

BREAKING DOWN THE BARRIERS

THE EFFECTS OF AGING, GUT MICROBIOTA AND BILE ACIDS ON INTESTINAL HEALTH

BENTHE VAN DER LUGT

# BREAKING DOWN THE BARRIERS

THE EFFECTS OF AGING, GUT MICROBIOTA AND BILE ACIDS ON INTESTINAL HEALTH

BENTHE VAN DER LUGT

## PROPOSITIONS

1. A low, rather than a high ratio of sulfated over unsulfated secondary bile acids would be beneficial for IBD patients during a flare.  
(this thesis)
2. To be physiologically representative, intestinal *in vitro* models require shear stress.  
(this thesis)
3. Price-consciousness is a crucial aspect of scientific integrity.
4. The duration of a PhD track is insufficient if a fundamental part of a project requires optimization.
5. A transition from an individualistic towards a collectivist society is needed in our race against climate change.
6. The analogy between cycling and everyday life is striking, given the alternating episodes of headwind and tailwind.

Propositions belonging to the thesis, entitled

Breaking down the barriers: The effects of aging, gut microbiota and bile acids on intestinal health

## CHAPTER 1

# General introduction

## Intestinal health

The actuality of Hippocrates' quote "*All disease begins in the gut*" is still valid, given the high number of studies focusing on the relationship between the intestine and health. Although one should not interpret this quote as explicitly as it sounds, indeed, many disorders are linked to intestinal health. The intestinal tract is a large organ that harbors and interacts with trillions of micro-organisms and forms a barrier to prevent potential harmful compounds entering the bloodstream. To run all these processes smoothly, intestinal cells and their reaction to environmental stimuli should be in ingenious balance. The moment these finely regulated processes are hampered, the risk of (intestinal) diseases increases.

## Functions of the gastrointestinal tract

All consumed foods and drinks pass through the gastrointestinal (GI) tract, following the route from mouth to anus. During this journey, every part of the GI tract has its own specific role in digesting and absorbing the food. Mainly in the lower intestinal tract, i.e. the small and large intestine (colon), nutrients are taken up by intestinal absorptive cells, or enterocytes (1). In the colon, nutrients and water are absorbed and the indigestible parts that are left are ready for excretion via the feces. The structure of the epithelium in the small intestine is characterized by the presence of villi, i.e. small finger-like structures that greatly increase the surface area of the intestine and thereby maximize the absorption of nutrients (2). The epithelium of the colon does not possess villi, but has a rather flat appearance. In the small intestine and colon, crypts of Lieberkühn are located, which are epithelial invaginations where intestinal stem cells (ISCs) reside (3). ISCs are rapidly dividing cells necessary for the constant renewal of the intestinal epithelium. These ISCs give rise to either absorptive or secretory progenitors, which can differentiate into six specialized epithelial cell types (**Fig. 1**). Absorptive progenitors differentiate into enterocytes, or colonocytes, as they are called in the colon. Of all cell types, enterocytes are the most densely populated and are responsible for the absorption of nutrients and water. The less well known microfold (M) cells also originate from absorptive progenitors and play an important role in mucosal immunity by their ability to take up luminal antigens (2). The other four cell types originate from secretory progenitors. Goblet and enteroendocrine cells produce and secrete mucus and hormones, respectively. In contrast to other intestinal cell types, Paneth cells stay at the bottom of the crypt and are responsible for the production of antimicrobial compounds. Also the remaining cell type, the Tuft cell, is involved in the protection against intruders, since it combats parasite infection (2).

Altogether, different types of IECs have their own specialized functions and contribute to intestinal homeostasis. It is important to realize, however, that recent studies have shown that multiple subsets exist within the same cell type. For example, a subtype of goblet cells located at the mouse colonic crypt entrances was discovered (4). These so-called sentinel goblet cells are able to protect the colonic crypts by secreting mucus in the presence of invading bacteria (4). Also, subtypes of enterocytes, enteroendocrine cells and Tuft cells are known (2), highlighting the extensiveness and complexity of IECs.

