO)				<i>Seneciophylline-N-oxide group (SpNO group)</i>
Europine (Eu)					
Europine-N-oxide (EuNO)					
Heliotrine (Ht)					
Heliotrine-N-oxide (HtNO)					
Lasiocarpine (Lc)					
Lasiocarpine-N-oxide (LcNO)					
Senkirkine (Sk)					

*in brackets: abbreviation of PA

Proficiency testing is conducted to provide participants with a powerful tool to evaluate and demonstrate the reliability of the data that are produced by the laboratory. Proficiency testing is an important requirement and is demanded by ISO/IEC 17025:2017 [5]. Organisation of proficiency tests (PT) is one of the tasks of European Union Reference Laboratories (EURLs) [6]. Here the primary goal is to assess the proficiency of the National Reference Laboratories (NRLs). In view of the novelty of analyte/matrix combination, this study will be conducted not as a proficiency test but as a 'research study', with the main aim to gain insight in the current capabilities of the NRLs. To facilitate NRLs in their task, official laboratories (OLs) can also participate, in consultation with their NRL.

2 Research study material

2.1 Scope of the research study

This research study focused on pyrrolizidine alkaloids in food and feed, using alfalfa (lucerne) and herbal tea as representative matrices. In view of the relative novelty of this analyte/matrix combination, this study will be conducted as a 'research study' to gain insight in the current capabilities of the participating laboratories to perform analyses on PAs. The scope includes the set of 21 PAs currently considered for legislation in food products. The scope also includes the 14 isomeric PAs that are mentioned for legislation in food products. Furthermore, 9 PAs, erucifoline, erucifoline-N-oxide, jacobine, jacobine-N-oxide, jacoline, jaconine, monocrotaline, monocrotaline-N-oxide and trichodesmine, were included because they can be relevant for feed products as well as of additional relevance for food products.

2.2 Material preparation

For preparation of the two materials A and B, alfalfa (lucerne) and herbal tea, respectively, were used. A mixture (4:1) of blank alfalfa and blank hay and a mixture of several blank herbal teas (mint tea, hibiscus cherry blossom tea, rosemary tea, herbal blend tea) were milled using a centrifugal mill (ZM 200, Retsch, Haan) to obtain a particle size of 500 µm.

Premixes for material A and B were prepared in the following way: PA containing plants (ground to <500 µm), in total 10 g for material A (*Anchusa officinalis* (6 g), *Echium vulgare* (1 g), *Jacobaea vulgaris* (2.5 g) and *Senecio inaequidens* (1 g)) and 3 g for material B (*Senecio vulgaris* (1.5 g) and *Heliotropium europaeum* (1.5 g)), were extracted with, respectively, 200 and 100 mL methanol/water/formic acid (90:10:0.2) in a rotary tumbler for 2 h at RT followed by centrifugation (15 min, 3500g). The extraction was repeated (1 h) with, respectively, 50 and 25 mL of the same extraction solvent. The respective combined extracts were filtered through a glass fiber filter (Whatman GF1A 90 mm) and then slurried with, respectively, 200 g blank material A and 200 g blank material B. 250 mL methanol was added to each premix and mixed for 10 min using a spoon. The premixes were air dried in a fumehood and subsequently homogenized using a Stephan cutter UMC 5.

The final material A was a blend of the fortified alfalfa premix with blank alfalfa and the final material B was a blend of premix herbal tea with blank herbal tea. For both materials, 2300 g of blank material were fortified with 200 g of premix. Materials A and B were homogenised by mixing in a rotating drum during 2 hours and stored at 4 °C until use. The homogenisation of the materials was carried out at Wageningen Evaluating Programs for Analytical Laboratories (WEPAL). WEPAL is accredited to ISO/IEC 17043 for the organisation of proficiency tests by the Dutch Accreditation Council (RvA, R002).

2.3 Sample identification

After homogenization, materials A and B were divided into sub-portions of approximately 25 grams and stored in polypropylene, airtight closed containers in the refrigerator until use.

The samples for the participants were randomly selected and coded using a web application designed for proficiency tests. The code used was 2019/EURL PT MP/PAs/xxx, in which the three-digit number of the code was automatically generated by the WFSR Laboratory Quality Services web application. One sample set was prepared for each participant. Each sample set consisted of one randomly selected sample of material A and one of material B. The codes of the samples for each sample set are shown in Annex 2. The samples for homogeneity and stability testing were also randomly selected out of materials A and B.

2.4 Homogeneity study

To verify the homogeneity of the research materials, ten containers of materials A and B were analysed in duplicate for the PAs.

Method in brief, PAs were extracted from the homogenised sample (2 g) by addition of water containing 0.2% formic acid (40 mL), and shaking in an overhead shaker. After centrifugation of the sample extract, an aliquot (5 mL) was purified using solid phase extraction (SPE) (Phenomenex StrataX, 200 mg/6 ml). The SPE eluate was evaporated to dryness, reconstituted in methanol/water 1/9 (v/v) (500 µL) and filtered. Analysis was done by LC-MS/MS, using reversed phase chromatography under alkaline conditions.

The isomers lycopsamine and indicine could not be separated by the method applied by the organiser of the proficiency test. The presence of indicine can, therefore, not be excluded in material A.

The homogeneity of the materials was assessed according to the International Harmonized Protocol for Proficiency Testing of Analytical Laboratories [10] and ISO 13528:2015 [11]. With this procedure the between-sample standard deviation (s_s) and the within-sample standard deviation (s_w) were compared with the standard deviation for proficiency assessment (σ_p). The method applied for homogeneity testing is considered suitable if $s_w < 0.5 \times \sigma_p$ and a material is considered adequately homogeneous if $s_s < 0.3 \times \sigma_p$. The results of the homogeneity study, grand means with the corresponding RSD_r , are presented in Table 3. The statistical evaluation of materials A and B is presented in Annex 3.

Table 3 Concentrations of pyrrolizidine alkaloids ($\mu\text{g}/\text{kg}$ d.w.) in material A and B obtained during homogeneity testing.

Material A: alfalfa			Material B: herbal tea		
Compound	Conc. ($\mu\text{g}/\text{kg}$)	RSD %	Compound	Conc. ($\mu\text{g}/\text{kg}$)	RSD %
Echimidine	92.1	2.97	Europine	29.6	3.70
Echimidine-N-oxide	397	1.40	Europine N-oxide	226	2.25
Erucifoline	112	2.61	Heliotrine	47.7	2.60
Erucifoline-N-oxide	207	3.27	Heliotrine-N-oxide	397	2.42
Integerrimine	26.9	3.80	Integerrimine	14.0	7.60
Integerrimine-N-oxide	96.6	3.02	Integerrimine-N-oxide	88.8	4.45
Intermedine	41.3	5.07	Lasiocarpine	18.2	3.48
Intermedine-N-oxide	167	9.13	Lasiocarpine-N-oxide	185	2.77
Jacobine	39.8	4.48	Retrorsine	25.4	7.27
Jacobine-N-oxide	34.2	3.90	Retrorsine-N-oxide	124	3.25
Jacoline	42.3	4.19	Senecionine	39.3	4.87
Jaconine	186	2.34	Senecionine-N-oxide	176	3.45
Lycopsamine	93.6	3.27	Seneciphylline	70.9	4.59
Lycopsamine-N-oxide	273	4.94	Seneciphylline-N-oxide	224	3.66
Retrorsine	63.0	3.05	Senecivernine-N-oxide	37.0	8.29
Retrorsine-N-oxide	321	2.53	Spartiodine	14.3	8.21
Senecionine	93.9	2.27	Spartiodine-N-ox	62.6	3.48
Senecionine-N-oxide	213	2.83			
Seneciphylline	90.4	2.49			
Seneciphylline-N-oxide	153	3.83			
Senecivernine	15.4	3.54			
Senecivernine-N-oxide	89.5	4.72			
Senkirkine	12.4	3.85			
Usaramine-N-oxide	76.3	2.81			

Both materials proved to be sufficiently homogeneous for this research study. Senkirkine in material B was the only analyte for which the criteria for homogeneity testing did not comply. A high variability in

the results was obtained, causing s_s (1.72 $\mu\text{g}/\text{kg}$) to exceed the critical value of $0.3\sigma_p$ (1.30 $\mu\text{g}/\text{kg}$) and s_w (6.97 $\mu\text{g}/\text{kg}$) to exceed $0.5\sigma_p$ (2.16 $\mu\text{g}/\text{kg}$).

Senkirkine in material B was found in concentrations ranging from 11 to 38 $\mu\text{g}/\text{kg}$. Likely the high variability of senkirkine in material B is due to the fact that one of the herbal tea ingredients used to prepare the material contained traces of senkirkine as a contaminant. Senkirkine was not present in the extract prepared from the PA-containing plant materials. Despite the deviation for senkirkine, material B was considered to be homogeneous, since the other PAs fulfilled the homogeneity requirements. Senkirkine in material B was excluded from evaluation in this research study.

During the homogeneity testing, it was found that material B contained traces of echinatine, echinatine-N-oxide and rinderine-N-oxide in the range of 0 – 24 $\mu\text{g}/\text{kg}$, with RSDs ranging from 41 – 84%. The average concentration was below the LOQ of 10 $\mu\text{g}/\text{kg}$ used for this study. The presence of these PAs probably resulted from a low contamination in one of the raw materials. Echinatine, echinatine-N-oxide and rinderine-N-oxide in material B were excluded from evaluation in this research study.

2.5 Stability of the materials

The stability of the PAs in the materials was assessed according to [10, 11]. On May 13th, 2019, the day of distribution of the samples, six randomly selected containers of each material A and B were stored at $<-18^\circ\text{C}$. Under these conditions it is assumed that the PAs are stable in the materials. In addition, six samples of each material were stored at $4-6^\circ\text{C}$.

On July 3th, 2019, 51 days after distribution of the samples, for each of the storage conditions ($<-18^\circ\text{C}$ and $4-6^\circ\text{C}$) six samples of materials A and B were analysed in one batch. For each set of test samples, the average of the results and the standard deviation were calculated.

It was determined whether a consequential instability of the analytes had occurred [10,11] in the materials stored at $4-6^\circ\text{C}$. A consequential instability is observed when the average value of an analyte in the samples stored at $4-6^\circ\text{C}$ is more than $0.3\sigma_p$ below the average value of the analyte in the samples stored at $<-18^\circ\text{C}$. If so, the instability has a significant influence on the calculated z-scores.

The results of the stability of materials A and B are presented in Annex 4. Under the tested storage conditions no consequential difference was observed. The PAs in the materials were, therefore, considered stable for the duration of the study.

3 Organisational details

3.1 Participants

This research study focused on the determination of PAs in food and feed, using alfalfa and herbal tea. Invitations to the NRL network were sent out on April 3th, 2019 (Annex 5). Twenty-eight laboratories registered for the study (Annex 1) and 27 participants reported their results. One participant was unable to report results due to problems with their method. Of the participating laboratories, 24 were NRLs and three were OLs. Each participant was free to use their analytical method of choice reflecting their routine procedure. The participants were asked to report the results through a web application designed for proficiency tests as well as to fill out a questionnaire, where they were asked to provide detailed information on the analytical method used for detection and quantification of PAs (extraction solvent/procedure, clean-up, detection technique, limit of detection and limit of quantification).

3.2 Material distribution and instructions

Each participant received a randomly assigned laboratory code, generated by the web application. The sample sets with the corresponding numbers, consisting of two coded samples (Annex 2) and three vials containing a total of 45 PA standards, including all the relevant PAs and isomers proposed for legislation, were sent to the participants on May 13th, 2019. The sample sets were dispatched immediately by courier to the participants in insulation boxes containing dry-ice. The participants were asked to store the samples at 4-6°C, the standard solutions at <-18°C, and to analyse the samples according to their routine method. As reported by participants, all parcels were received in good order within 24 hours after dispatch.

The samples were accompanied by a letter describing the requested analysis (Annex 6) and an acknowledgement of receipt form. In addition, by e-mail, each participant received instructions on how to use the web application to report the results. The questionnaire was intended to collect additional information on LOQs, method recovery estimates (%) and other method-related aspects (e.g. extraction and clean-up, chromatographic and detection conditions, calibration strategy) to investigate individual and/or general patterns on the submitted results.