**Figure 1** A schematic overview of the development of intestinal stem cells (ISCs) into two cell lineages: absorptive cells (enterocytes and M cells) and secretory cells (goblet, Paneth, tuft and enteroendocrine cells).

## Intestinal barrier function

The intestine is continuously exposed to external factors that enter the body mainly via the ingestion of food. Exposure to these external factors might pose a risk when toxic compounds are co-ingested and exert potentially harmful effects. Moreover, the presence of an incredibly high number of bacteria in the intestine requires a well-functioning defense mechanism to avoid the invasion of bacteria. Therefore, an essential function of the intestine is to maintain a finely tuned balance between an efficient uptake of nutrients on the one hand, and the restriction of the entrance of toxic compounds and bacteria on the other hand. This highly complex task is delegated to the intestinal barrier, which consists of multiple layers that work in concert to keep intestinal homeostasis. Following the order from intestinal lumen to the mucosal tissue, these layers include the mucus layer, the intestinal

epithelial cell layer and the immune cell 'layer'. Important similarities and differences between the intestinal barrier function in the small intestine and colon are depicted in Figure 2.

**A**

**B**

**Figure 2** Schematic overview of the different components of the intestinal barrier in the small intestine (SI) and colon. **(A)** In the small intestine, both villi and crypts are present. Antimicrobial peptides (AMPs), Immunoglobulin A (IgA) and intestinal alkaline phosphatase (IAP) protect against bacterial invasion. Tuft cells protect against parasites, such as helminths. The mucus layer in the SI is rather discontinuous, while in the mucus layer in the colon is thick **(B)** and consists of two layers: a firm inner layer that is devoid of bacteria, and a loose outer mucus layer is inhabited by bacteria. High amounts of IgA, AMPs and IAP are present in the mucus layers that protect against invasion of bacteria.

## Mucus layer

The mucus layer covering the epithelial cells has a dual role: on the one hand, it acts as a protective physical barrier, and on the other hand, it serves as a nutrition source for commensal bacteria (5). These functions are accounted for by the complex structure of mucus. The mucus secreted along the intestinal tract is mainly composed of the gel-forming mucin type 2 (MUC2). MUC2 is part of a large family of mucins that consist of both secreted and transmembrane mucins. Next to MUC2, other gel-forming mucins include MUC5AC, MUC5B and MUC6. However, these mucins are mainly expressed in the stomach and are not, or very weakly, expressed in the intestine (6). In addition to secreted mucins, enterocytes produce another type of mucins: the transmembrane mucins. These membrane-bound mucins are large glycoproteins that are characterized by a long and highly glycosylated extracellular domain that is part of the intestinal barrier (7). The mucin core domain consists of repetitive tandems of proline, threonine and serine (PTS), which are heavily O-glycosylated at the hydroxyl group of serine or threonine (8) (**Fig. 3**). The N- and C-termini of gel-forming mucins are kept together by disulfide bonds between cysteine amino acids. Transmembrane mucins are attached to the cell membrane by either sea urchin-enterokinase-agrin (SEA) domains or von Willebrand domains (vWD). The intracellular domain (cytoplasmic tail) has the potential to be phosphorylated, thereby exerting signaling functions, such as immune modulation and regulation of cell proliferation and apoptosis via different signaling pathways (9, 10).

The high amount of glycans makes MUC2 water soluble, reflected by the high water content of mucus (90-95%). Together with electrolytes, lipids, immunoglobulins and many other proteins, MUC2 forms an expanded net-like structure (11, 12). The protective role of the mucus layer is based on the physical barrier that avoids direct contact between bacteria in the lumen and the IEC layer. Importantly, the organization of the mucus layer along the intestinal tract is different. In the small intestine, the mucus layer is loose and not attached to the underlying epithelial cells (13) (**Fig. 2A**). In the colon, a double mucus layer exists: an impenetrable inner layer which is firmly attached to the intestinal epithelial cells and is devoid of bacteria, and a loose and penetrable outer layer

which is colonized by commensal bacteria (14, 15) (**Fig. 2B**). Apparently, the thickness of the mucus layer is highly dependent on the number of bacteria present, as the mucus layer is thicker in the bacteria-dense colon compared to the small intestine, where far fewer bacteria are present (16). The indispensability of bacteria for a properly functioning mucus layer was emphasized in studies which showed that the mucus layer of germfree rats was very thin. In addition, mucus composition, compactness and mucin content was negatively affected (17). Moreover, the composition of the gut microbiota was shown to be an important indicator of a well-functioning mucus layer (18).