A single analysis result for each PA in each sample was requested. The deadline for submitting the quantitative results was June 24th, 2019, allowing the participants six weeks for analysis of the test samples.

4 Evaluation of results

The statistical evaluation was carried out according to the International Harmonized Protocol for the Proficiency Testing of Analytical Laboratories [10], elaborated by ISO, IUPAC and AOAC and ISO 13528:2015 [11] in combination with the insights published by the Analytical Methods Committee [12, 13] regarding robust statistics.

The evaluation is based on assigned values and the standard deviation for proficiency assessment (σ_p). From this, z-scores are calculated to classify the participants' performance. Details on the methods used for the statistical evaluation can be found in the background document 'EURL-MP PT performance assessment' [14] on the EURL mycotoxins & plant toxins (EURL-MP) website.

4.1 Calculation of the assigned value

The robust mean was used as consensus value in this research study. The consensus value based on the participants' results (NRLs and OLs) was used as the assigned value. The values and their uncertainties are summarised in Table 1 in the Summary section. Assigned values were established for all analytes in both materials, except for senecivernine in material B (herbal tea) since the uncertainty of the assigned value, 3.56 $\mu\text{g}/\text{kg}$, exceeds $0.7 \sigma_p$ (1.88 $\mu\text{g}/\text{kg}$).

4.2 Standard deviation for proficiency assessment (σ_p)

A fixed relative target standard deviation for proficiency assessment of 25% was used, irrespective of the plant toxin, matrix or concentration. This generic fit-for-purpose value is considered to reflect current analytical capabilities and best practises for mycotoxin and plant toxin determination in food and feed. The rationale behind this is provided in the background document 'EURL-MP PT performance assessment' on the EURL-MP website [4].

4.3 Quantitative performance (z-scores)

For evaluation of numerical results submitted by the participant, z-scores are calculated based on the assigned value, its uncertainty, and the standard deviation for proficiency assessment. When the uncertainty of the assigned value is negligible and no instability of the analytes in the material is observed, z-scores are calculated by:

$$Z = \frac{x-C}{\sigma_p} \quad \text{Equation 1}$$

where:

- z = z-score;
- x = the result of the laboratory;
- C = assigned value, here the consensus value;
- σ_p = standard deviation for proficiency assessment.

The z-score compares the participants' deviation from the assigned value, taking the target standard deviation accepted for the proficiency test into account, and is interpreted as indicated in Table 4.

Table 4 Classification of z-scores.

$ z \leq 2$	Satisfactory
$2 < z < 3$	Questionable
$ z \geq 3$	Unsatisfactory

If the uncertainty of the assigned value and, if applicable, instability of the analyte in the research material, is not negligible, then this is taken into account in the determination of the z-score. If applicable, this is indicated by assigning a z' -, z_i -, or z'_i -score. For details see the background document 'EURL-MP PT performance assessment' on the EURL-MP website [4].

In this research study, the uncertainty of the assigned value for individual pyrrolizidine alkaloids in both materials A and B were not negligible and this was taken into account in the assignment of the z-score (z'):

- material A: echimidine-N-oxide, intermedine, intermedine-N-oxide, lycopsamine-N-oxide, retrorsine, retrorsine-N-oxide, usaramine-N-oxide, senecivernine, intergerrimine, senecionine-N-oxide, senecivernine-N-oxide, seneciphylline, seneciphylline-N-oxide and erucifoline-N-oxide and jacobine.
- material B: retrorsine, senecionine, senecionine-N-oxide, senecivernine-N-oxide, integerrimine-N-oxide, seneciphylline, spartioidine, lasiocarpine and lasiocarpine-N-oxide.

For the isomeric groups, the uncertainty of the assigned value in both materials, except for the echimidine group in material A and the retrorsine group, retrorsine-N-oxide group and seneciphylline-N-oxide group in material B, were not negligible and this was taken into account in the assignment of the z-score (z').

For the summed results of the 35 PAs for legislation in material A, the uncertainty of the assigned value was taken into account for in assignment of the z-score (z').

In all other cases, the uncertainty of the assigned value was negligible.

4.4 Evaluation of non-quantified results

In cases, where participant(s) reported: '<[value]'; or 'not detected (nd)' (i.e. below their limit of quantification (LOQ)), 'proxy-z-scores' were calculated to assess possible false negatives and to benchmark the LOQ relative to the assigned value and the LOQ of the other participants.

A proxy-z-score was calculated by using Equation IV and Equation V of the background document 'EURL-MP-background doc_001' (for details see the EURL-MP website) [14], using the reported LOQ value as a result. Proxy-z-scores are for information only and indicated as a value between brackets. Values ($z < -2$) are considered as False Negatives (see 4.5). Values ($z > 2$) indicate that the LOQ is high in relation to the assigned value and high in comparison to other participants.

Other types of reported results, e.g. 'detected' or 'not detected', without specification of LOQ, were excluded from the evaluation. In these cases, the participant was considered to have no quantitative method available for the applicable analyte/matrix.

4.5 False positive and false negative results

A false positive is a quantitative result reported by the participant while the analyte is not detected in the research material by the organiser, and/or not detected by the majority of the other participants. A threshold is then applied, above which results are considered false positives, indicated as '**FP**'. False positives are to be interpreted as unsatisfactory performance.

Specific for this research study:

- Considering the fact that the proposed legislation requires a limit of quantification (LOQ) of 10 µg/kg, it was decided to use a threshold limit of 2×LOQ, in this study 20 µg/kg, to determine FP.
- The analytical method applied by the organiser of the research study did not allow to determine the presence of (trace amounts) of indicine due to co-elution of indicine with lycopsamine. Therefore, in material A, no FP were considered for indicine.
- Two participants reported for material B the sum of intermedine-N-oxide and indicine-N-oxide above the threshold value. In both cases, one of the two PAs was indicated as FP.
- The PAs echinatine, echinatine-N-oxide and rinderine-N-oxide were detected in material B in trace amounts close to the LOQ by the organiser of the research study (paragraph 2.4). It was decided that quantification of these PAs by the participants was possible. These PAs were, therefore, not considered as FP in material B.

When an PA is present in the material, i.e. an assigned value has been established, and the participant reports the analyte as '<[value]', or 'not detected', an assessment is made to judge whether such results should be classified as a false negative. This is the case when the proxy-z-score (see 4.4) is <-2. False negatives are indicated as '**FN**'. False negatives are to be interpreted as unsatisfactory performance.

5 Assessment of participants' performance

5.1 Scope and LOQ

This research study was dedicated to the quantification of pyrrolizidine alkaloids in alfalfa and herbal tea samples. Annex 7 summarises the quantitative scopes of each participant, with an indication of the LOQs for each PA.

Twenty-five participants analysed the two samples, material A and material B for 44 PAs. Participant PT9566 analysed only material A and participant PT9569 analysed only material B.

Concerning the individual PAs included in the scope of the participants: 24 participants did have methods for determination of the 21 PAs first considered for legislation, two participants did not have echimidine and echimidine-N-oxide in their scope and one laboratory did not have europine, europine-N-oxide and heliotrine-N-oxide in its scope.

Participant PT9570 included only 4 PAs, retrorsine, senecionine, seneciphylline and senkirkine, in the method. The results submitted by participant PT9570 were not included in the calculation of the assigned value. For participant PT9570 z-scores were calculated separately for these four PAs using the assigned values calculated from the data submitted by the other participants.

Of the 27 participants, 18 participants also had all 14 isomeric analogues of the 21 PAs considered for legislation in their scope. Nineteen participants also included nine additional PAs in their scope, which are known to occur in food and feed products.

Several results were reported as 'detected'. In case the participant had specified an LOQ (Annex 7), for these results proxy z-scores were calculated. Also a few results were reported as 'nd' without specification of LOQ and therefore, these results were excluded from evaluation (see section 4.4).

With respect to the LOQs provided by the participants, 12 participants reported an LOQ of 10 µg/kg for all analytes, seven participants reported LOQs in the range of 2 – 5 µg/kg, four participants reported variable LOQs in the range of 0.1 – 10 µg/kg and two reported LOQs in the range of 20 – 25 µg/kg. One laboratory reported LOQs in a wider range, namely 3 - 400 µg/kg and one laboratory provided no LOQs. It can be concluded that most participants are able to achieve LOQs of 10 µg/kg or lower, which is in line with the requirements of the proposed legislation.

5.2 Analytical methods

All participating laboratories were asked to fill in a questionnaire addressing their accreditation, conditions used for sample preparation, chromatographic separation, detection, quantification and calibration. One participant provided no information on their accreditation, nor any method details and the preparation conditions. An overview of the applied methods is presented in Annex 8.

Out of 26 laboratories, four had their analytical method covered by ISO 17025 accreditation, while 21 participants had not accredited their method and one participant did not provide this information.

The information provided about test material preparation showed that the most often reported intake was 2 g (88%) in combination with 40 ml extraction solvent (among which four participants did a double extraction 2×20 ml) and one laboratory used 8 ml. Two participants used 1 g of which one in combination with 20 ml of extraction solvent and one with a double extraction of 15 ml and 10 ml. One laboratory used 2.5 g with 25 ml extraction solvent. The extraction time was in most of the cases

30 min and in case of a double extraction 2×15 min. As extraction solvent participants often used an aqueous acidic solvent: 0.2% formic acid (14×), 1-2% formic acid (3×), or 0.05 M sulphuric acid (7×). One participant used a mixture of methanol and water and in one case a solution containing sodium chloride and hydrochloric acid was used.

SPE was used by 23 participants for sample extract purification. Three participants used no clean-up among which two participants only diluted the extract. The following clean-up cartridges were reported: polymeric SPE sorbent (Stata X or Oasis HLB, 14×), Bond Elut (3×), DSC (4×), SDB (1×) and Evolute express CX (1×).

All participants used LC in combination with MS for separation and identification of the PAs. Three participants used two different methods, so in total 30 methods were reported. Acetonitrile was used as organic mobile phase modifier by 18 while 12 participants used methanol. The majority of participants (67%) indicated that acidic chromatography had been used. For the preparation of the acidic mobile phase the following buffers were used: formate (formic acid with or w/o ammonium formate) (15×), acetate (acetic acid with or w/o acetate) (4×) and acetate (acetic acid with ammonium hydroxide) (1×). Ten participants employed an alkaline mobile phase with ammonium carbonate (33%).

For the acidic chromatography a wide variety of column brands were used, mostly with a C18 type stationary phase (85%). Columns from different suppliers were used: Waters Acquity BEH C18 (5×); Thermo Scientific Hypersil Gold (5×); Phenomenex Gemini (2×), Luna (2×) and Kinetex XB (1×); Agilent Portoshell SB (1×) and Zorbax SB (1×). A few methods used a different stationary phase: Phenomenex Kinetex biphenyl or phenyl-hexyl (3×). For chromatography with alkaline conditions participants also used mostly C18 type stationary phases, mostly from one supplier: Waters Acquity BEH C18 (8×), Atlantis T3 (1×) and XSelect CSH C18 (1×). There was a considerable variation in column length, between 50 and 200 mm, although typically 150 mm was used (18×). The total run time reported varied between 9 and 70 min, typically around 15 min (13×). Most participants used Very-High Pressure Liquid Chromatography (VHPLC) type columns with a small internal diameter, around 2 mm (25×), and sub-2-µm particle size (17×).

For the identification and quantification of the PAs most participants used LC-MS/MS (93%), two participants applied LC-HRMS (High resolution Mass Spectrometry) of which one participant used Quadrupole Time-of-Flight (QTOF)/MS.

On questions about the calibration approach all except two participants replied. For the quantification of the PAs 20 participants used multi-level standard addition (MLSA), among which seven used matrix-matched standard calibration, four used standard addition after extraction, six used standard addition before extraction and one participant used solvent external standard calibration. Eight participants used for quantification single point calibration, among which seven used standard addition before extraction and one after extraction.

Based on the results and method details provided by the participants no obvious effects of extraction or clean-up on the results were observed but the results indicated that subtle changes in chromatographic conditions may already result in differences in the separations obtained by the individual methods. The different stationary phase brands and types also have a significant effect on the separation of isomers and the order of elution may also differ. Because the effect of the chromatography on the separation of isomers is an important issue with respect to the adequate quantification of PAs, this was investigated in more detail. The participants were asked to analyse the three provided mixtures of standards and to report the retention times (Annex 8). First, it is important to state that to date no analytical methods have been described that can separate all the isomeric groups of Table 2 in a single run with baseline separation with the current state-of-the-art chromatographic instrumentation. It is however well established that separation of isomers can be influenced by the choice of column bonded phase material as well as the pH of the mobile phase. In Table 5 an overview is given of the main separation problems encountered by the different chromatographic methods. From the data it follows that there are frequent difficulties with the separation of isomeric pairs or groups when acidic chromatography is used. For the (smaller group of)

alkaline chromatography the problem seems to be somewhat more limited. Overlooking all methods and datasets, for almost all isomeric pairs and groups problems with (partial) co-elution can be identified. Only for the echimidine N-oxide/heliosupine N-oxide pair no problems with separation have been identified, but for all the other possible isomer combinations, at least one but often more participants reported poor separation.

Table 5 General evaluation of problems with separation between isomeric compounds based on the information provided by the participants.

PA isomeric group	Acidic chromatography		Alkaline chromatography	
	Frequent problem	Less frequent problem	Frequent problem	Less frequent problem

5.3 Performance

The twenty-seven participants were asked to determine and quantify as many individual PAs as possible in the two materials. All participants received analytical standards of 44 PAs.

- Since material A contained 24 and material B 17 PAs above the LOQ (10 µg/kg), the maximum number of quantifiable **individual PAs** was 41.
- In material A, data for quantification of 10 isomeric groups could be submitted and for 6 isomeric groups in material B, amounting to a total of 16 **isomeric groups**.
- For each of the two materials, all submitted data for the 35 individual PAs and isomers proposed for legislation were summed. This sum includes, besides the compounds for which a z-score was evaluated, also quantitative results for individual PAs for which a z-score could not be calculated, trace amounts and **FP** results. The data were used to calculate the z-score for the **sum of 35 PAs for legislation** in each material.
- For each of the two materials, all submitted data for all 44 individual PAs also were summed. These data were used to calculate the **sum of total PAs** z-scores for materials A and B. Since some participants reported individual PAs belonging to the group of 'other PA' in material B, the z-score for 'total sum' differs slightly from the z-score for 'sum of 35 PAs for legislation'.
- Reporting of **FN** and **FP** results was also evaluated.

The quantitative performance was assessed through z-scores. For each participant, the results of the calculated individual z-scores for the PAs in material A (alfalfa) and B (herbal tea) are summarised in Annex 9 and Annex 10, respectively. These annexes also show graphical representations of the z-scores per individual PA (41) and the sixteen isomeric groups. Results per group were calculated based on the reported data for the individual isomers. For laboratories that had problems with separation between PA isomers, only z-scores were calculated for the total PA concentrations of each isomer group. A summary of the performance of the participants in this research study is provided in Annex 11.

A summary of the statistical evaluation of the research study results is presented in Tables 6 to 9. These tables include all relevant parameters: the assigned value (A), the uncertainty of the assigned value (u), the standard deviation for proficiency assessment (σ_p) and the robust (relative) standard

deviation, based on participants' results. In case the uncertainty of the assigned value did not comply with the criterion $u > 0.3\sigma_p$, the uncertainty of the assigned value was taken into account in the evaluation of the z-scores (calculating the z'-score).

A total of 61 z-/z'-scores, 24 z-scores and 37 z'-scores were calculated from the reported data for both materials.

S z-scores: satisfactory z-scores

For the individual PAs in material A, 76% of the results were rated with satisfactory z-scores ($|z| \leq 2$), 6% of the results fell into the questionable range with $2 < |z| < 3$ and 18% of the results fell into the unsatisfactory range with $|z| \geq 3$ (Table 6). For the isomeric groups in material A was this respectively 76%, 12% and 11% (Table 7).

For the individual PAs in material B, 77% of the results were rated with satisfactory z-scores ($|z| \leq 2$), 5% of the results fell into the questionable range with $2 < |z| < 3$ and 18% of the results fell into the unsatisfactory range with $|z| \geq 3$. For the isomeric groups in material B was this respectively 76%, 8% and 15%.

In case of the total sum of the 35 PAs considered for legislation, for material A, 76% of submitted results were satisfactory and for material B 80%. In case of the total sum of the PAs, for both materials, 80% of submitted results were satisfactory.

In Annex 11 an overview of the overall performance for each participant in this research study is summarized. For the two materials combined, a maximum of 40 satisfactory z-scores for the individual PAs could be obtained, and '41 out of 41' therefore reflects an optimal performance in terms of scope and capability for quantitative determination. Out of 27 participants, none of the participants showed optimal performance by detecting all individual PAs with correct quantification, the absence of false positive and false negative results. In case of the isomeric groups, a maximum of 16 satisfactory z-scores for the individual PAs could be obtained, and '16 out of 16' therefore reflects an optimal performance in terms of scope and capability for quantitative determination. Five of 27, showed satisfactory performance. With respect to the total sum of PAs considered for legislation, 19 participants, and in case of the total sum, 17 participants showed satisfactory performance.

A total of 19 FP results was reported by participants for material A. Six FP results concerned heliosupine N-oxide, in the range of 21.3 to 35 µg/kg. Heliosupine was reported twice (64 and 70.9 µg/kg). Indicine-N-oxide was reported two times (100 and 161 µg/kg) and one participant reported the presence of echinatine-N-oxide and rinderine-N-oxide (565 and 656 µg/kg). Usaramine was reported three times (73.4, 120 and 164.3 µg/kg). One participant reported spartioidine (63 µg/kg) and two participants spartioidine-N-oxide (90 and 405 µg/kg). Europine-N-oxide (243 µg/kg) was reported by one participant.

For material B 15 FP results were reported. One participant reported the presence of lycopsamine (139.4 µg/kg), one participant reported indicine (22.2 µg/kg) and one reported rinderine (25.5 µg/kg). Two participants reported intermedine-N-oxide (35.1 and 38.8 µg/kg) and one reported indicine-N-oxide (30 µg/kg). Usaramine was reported three times (53.7, 54.6 and 120 µg/kg) and

usaramine-N-oxide two times (85.5 and 150 µg/kg). Senecivernine was reported two times (28.1 and 31.6 µg/kg as well as jacobine (26 and 50 µg/kg).

The reported FPs can in part be attributed to the fact that participants experienced difficulties with the correct identification of individual compounds of isomeric groups (e.g. heliosupine, heliosupine-N-oxide, indicine-N-oxide, usaramine, spartioidine and spartioidine-N-oxide in material A and usaramine, usaramine-N-oxide and senecivernine in material B). A number of participants indicated that they had very limited experience with the inclusion of the 14 PA isomers in their method.

A total of 31 false negative (FN) results was reported for material A. With respect to the regulated PAs, three FNs were reported for integerrimine and two for usaramine-N-oxide. Single FN results were reported for echimidine-N-oxide, intermedine, lycopsamine, intermedine-N-oxide, retrorsine-N-oxide, usaramine-N-oxide, senecionine, senecivernine, senecionine-N-oxide, senecivernine-N-oxide and integerrimine. For the additional, non-regulated, PAs, six FNs were reported for jacobine, three for jacobine-N-oxide and erucifoline-N-oxide, two for jacoline and one FN result for erucifoline and jaconine.

For material B 19 FN results were reported: three FNs for retrorsine, senecionine and senecivernine-N-oxide, two FNs for spartioidine-N-oxide and lasiocarpine-N-oxide and one FN for senecionine-N-oxide, integerrimine-N-oxide, seneciophylline, europine, europine-N-oxide, heliotrine and heliotrine-N-oxide.

With respect to the isomeric groups, for material A in two cases, the echimidine-N-oxide group and the retrorsine-N-oxide group, one participant reported a FN. For material B eight FNs were reported for the following isomeric groups: three FNs for the retrorsine group and the senecionine group and one FN for the senecionine-N-oxide and the seneciophylline group.

To some extent the reported FNs for the additional PAs in material A can be due to inexperience of participants to monitor for these PAs. The concentrations of the six PAs (erucifoline, erucifoline-N-oxide, jacobine, jacobine-N-oxide, jacoline and jaconine) in material A ranged from 33 to 192 µg/kg and were well above the LOQs reported by the majority of participants. Only in three instances the reported FN can be correlated to a reported LOQ > 10 µg/kg.

The (possible) coelution and reporting of isomeric PAs showed to be a complex issue for a number of participants. Many different combinations of co-eluting isomers were reported (Table 5, Annex 8, 9, 10). A number of participants correctly indicated which isomers were reported as a sum result. However, some participants reported contradictory results. Double reporting of isomers may have occurred in a number of these cases, resulting in a too high isomeric group total concentration. In cases where double reporting was evident (exact the same concentration for two co-eluting isomers), only one of the results was used for the calculation of the isomeric group total concentration. However, double reporting could not always be verified, e.g. in case a participant reported two slightly different concentrations for two coeluting isomers. Unfortunately, the participants had not been asked to report isomeric group concentrations. The calculation of the isomeric group totals was now done by the study organiser based on the provided results. Asking the participants to report isomeric group totals together with the results for individual isomers, could possibly have prevented or reduced the risk of including double reporting in the group totals.

The option of reporting isomeric groups instead of reporting all compounds individually was evaluated. The concept of reporting isomeric groups is introduced to address the differences between methods with respect to the separation of isomers. The idea is that in case isomers are not (fully) separated the sum of the isomers can still be determined. A representative standard is used to quantify those isomers that have similar properties with respect to fragmentation and sensitivity. E.g. lycopsamine has very similar mass spectrometric properties as intermedine and can therefore be quantified by using intermedine (or vice versa). Care should be taken with isomers that have different fragmentation properties such as echimidine and heliosupine. In these cases it is highly preferred when the isomers are chromatographically separated and quantified individually. In the two materials in total 16 isomeric groups and 28 different PAs were present for which z-scores could be assigned (Tables 6-9). The percentage satisfactory z-scores for the isomeric groups varied between 67 and

92%, with an average of 76%. This is comparable with the satisfactory z-scores for the individual PAs present in the materials (range 53-92%, average 78%). The results indicate that there is a relatively strong link between the results for the individual PAs in an isomeric group and the sum of the isomers. This is not really surprising because for many isomeric groups only one isomer was present, or one isomer was dominating. For the more complex groups (intermediate and senecionine groups and corresponding N-oxides), this correlation was somewhat weaker, likely due to the increased number of possibilities that could result in a satisfactory or unsatisfactory result. Furthermore, in the total group concentration, theoretically an unsatisfactory low concentration for one isomer can be compensated by an unsatisfactory high concentration of another isomer, resulting in an overall higher satisfactory rate. This compensatory effect is not evident from the data. Rather the opposite is found: for the four groups mentioned above the satisfactory rate for the 14 individual compounds is 77% (range 53-88%), while for the four groups it is only 73% (range 68-75%). The reporting as isomeric groups may therefore need some more attention.

5.4 Robust relative standard deviation

The robust standard deviation (RSD_R) was calculated according to ISO13528:2015 [12] for informative purposes only. This provides a good estimation of the interlaboratory variability. The RSD_R values for each PA in both materials are shown in Annex 9, 10, in the Tables 6 to 9 and also in Table 1 (Summary section).

For material A, the robust standard deviations (RSD_R) of the reported results (ranging between 14-44%), were below the target standard deviation (25%) for eight out of 24 individual PAs. For the isomeric groups in material A, none of the RSD_R (ranging between 28-51%) were below the target standard deviation. For material B, for the individual PAs, nine out of 17 RSD_R (ranging between 13-52%) were below the target standard deviation (25%). For the isomeric groups in material B, two out of six RSD_R (ranging between 24-44%) were below the target standard deviation.

The RSD_R values for the total sum of 35 PAs considered for legislation was for material A 32%, which is above the target standard deviation (25%) and for material B it was 25%. The RSD_R values for the total sum of PAs was below the target standard deviation (25%) for material A (22%) as well as for material B (21%).

6 Conclusions

Twenty-seven laboratories, of which 24 NRLs for mycotoxins and plant toxins in food and feed from 22 EU Member States, and 3 OLs participated in the research study EURL-PT-MP02 on the quantitative determination of PAs in alfalfa and herbal tea.