**Figure 3** A schematic, simplified overview of the structure of gel-forming and transmembrane mucins. The mucin core domain consists of repetitive tandems of proline (Pro), serine (Ser) and Threonine (Thr). The latter two amino acids are attachment sites for O-glycosylation with N-acetylgalactosamine (GalNAc). Transmembrane mucins are bound to the cell membrane by sea urchin-enterokinase-agrin (SEA) domains or von Willebrand domains (vWD). The cytoplasmic tail (CT) is located inside the cytoplasm.

Next to its role as physical barrier to protect bacteria coming in contact with IECs, mucus has another beneficial function as food source for commensal bacteria (5). The so-called mucin-degrading bacteria produce enzymes that allow them to metabolize mucin glycans (**Fig. 2B**) (6). A well-known mucin-degrading bacteria is *Akkermansia muciniphila*, which belongs to the phylum of Verrucomicrobia (19). Besides, many members of the phyla Bacteroidetes (*Bacteroides*

*thetaiotaomicron* and *Bacteroides fragilis*) and Firmicutes (*Ruminococcus torques* and *Ruminococcus gnavus*) have been described as mucin-degrading bacteria, but also from the phyla Actinobacteria (*Bifidobacterium bifidum*) amongst others (6, 20). Mucin-degrading bacteria have several important roles in intestinal homeostasis. Under the influence of mucin-degrading bacteria, the mucus layer is continuously degraded, which stimulates the production of mucus again. This process, which is known as mucus turnover, is essential for a healthy mucus layer (19). As both the host and bacteria benefit, this microbe-mucus interaction can be seen as a mutualistic relationship. First, the degradation of mucins leads to the production of SCFAs that provides extra energy needed for the energy-demanding process of the synthesis and secretion of MUC2 (21). Second, mucin-degrading bacteria can directly inhibit the colonization of pathogens, e.g. by 1) producing antimicrobials, 2) depleting the available nutrients or 3) reducing oxygen levels (as most pathogens use oxygen for growth) (22). Third, the close proximity of mucin-degrading bacteria to the intestinal epithelial layer leads to a finely regulated immune response that provides protection against pathogens (22). Altogether, these examples emphasize the important role of mucus-gut microbiota interactions by maintaining a finely tuned balance between MUC2 production by the host and mucin-degradation by the gut microbiota (21).

### Intestinal epithelial cells

The monolayer of IECs that is underlying the mucus layer is also a physical barrier. A crucial role of this cellular monolayer is to allow the transport of nutrients, water and ions, yet prevent the entrance of potential harmful components (23). To maintain this selective permeable barrier, IECs are strongly connected to each other by specialized proteins called tight junctions (TJs) (23, 24). TJs are multi-protein complexes and can be classified into families of transmembrane and cytosolic proteins. Each of these families consist of different members. The four families of transmembrane proteins include occludin, claudin, junctional adhesion molecule (JAM), and tricellulin (23). While the first three TJ proteins seal two adjacent cells, tricellulin connects the junctions of three cells (24). The TJ proteins interconnect with cytosolic proteins, such as the family of zonula occludens (ZO1, 2, 3) and cingulin. In turn, the ZOs and cingulin act as adaptors that form strong connections between transmembrane proteins and the perijunctional actomyosin ring, thereby anchoring the protein complex to the cytoskeleton (24, 25) (**Fig. 4**). The ingenious complex of TJ proteins and their interaction with the actomyosin ring is under strict regulation. Constant signaling between the individual components results in the opening and closure of the paracellular space upon a wide range of external stimuli

and physiological and pathological conditions (24, 26). Phosphorylation of TJs plays an important role in regulation of intestinal epithelial barrier function. Key signaling proteins involved in this process include protein kinase C (PKC), mitogen-activated protein kinases (MAPK), myosin light chain kinase (MLCK), and the Rho family of small GTPases, which control the (dis)assembly and maintenance of TJs (24).

**Figure 4** Schematic overview of the tight junction (TJ) proteins, adherens junctions (AJs) and desmosomes present in the intestinal cell that seal adjacent cells.

Next to the physical defense, another defense mechanism attributed to IECs is the production of intestinal alkaline phosphatase (IAP) (**Fig. 2A-B**). IAP is a brush border enzyme secreted at both the apical and basolateral side of the IEC. It has multiple important functions to keep intestinal homeostasis (27). In relation to the intestinal barrier, the most important function of IAP is the ability to dephosphorylate LPS. This removal of phosphate groups leads to a significant reduction in the toxicity of LPS by inhibiting downstream pro-inflammatory reactions (27).

## Immune cell layer

The third layer of defense is not an actual physical layer, but includes specialized cells of the immune system that participate in the tolerance and protection against external substances (**Fig. 2A-B**). The intestine is an organ with a high number of immune cells, emphasizing the important role of the intestinal immune system. The gut-associated lymphoid tissue (GALT) consists of lymphoid structures that are all dedicated to sample foreign antigens and induce an adaptive immune response (28). Peyer's patches (PPs) are the main lymphoid tissue located in the small intestine (**Fig. 2A**). Specialized cells in the PP include Microfold (M) cells, which are responsible for the uptake and transport of antigens to mononuclear phagocytes, such as macrophages and dendritic cells (DCs). These antigen-presenting cells present the antigens to a variety of adaptive immune cells that act in concert to detoxify the foreign substances. In the protection against pathogens and tolerance to commensal bacteria, Immunoglobulin A (IgA) plays an important role. Specific subsets of intestinal DCs induce the production of IgA by B cells (29). IgA is able to interfere with gut bacteria and neutralize toxins, thereby preventing these harmful compounds from coming in contact with the IEC layer (30). In the colon, where no PPs are present, caecal patches are the equivalent of PPs. From these structures, IgA secreted by plasma cells migrates to the colon to exert its immune-related functions (31).

Although strictly not a barrier, another important antimicrobial defense mechanism is organized by Paneth cells. These cells are located in the base of the crypts in the small intestine (32). Upon bacterial stimulation via Toll like receptors (TLRs), Paneth cells produce a range of antimicrobial peptides (AMPs), such as defensins, regenerating islet-derived protein IIIA (REGIII A) and lysozyme, amongst others (3, 33). The antimicrobial properties of AMPs are executed either by directly killing the bacteria by permeabilizing the membrane, or intracellularly by inhibiting essential cell processes (34). Although Paneth cells are absent in the human colon, a high amount of functional AMPs was found to be present in rectal mucus extracts, indicating that AMPs are retained in the mucus without losing their function (35). Furthermore, other sources of intestinal AMPs are also known: enterocytes, infiltrating neutrophils and the bacteria present in the intestine are three other sources of AMPs (36).

Paradoxically, to have a fully functional intestinal barrier, the host is highly dependent on bacteria present in the intestinal lumen and mucosa. The presence of bacteria results in the development and maintenance of the intestinal barrier (37). Importantly, germfree mice have an underdeveloped GALT, and also immune tissues outside the intestine (e.g. spleen and lymph nodes) are poorly developed (38)s. These immune deficits render germfree animals more prone to infections (39).