Two materials, alfalfa (material A) and herbal tea (material B), were prepared. Material A was prepared by adding blank alfalfa to alfalfa material contaminated with PAs and material B was prepared by adding blank herbal tea to herbal tea material contaminated with PAs. Material B contained only PAs from the list that will be regulated, and material A contained PAs that will be regulated as well as PAs that are not included in the list of regulated PAs.

Fifteen out of 27 participants determined all 44 PAs and 24 participants determined the 35 PAs considered for legislation. LOQs varied widely from 0.1 µg/kg to 250 µg/kg. Twenty-two participants reported LOQs equal or lower than 10 µg/kg, which is the minimally required LOQ specified in the upcoming legislation.

Most of the participants used methods based on LC-MS/MS (93%) with SPE clean-up (85%).

In this research study the robust mean was used as consensus value. The consensus value based on the participants' results was used as the assigned value. Results were calculated for individual PAs as well as for isomeric groups of PAs. The assigned values of individual PAs in material A ranged from 12.0 to 384 µg/kg and in material B from 15.1 to 207 µg/kg. Obtained interlaboratory reproducibility (RSD_R) ranged from 13% to 52%. For material A, RSD_R values were below the target standard deviation (25%) for seven out of 24 individual PAs and for material B this was the case for nine out of 17 individual PAs.

For the isomeric groups in material A, RSD_R values were below the target standard deviation (25%) for none of ten isomeric PA groups and for material B this was the case for three out of six groups of PA isomers. For the sum of 35 PAs considered for legislation the RSD_R was 32% and 25% for material A and B, respectively and for the sum of total PAs 25% and 21% for material A and B, respectively.

The proficiency of the participants was assessed through z-scores, calculated using the assigned values and a relative target standard deviation of 25%. For material A, 76% of the results for individual PAs were rated with satisfactory z-scores ($|z| \leq 2$), 6% of the results fell into the questionable range with $2 < |z| < 3$ and 18% of the results fell into the unsatisfactory range with $|z| \geq 3$. For material B 77% of the results were rated with satisfactory z-scores ($|z| \leq 2$), 5% of the results fell into the questionable range with $2 < |z| < 3$ and 18% of the results fell into the unsatisfactory range with $|z| \geq 3$. For the PA isomeric groups in material A, 76% of the results were rated with satisfactory z-scores ($|z| \leq 2$), 12% of the results fell into the questionable range with $2 < |z| < 3$ and 11% of the results fell into the unsatisfactory range with $|z| \geq 3$ and for material B it was respectively, 76%, 8% and 15%.

A total of 19 FP results was reported by participants for material A and 15 FP were reported for material B. The reported false positives can in part be attributed to the fact that participants experienced difficulties with the correct identification of individual compounds of isomeric groups (e.g. heliosupine, heliosupine-N-oxide, indicine-N-oxide, usaramine, spartioidine and spartioidine-N-oxide in material A and usaramine, usaramine-N-oxide and senecivernine in material B).

A total of 31 FN results was reported for material A, while for material B 19 FN results were reported. With respect to the isomeric groups, for material A two FNs were reported and for material B there were eight FNs. Sixteen FNs in material A concerned the non-regulated, additional PAs of interest for analysis of feed. Only three FN results could be correlated to a reported LOQ > 10 µg/kg.

The (possible) coelution and reporting of isomeric PAs showed to be a complex issue for a number of participants. Many different combinations of co-eluting isomers were reported. A number of participants correctly indicated which isomers were reported as a sum result. However, some participants reported contradictory results. Double reporting of isomers may have occurred in a number of cases, resulting in a too high isomeric group total concentration. Unfortunately, the participants had not been asked to report isomeric group concentrations. The calculation of the isomeric group totals was now done by the study organiser based on the provided results. Asking the participants to report isomeric group totals together with the results for individual isomers, could possibly have prevented or reduced the risk of including double reporting in the group totals.

From the results obtained in this research study on PAs in food and feed the following conclusions can be drawn. With a few exceptions, the limits of quantification reported by the participants are sufficient in view of the proposed legislative limits for PAs. The majority of participants has also included the 21 PAs together with the 14 isomeric PAs in their analytical method. Nevertheless the results indicate that there are a number of issues that need attention and that should be improved. The in many cases relatively high RSD_R values obtained for individual PAs as well as for isomeric groups indicate that there is substantial uncertainty in the assigned values. A high uncertainty indicates that there is a wide variation in the reported results. This is also substantiated by the relatively high number of questionable and unsatisfactory results reported. In this respect, it should be mentioned that the determination of PAs in animal feed and herbal tea is a relatively new area for many NRLs. Furthermore, the wide variety of analytes, including many isomeric compounds, that needs to be covered by the method, requires substantial experience by the laboratory. Efforts need to be made by NRLs to improve the robustness of the implemented methods, in order to produce reliable data. The concept of reporting of isomeric groups needs some special attention as well. It is anticipated that the formalisation of legislation for PAs will stimulate laboratories to optimise their methods and to obtain experience with the analysis of feed and food samples. The progress made will be tested in an upcoming proficiency study, projected for 2022.

Annex 5 Invitation letter

P.O. Box 230 | 6700 AE WAGENINGEN | The Netherlands

Dear colleague,

The EURL mycotoxins & plant toxins will organize a Research Study regarding pyrrolizidine alkaloids in food and feed matrices. This study will be organised according to ISO 17043 (General requirements for proficiency testing - R013), except the preparation of the test materials. The study will focus on the quantification of pyrrolizidine alkaloids. Harmonised EU regulation for pyrrolizidine alkaloids in these matrices is being prepared and their inclusion in national monitoring is recommended by EFSA. In view of the relative novelty of this analyte/matrix combination, this study will be conducted as a 'Research Study' to gain insight in the current capabilities of the NRLs. The scope includes the set of 21 PAs currently considered for legislation in food products. The scope also includes 14 PAs that are isomeric analogues of the PAs considered for legislation as well as 13 PAs that can be of additional relevance for food and feed. The EURL mycotoxins & plant toxins will evaluate the results of the research study in the same way as a proficiency test, ensuring an appropriate follow-up and informing the Commission and the Member States of the results. The primary goal of this research study is to give laboratories the opportunity to evaluate or demonstrate their performance regarding the analysis of these compounds in food and feed matrices. A secondary goal of this study is to evaluate the capabilities of laboratories to discriminate between PAs considered for legislation and PAs not considered for legislation.

According to Regulation (EU) 2017/625 all EU National Reference Laboratories (NRLs) plant toxins in food and/or feed are strongly encouraged to participate. I would like to invite you to participate in this test.

1. Test materials

- One herbal tea and one alfalfa (lucerne) material will be supplied.
- The test amount sent will be approximately 25 g.
- Test materials will be sent in April/May 2019. The distribution of the test materials will be announced by e-mail. The deadline for reporting will be six weeks after the shipment of the samples.

2. Scope of analysis

- The materials may contain one or more of the following analytes, included in the list of 21 PAs considered for legislation:
 - Echimidine and echimidine-N-oxide
 - Europine and europine-N-oxide
 - Heliotrine and heliotrine-N-oxide

RIKILT

DATE
April 3, 2019

SUBJECT
Research study for
pyrrolizidine alkaloids in food
and feed matrices

pt.rikilt@wur.nl

Wageningen Research
Foundation/RIKILT is part of
Wageningen University & Research.
RIKILT carries out research into the
safety and reliability of food and
feed. RIKILT is ISO 17025 and ISO
17043 accredited (the accredited
tests are described on www.vla.nl
(no. L014 and R013).

- Intermedine and intermedine-N-oxide
 - Lasiocarpine and lasiocarpine-N-oxide
 - Lycopsamine and lycopsamine-N-oxide
 - Retrorsine and retrorsine-N-oxide
 - Senecionine and senecionine-N-oxide
 - Seneciphylline and seneciphylline-N-oxide
 - Senecivernine and senecivernine-N-oxide
 - Senkirkine
- The materials may also contain one or more of the following analytes, which are isomeric analogues of the PAs included in the list of 21 PAs considered for legislation:
 - Echinatine and echinatine-N-oxide
 - Heliosupine and heliosupine-N-oxide
 - Indicine and indicine-N-oxide
 - Integenimine and integenimine-N-oxide
 - Rinderine and rinderine-N-oxide
 - Spartioidine and spartioidine-N-oxide
 - Usaramine and usaramine-N-oxide
 - The materials may also contain one or more of the following analytes not included in the list of 21 PAs, nor being isomeric analogues, but known to occur in food or feed products:
 - Erucifoline and erucifoline-N-oxide
 - Jacobine and jacobine-N-oxide
 - Jacoline
 - Jaconine
 - Monocrotaline and monocrotaline-N-oxide
 - Trichodesmine

3. Mixed standard solutions

Mixed standard solutions with different combinations of the substances indicated above will be provided. These mixed standard solutions can be used by the participant for optimisation of the analytical method and for quantification of the test materials. They will also be used to evaluate the possibility to discriminate between PAs considered for legislation and PAs not considered for legislation.

4. Questionnaire

A questionnaire will be sent electronically. In this questionnaire the participants will be asked to provide information about the laboratory method used. This information is necessary to conduct a more in depth analysis of the results obtained in this research study.

5. Report

- A report of the research study will be dispatched in December 2019.
- Results of the research study will be presented anonymously.
- The follow-up protocol on Research studies from DG Santé by the EURL will be applied.

6. Additional information

- RIKILT is allowed to use the anonymous results of the research study in presentations, seminars and publications.
- RIKILT will never inform third parties (e.g. accreditation bodies) on specific laboratory results without informing the laboratory first.

7. Costs

- For NRLs the participation is free of charge.
- Official laboratories (OLs) can participate as long as sufficient test material is available, at a first come first serve basis. The participation fee is € 270,- (ex. VAT) as a compensation for the preparation and transportation of the samples.
- If an extra batch of samples or mixed standard solutions is needed after the first shipping, the courier costs will be charged.

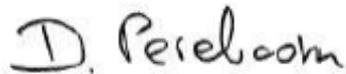

DATE
April 3, 2019

PAGE
3 of 3

Note: The participant should arrange the necessary import permits for the sample materials (if necessary).

If you would like to participate, please fill out the accompanying participation form (preferably digitally) and send it to me before 22 April 2019 to: pt.rikilt@wur.nl.

Hoping to welcome you for this test,

Diana Pereboom-de Fauw

Annex 6 Instruction letter

P.O. Box 230 | 6700 AE WAGENINGEN | The Netherlands

Dear Madam/Sir,

Thank you very much for your interest in the Research Study regarding pyrrolizidine alkaloids in food and feed.

The parcel shipped to you should contain:

- One herbal tea and one alfalfa (lucerne) sample. Each sample contains approximately 25 grams of test material.
- Three mixtures of PA standards. Each vial contains 1.25 mL of the standard mixture dissolved in methanol at a concentration of 5 µg/mL. PA standard mix 1 contains the 21 PAs currently considered for legislation, PA standard mix 2 contains 14 PAs that are isomers of the PAs considered for legislation. PA standard mix 3 contains 9 PAs that are of additional interest for analysis of food and feed samples. The PA standard mixtures can be used to optimise your analytical method and they can also be used for quantification of PAs in the test materials.