## **Gut microbiota**

The intestine is densely populated with a variety of microorganisms, also known as the gut microbiota. This diverse community is dominated by the presence of bacteria, but also includes fungi, viruses, archaea and protozoa (40). To date, numerous bacterial phyla have been discovered. The phyla that are mainly present in the intestine are Bacteroidetes and Firmicutes, and to a lesser extent Proteobacteria, Actinobacteria, Fusobacteria, Verrucomicrobia and Cyanobacteria (41). The number of bacteria as well as the bacterial diversity increases along the GI tract, with the highest density and diversity found in the colon (38). The human gut microbiota is of utmost importance for host health, not only with regard to intestinal health, but also beyond (42). A healthy intestine is characterized by a highly diverse microbiota composition, with the presence of beneficial commensal bacteria and the absence of infection and bacterial overgrowth (43). Many of the health effects attributed to the gut microbiota are mediated by bacterial metabolites, which are intermediates or end products of bacterial metabolism (44). In the colon, the most intensively studied bacterial metabolites are short-chain fatty acids (SCFAs) and bile acids (BAs).

## **Short-chain fatty acids**

Diet is an important source of precursors for the production of bacterial metabolites. By far the most intensively studied diet-derived bacterial metabolites are the SCFAs butyrate, propionate, and acetate. These compounds are produced upon bacterial fermentation of indigestible carbohydrates and exert a variety of beneficial effects for the host. Amongst others, SCFAs can be used as energy source. Butyrate is mainly used as fuel for colonocytes (45), while acetate and propionate can be used in the liver as precursors for gluconeogenesis and lipogenesis, respectively (46). Furthermore, SCFAs are known to strengthen the intestinal barrier by upregulating the expression of TJ genes, increasing AMP production, and decreasing inflammation (47). SCFAs also play a role in the regulation of satiety and intestinal transit via activation of G-protein coupled receptors (GPCRs), thereby releasing PYY and GLP-1 (48). These indirect effects of SCFAs imply that their beneficial health effects extend beyond the intestinal tract.

## **Bile acids**

Bile acids (BAs) include another group of metabolites with effects on intestinal health as well as overall health. The primary BAs cholic acid (CA) and chenodeoxycholic acid (CDCA) are produced in the liver by the conversion of cholesterol through a series of complex enzymatic pathways, with

CYP7A1 as the rate-limiting enzyme (49). After synthesis, primary BAs are conjugated with taurine or glycine and transported via the bile salt export pump (BSEP, ABCB11). Conjugation of BAs prevents passive absorption and promotes solubility in the proximal intestine (50). These changes in their physicochemical properties are important for the maintenance of high luminal concentrations of conjugated BAs and thereby for the digestion and absorption of dietary fats (50-52). Of all produced BAs, 95% is reabsorbed in the small intestine by the apical bile salt transporter (ABST, SLC10A2). In the enterocyte, BAs are bound to the ileal bile acid binding protein (IBABP, FABP6), are excreted via the basolateral organic solute transporters alpha and beta (OST $\alpha$ / $\beta$ , SLC51A/B) and travel via the portal vein back to the liver, where reuptake takes place via the Na<sup>+</sup>-taurocholate polypeptide (NTCP, SLC10A1). This elegant process of BA recirculation is called the enterohepatic cycle and is highly important for metabolic homeostasis (49) (**Fig. 5**). The small fraction (5%) of BAs that escapes the enterohepatic cycle enters the colon, where the gut microbiota transform the primary BAs into secondary BAs. First, conjugated BAs are deconjugated by the bacterial enzyme bile salt hydrolase (BSH). The second pathway is the dehydroxylation at position 7 by bacterial dehydroxylases, transforming CA and CDCA in deoxycholic acid (DCA) and lithocholic acid (LCA), respectively (53). Secondary BAs can either be excreted in the feces or are absorbed by IECs and return back to the liver where they enter the enterohepatic cycle again (54) (**Fig. 5**).

**Figure 5** A schematic overview of the enterohepatic cycle. Primary bile acids (BAs) are produced in the hepatocyte. After conjugation, BAs are released in the intestine, where they aid in the emulsification of fat. BAs are then absorbed by the enterocyte and enter the liver again via the portal vein. Unabsorbed BAs are transformed by bacteria into secondary BAs, which enter the enterohepatic cycle again, or are excreted via feces. In both hepatocytes and enterocytes, FXR has an important role in the regulation of BA production.