- PA standard mixture 1 contains:
 - Echimidine and echimidine-N-oxide
 - Europine and europine-N-oxide
 - Heliotrine and heliotrine-N-oxide
 - Intermedine and intermedine-N-oxide
 - Lasiocarpine and lasiocarpine-N-oxide
 - Lycopsamine and lycopsamine-N-oxide
 - Retrorsine and retrorsine-N-oxide
 - Senecionine and senecionine-N-oxide
 - Seneciphylline and seneciphylline-N-oxide
 - Senecivernine and senecivernine-N-oxide
 - Senkirkine
- PA standard mixture 2 contains:
 - Echinatine and echinatine-N-oxide
 - Heliosupine and heliosupine-N-oxide
 - Indicine and indicine-N-oxide
 - Integerrimine and integerrimine-N-oxide
 - Rinderine and rinderine-N-oxide
 - Spartioidine and spartioidine-N-oxide
 - Usaramine and usaramine-N-oxide

- PA standard mixture 3 contains:
 - Erucifoline and erucifoline-N-oxide
 - Jacobine and jacobine-N-oxide
 - Jacoline
 - Jaconine
 - Monocrotaline and monocrotaline-N-oxide
 - Trichodesmine

Instructions:

- After arrival the samples should be stored at +4°C. The standard solutions should be stored at -20°C.
- Please fill out the accompanying acknowledgement of receipt form and return it upon receipt of the samples, preferably by e-mail (pt.rikilt@wur.nl).
- You are requested to analyse all PAs in standard mix 1 and mix 2 and report the retention times obtained with your analytical method for all individual PAs, even in case one or more PAs are not within the scope of your method. These data will be used to evaluate the chromatographic separation of PAs considered for legislation from their isomeric analogues that are not considered for legislation. Provide detailed information on the analysis of the PA mixes and the analytical method used in the questionnaire and send it by e-mail (pt.rikilt@wur.nl).
- You can download the EURL method for analysis of PAs using LC-MS/MS v1, used for the EURLMP trainings in November 2018, from the EURL mycotoxins & plant toxins website (www.rikilt.nl/eurl) under 'Library'. Please note that the EURL-MP-method-002-v2, for analysis of PAs with specific instructions for the proficiency test, will be placed on the website soon. EURL-MP-method-002-v2 will contain detailed information on the analysis of all PAs included in mixtures 1, 2, and 3.
- Before analysis, homogenize the samples according to your laboratory's procedure.
- Treat the test material as if it was a sample for routine analysis. Report one result and not an average of multiple measurements.
- Report for the test materials all results in µg/kg for the product as received. When a toxin is not within your scope, please report 'nt (not tested)' in the web application. Do not use the option 'detected' from the web application. When a toxin is 'not detected' or the result is below your LOQ, report the result as <LOQ-value and specify the value (e.g. <10 µg/kg).
- Please use the web application for entering your results for the test samples (<https://crlwebshop.wur.nl/apex/f?p=107:LOGIN>). Information about the use of this web application was sent to you earlier by e-mail.
- The deadline for submitting test-results for this test is **June 24th 2019**.

Your username is:

- Your password is:
- Your lab code to enter this proficiency test is:

Please contact me if you have any questions or need any assistance.

With kind regards,

Diana Pereboom

A = assigned value (robust mean).

u = uncertainty of consensus value.

σ_p = target standard deviation for proficiency.

robust σ = robust (relative) standard deviation based on participants' results.

participant 9570 reported 4 components in method. Not included in overall calculations.

nd = not detected; nt = not tested.

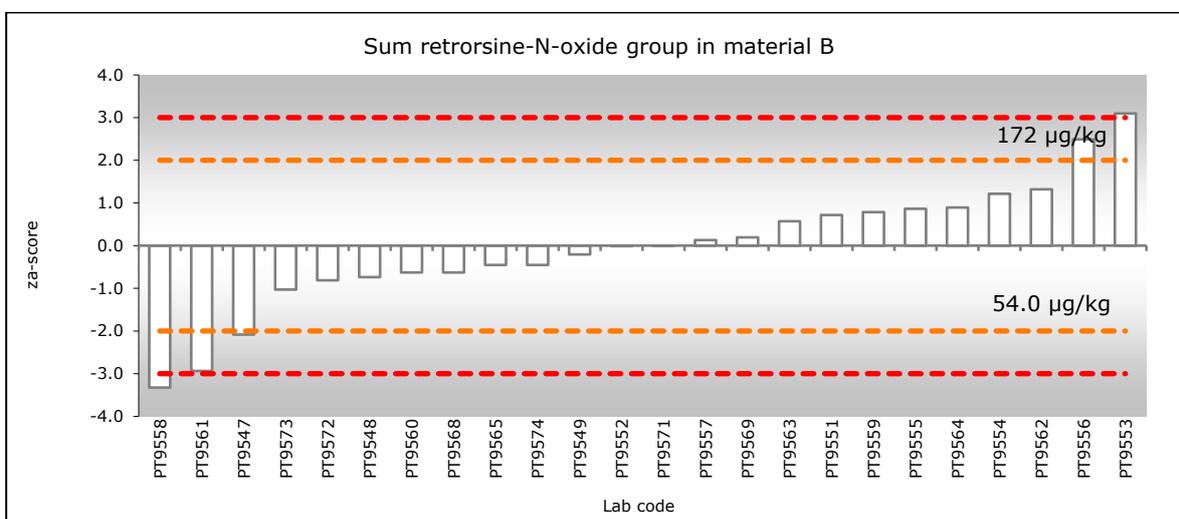

Graphical representation of the z'-scores for retrorsine in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

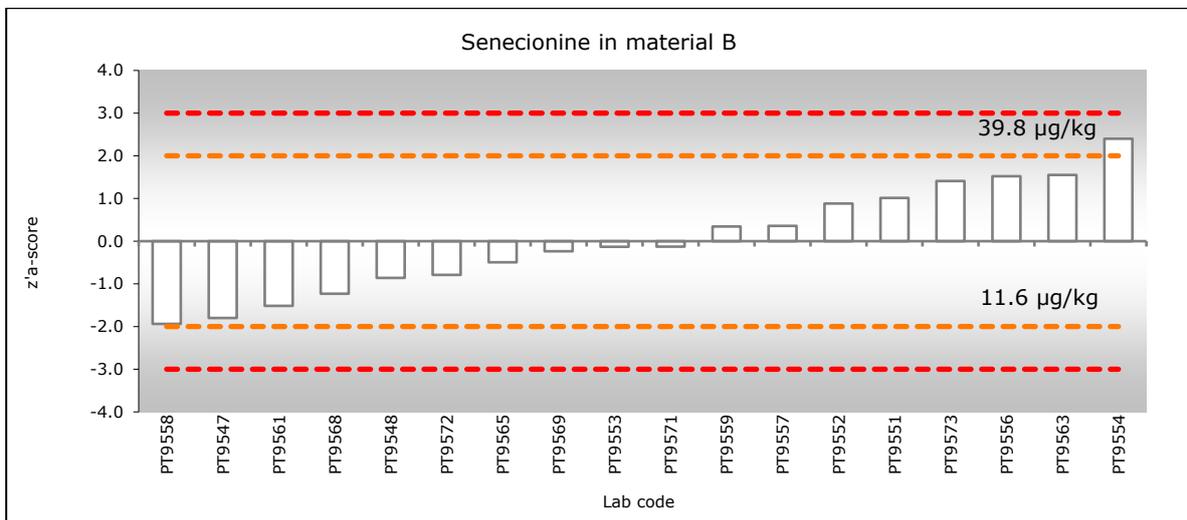

Graphical representation of the z-scores for sum retrorsine group in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

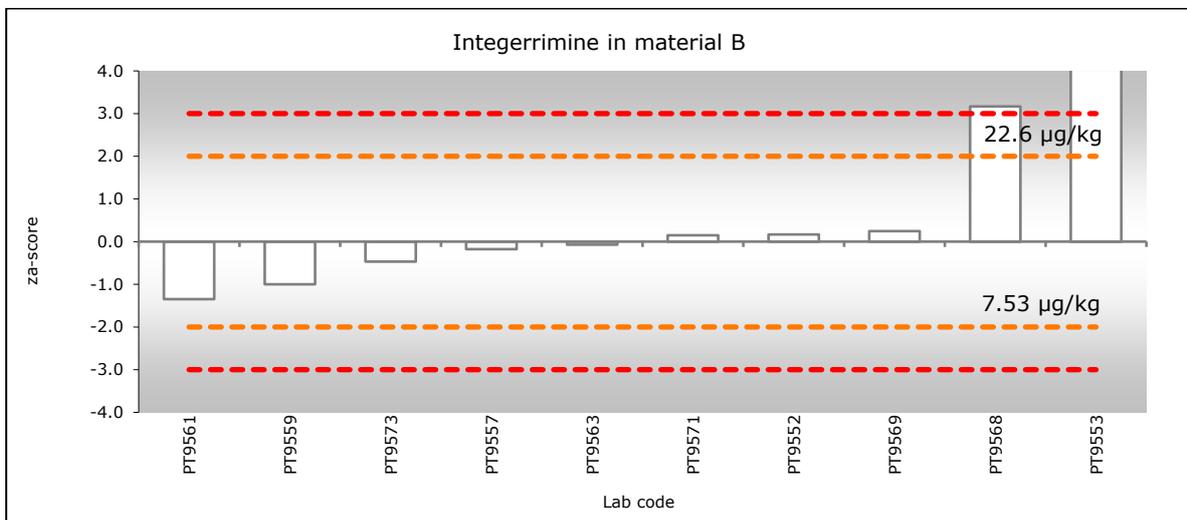

Graphical representation of the z-scores for retrorsine-N-oxide in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

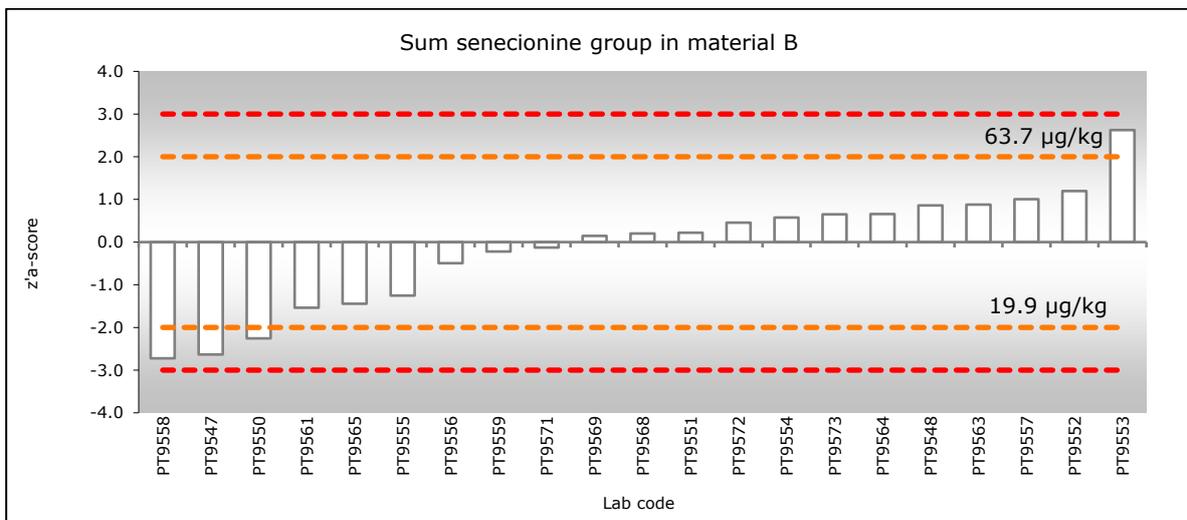

Graphical representation of the z-scores for sum retrorsine-N-oxide group in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

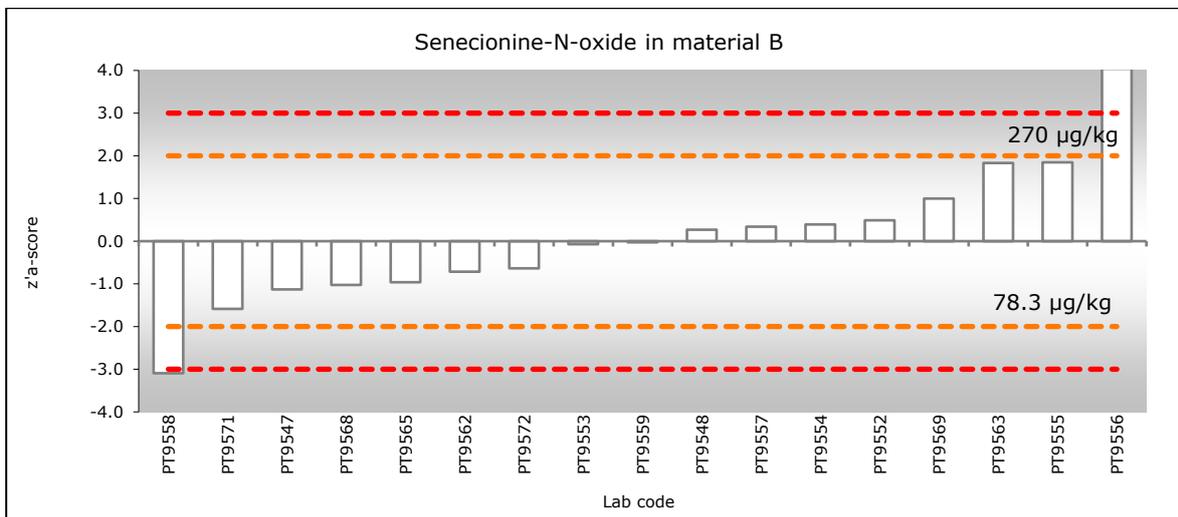

Graphical representation of the z'-scores for senecionine in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

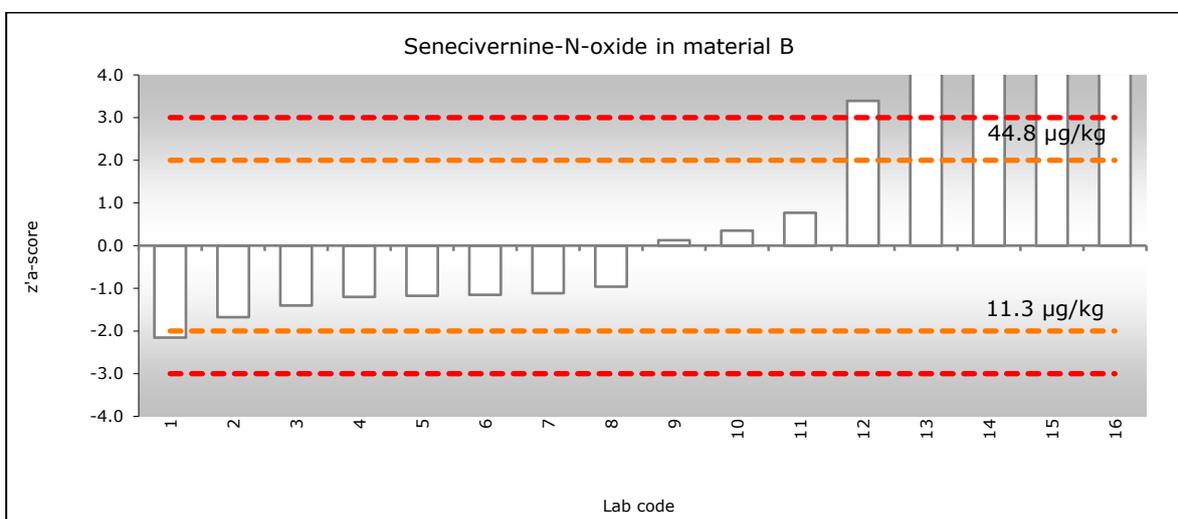

Graphical representation of the z'-scores for integerrimine in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

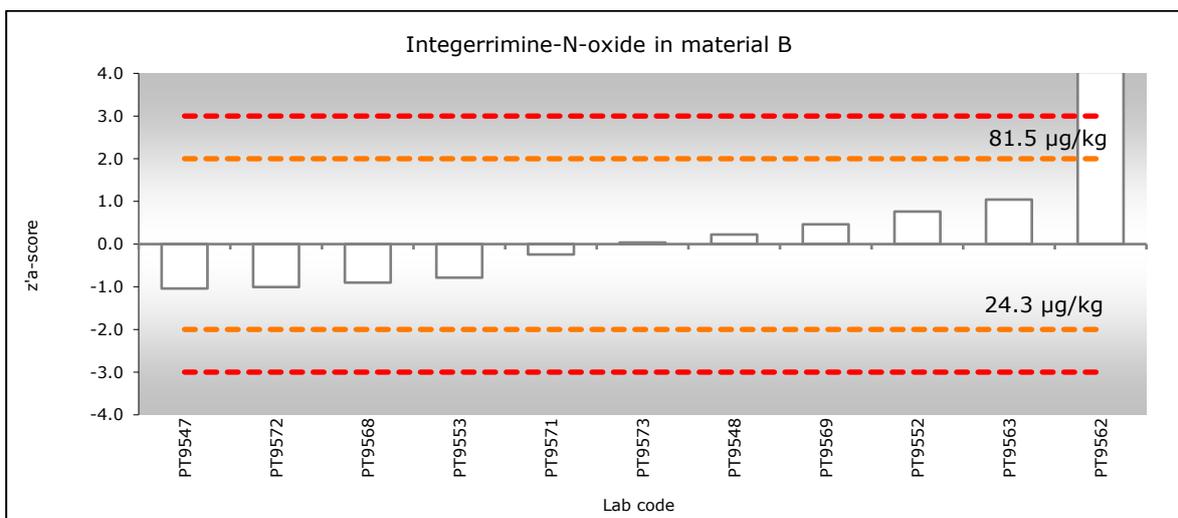

Graphical representation of the z'-scores for sum senecionine group in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

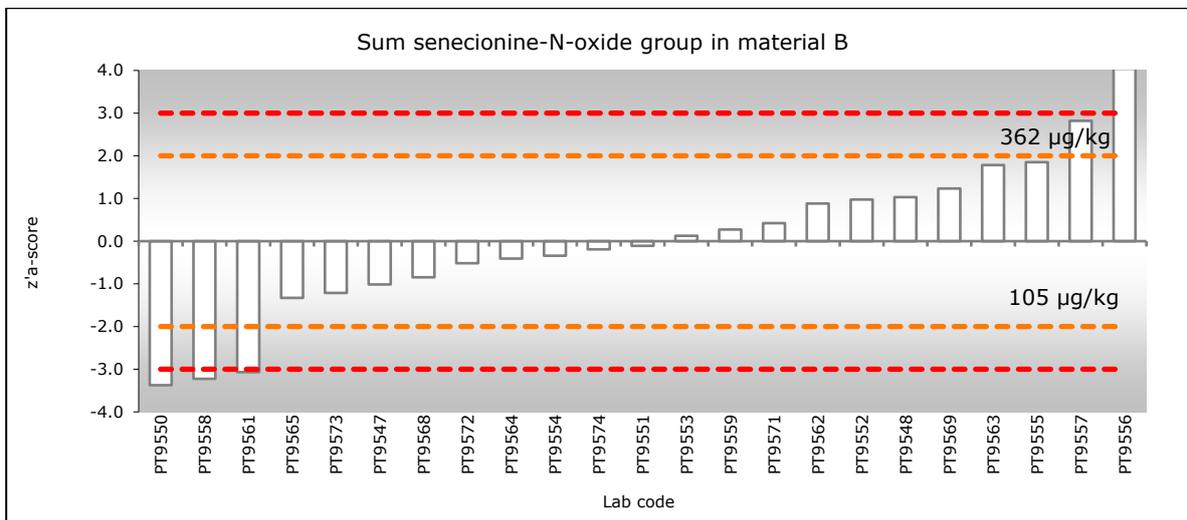

Graphical representation of the z'-scores for senecionine-N-oxide in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

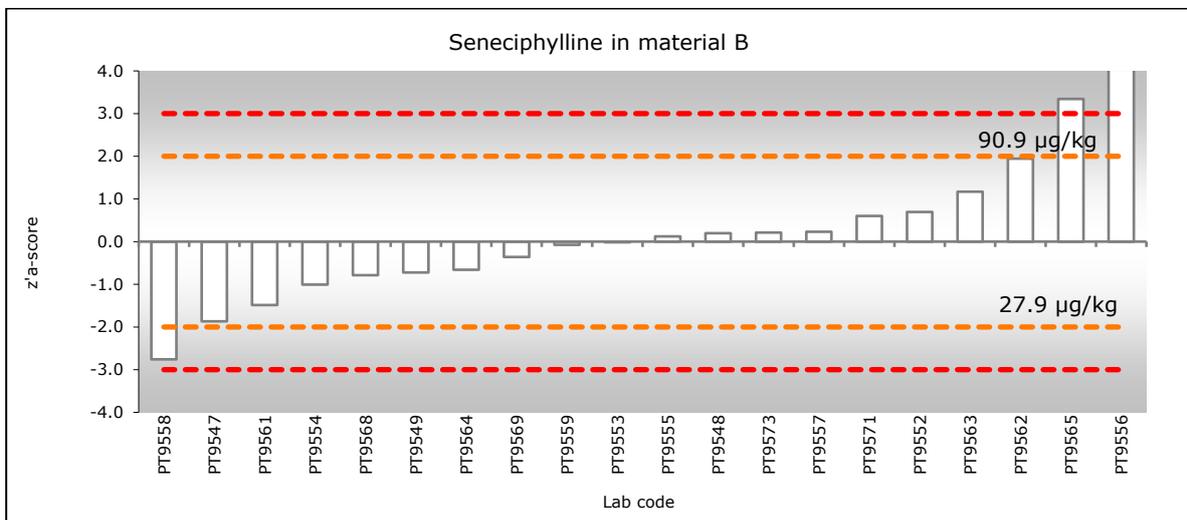

Graphical representation of the z'-scores for senecivernine-N-oxide in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

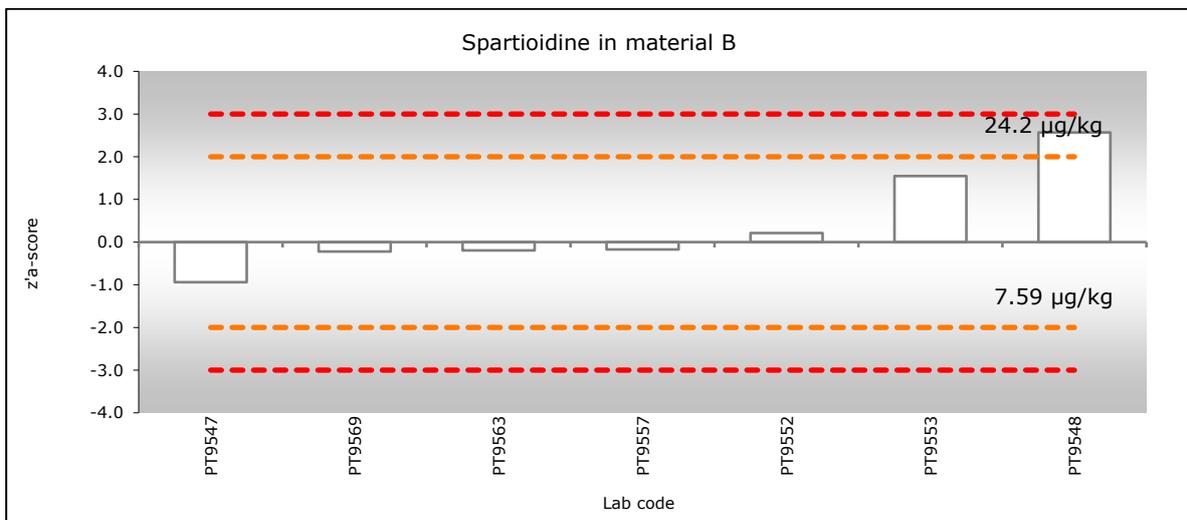

Graphical representation of the z'-scores for integerrimine-N-oxide in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

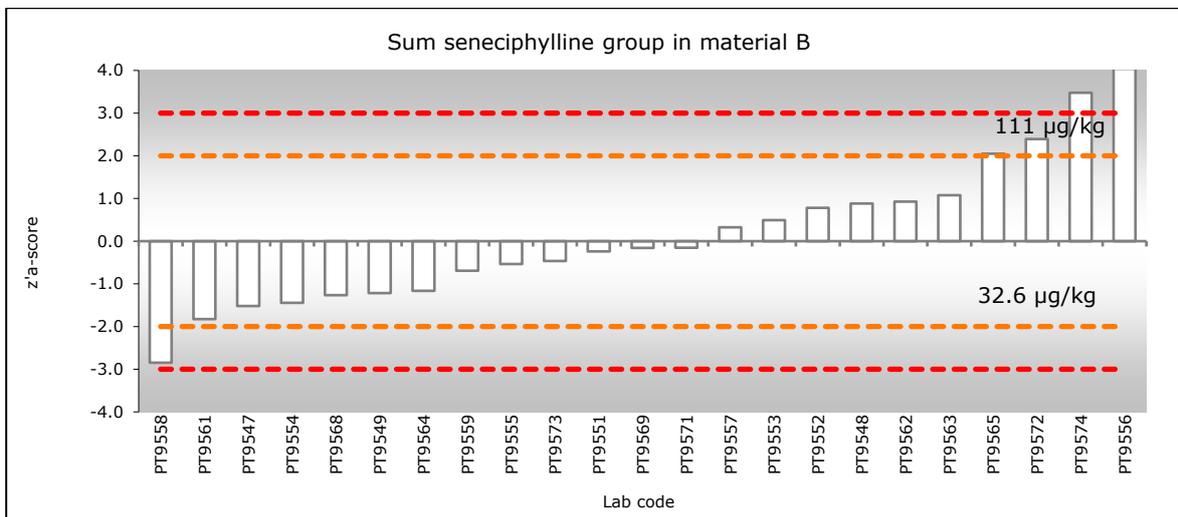

Graphical representation of the z'-scores for sum senecionine-N-oxide group in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

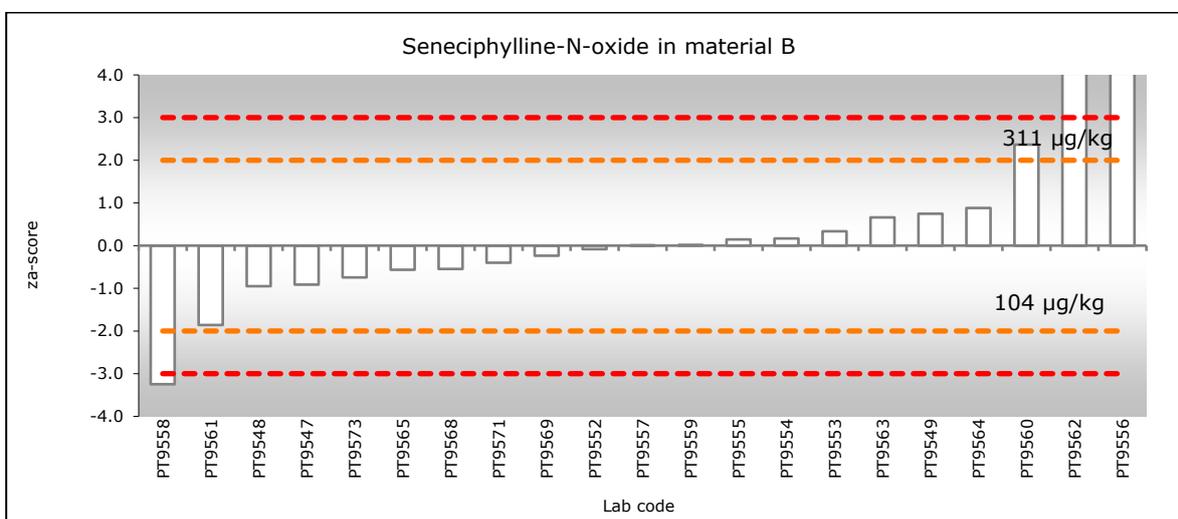

Graphical representation of the z'-scores for seneciphylline in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

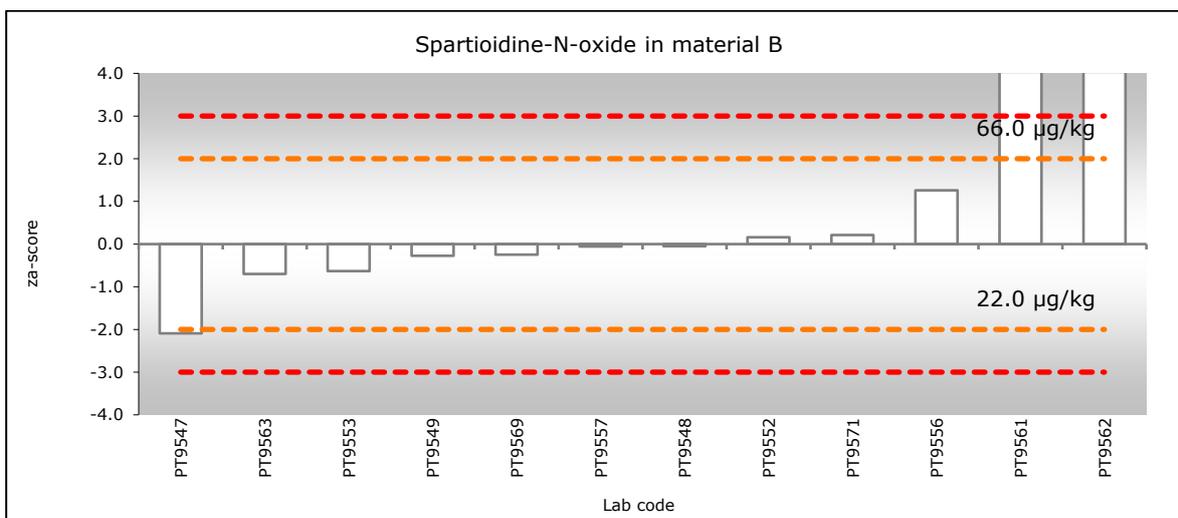

Graphical representation of the z'-scores for spartioidine in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

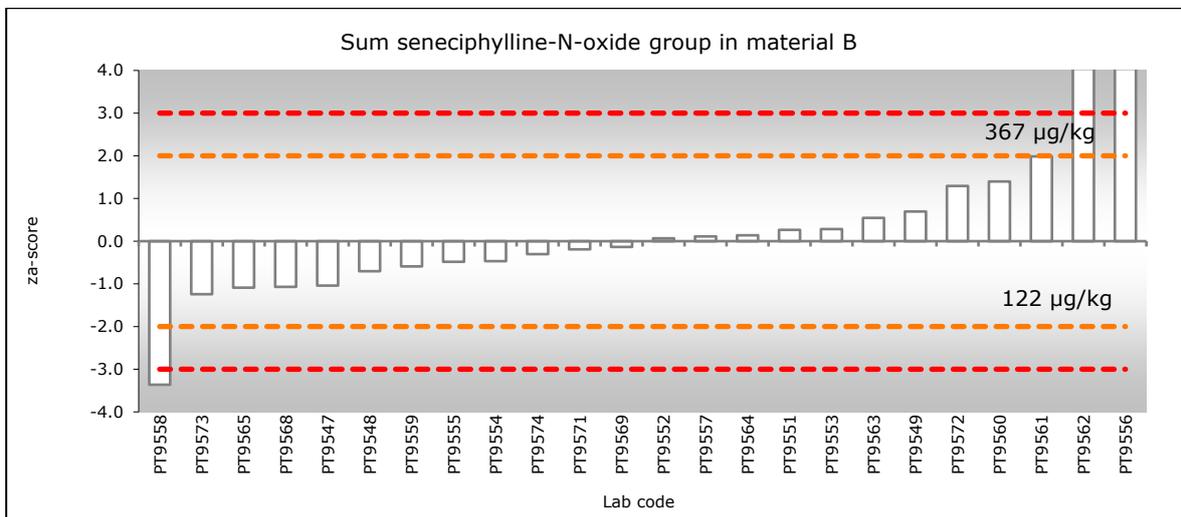

Sum seneciphylline group - Graphical representation of the z'-scores for sum seneciphylline group in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

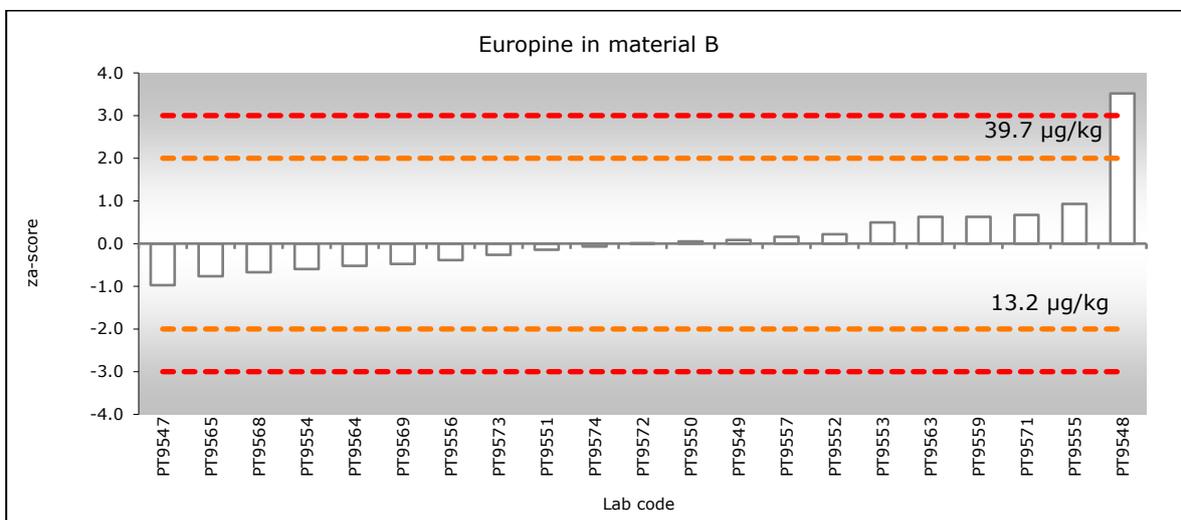

Graphical representation of the z-scores for seneciphylline-N-oxide in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

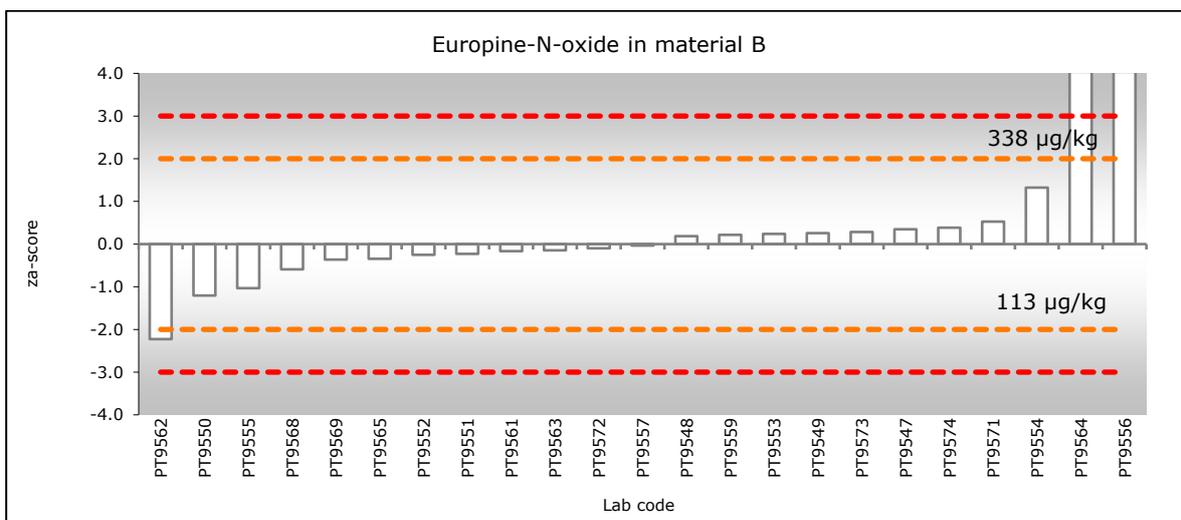

Graphical representation of the z-scores for spartioidine-N-oxide in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

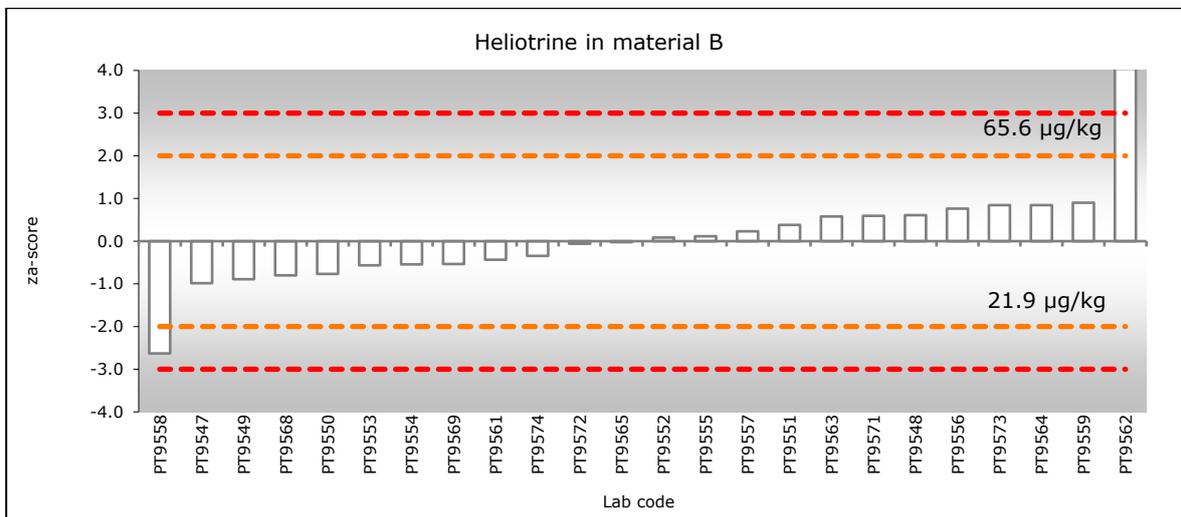

Graphical representation of the z-scores for sum seneciphylline-N-oxide group in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

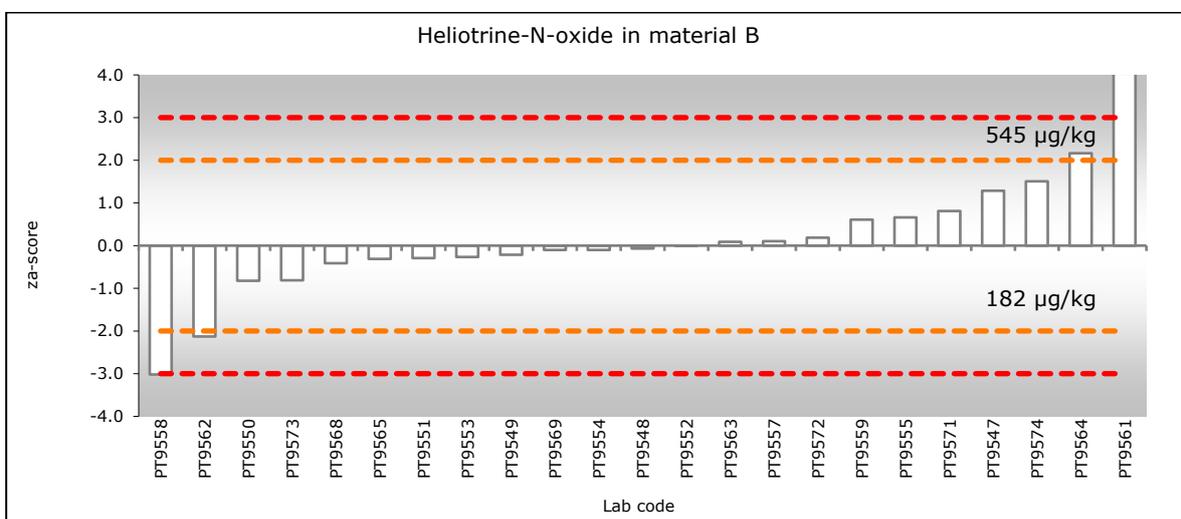

Graphical representation of the z-scores for europine in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

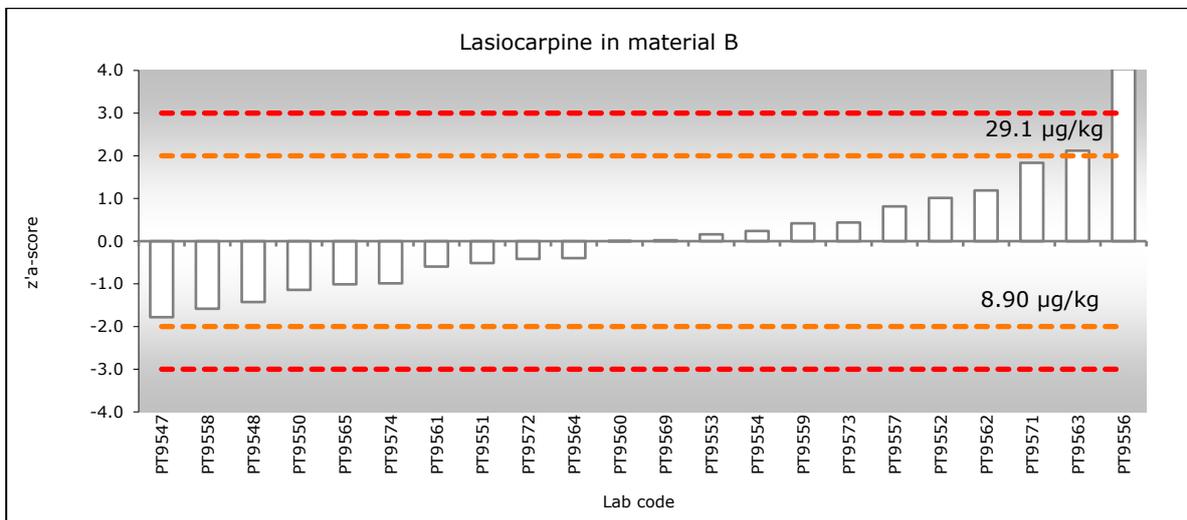

Graphical representation of the z-scores for europine-N-oxide in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

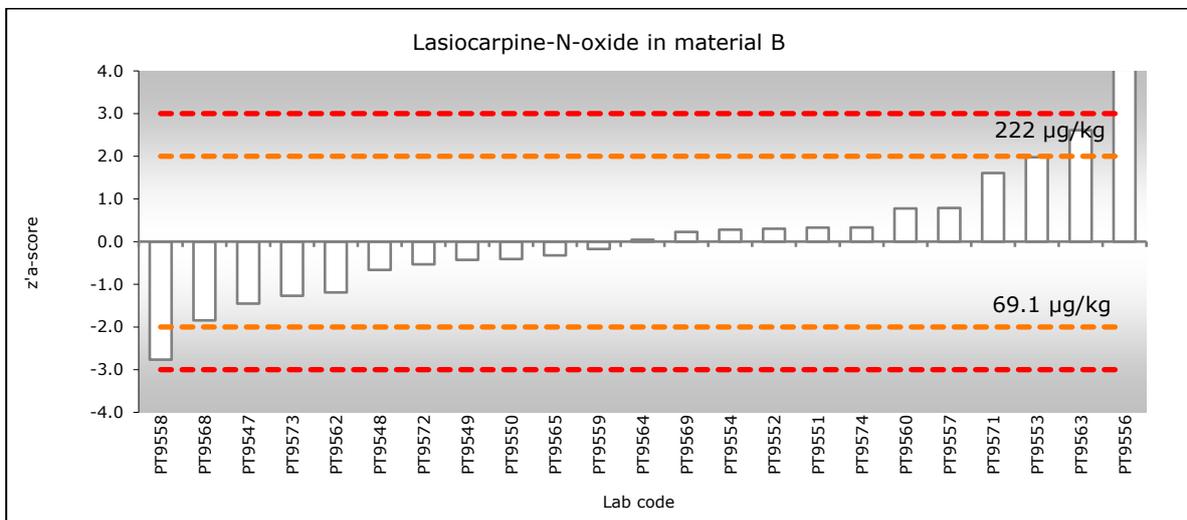

Graphical representation of the z-scores for heliotrine in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

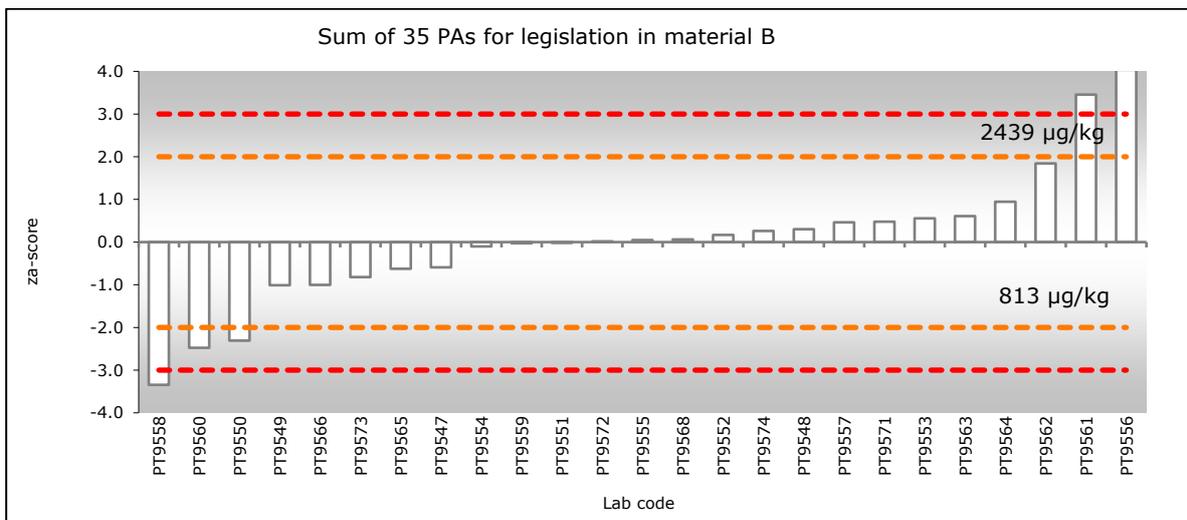

Graphical representation of the z-scores for heliotrine-N-oxide in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

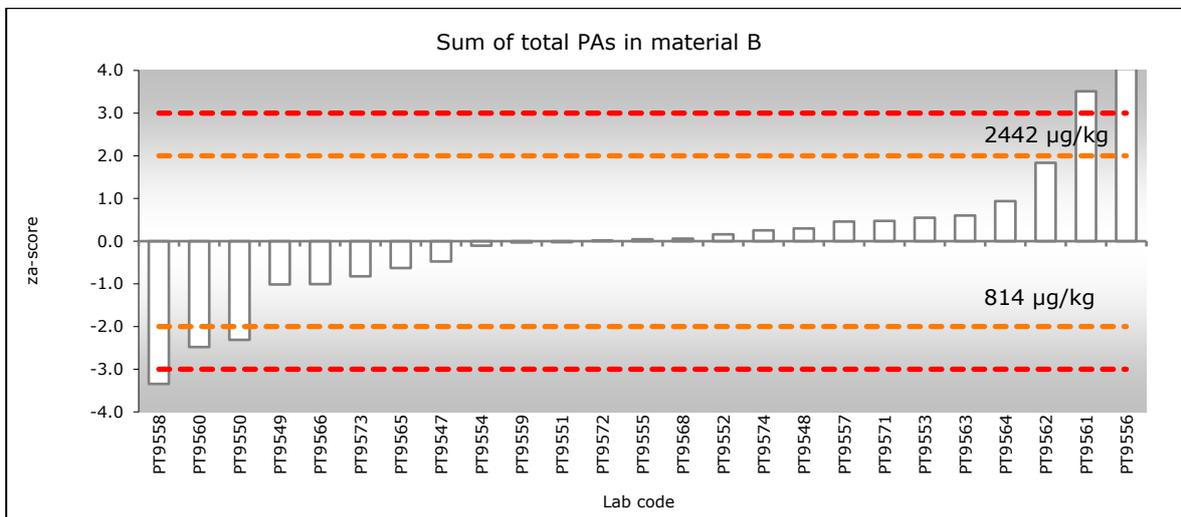

Graphical representation of the z'-scores for lasiocarpine in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

Graphical representation of the z'-scores for lasiocarpine-N-oxide in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

Graphical representation of the z-scores for sum of 35 PAs for legislation in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

Graphical representation of the z-scores for sum of total PAs in material B. Dotted lines show research study performance boundaries ± 2 (also in $\mu\text{g}/\text{kg}$) and ± 3 .

WFSR report 2021.006

The mission of Wageningen University & Research is "To explore the potential of nature to improve the quality of life". Under the banner Wageningen University & Research, Wageningen University and the specialised research institutes of the Wageningen Research Foundation have joined forces in contributing to finding solutions to important questions in the domain of healthy food and living environment. With its roughly 30 branches, 6,500 employees (5,500 fte) and 12,500 students, Wageningen University & Research is one of the leading organisations in its domain. The unique Wageningen approach lies in its integrated approach to issues and the collaboration between different disciplines.