---

### BAs as signalling molecules

BAs have a pleiotropic role in the human body. Next to their function as detergents in fat digestion and absorption, BAs also act as signalling molecules by activating the BA receptors FXR (NR1H4) and TGR5 (GPBAR1), resulting in the regulation of a wide range of biological processes (54). The nuclear receptor FXR, which is abundantly expressed in both the liver and intestine, is directly activated by BAs. The most potent FXR activator is CDCA, followed by LCA, DCA, and CA (49). FXR plays an important role in the enterohepatic cycle by regulating the expression of genes related to BA synthesis, secretion, and absorption (49) (Fig. 5). In the enterocyte, FXR activation triggers the production of fibroblast growth factor 19 (FGF19), which inhibits BA synthesis by inhibition of CYP7A1 via fibroblast growth factor receptor 4 (FGFR4). In the hepatocyte, CYP7A1 is also repressed by FXR-mediated regulation of small heterodimer partner (SHP) (55) (Fig. 5). In addition to its role in the regulation of the enterohepatic cycle, FXR is also involved in mucosal protection, cell proliferation, and inflammation (56, 57). It was shown that FXR activation ameliorated intestinal inflammation, inhibited intestinal permeability, and protected against loss of goblet cells in mice suffering from chemically-induced colitis (58). Furthermore, FXR was also shown to be anti-tumorigenic, since FXR-deficient mice had increased colon cell proliferation rates and subsequent tumorigenesis (59).

TGR5 is a G-protein coupled receptor (GPCR) that is ubiquitously expressed throughout the GI tract, but is also expressed in innate immune cells and enteric nerves (60, 61). This cell surface BA receptor is most potently activated by the secondary BAs LCA and DCA, followed by CDCA and CA. However, also conjugated BAs have a high affinity for TGR5 (62). TGR5 plays an important role in several cell signalling pathways with effects on energy homeostasis, insulin secretion, cell proliferation, intestinal motility and inflammation, amongst others (63, 64). Although the exact mechanisms are to be unravelled, it is thought that these effects are mediated by various cyclic AMP signalling pathways (65). In addition to FXR and TGR5, BAs are also ligands for the vitamin D receptor (VDR), pregnane X receptor (PXR) and glucocorticoid receptor (GR), that all have important roles in physiological processes (66).

## Cytotoxic effects of bile acids

Next to their important physiological functions, BAs can also be cytotoxic, which might even have pathological consequences. The detergent properties of BAs could disturb cell membranes by solubilizing membrane lipids (67). Furthermore, high levels of hydrophobic BAs have been associated with colon cancer caused by oxidative stress and DNA damage (68). As a strategy to reduce the cytotoxicity of BAs, the liver conjugates BAs with a sulfonate ( $\text{SO}_3^-$ ) group by the sulfotransferase SULT2A1 (**Fig. 6**) (69). In addition to hepatic BA sulfation, it is known that enterocytes also express SULT2A1, suggesting that BAs are also sulfated in the intestinal tract. Sulfation of BAs results in a hydrophilic molecule that is poorly reabsorbed by the body, and is therefore rapidly excreted via the feces and urine (69). Furthermore, sulfated BAs have less detergent capacities, which could result in less membrane-disturbing effects than their unsulfated counterparts (70). Similar to other BAs, sulfated BAs are subject to bacterial transformation. Indeed, bacterial species that have desulfating capacities include *Clostridium*, *Pseudomonas*, *Peptococcus* and *Fusobacterium* (71).

**Figure 6** Schematic overview of the enzymatic formation of sulfated BAs in the human liver. During this reaction, a sulfonate group ( $\text{SO}_3^-$ ) derived from the universal sulfonate donor 3'-phosphoadenosine 5'-phosphosulfate (PAPS) is transferred to a hydroxyl group. The 3-OH position of BAs is the main target for sulfation in humans. The enzyme catalysing this reaction is sulfotransferase 2A1 (SULT2A1) (69).

## Impaired intestinal barrier function

Following the reasoning that intestinal barrier function plays a crucial role in health, it is not surprising that impaired barrier function is associated with pathogenesis of a wide range of (inflammatory) diseases. Diet and lifestyle, e.g. nutrients, alcohol, smoking, stress and medication use could all have an impact on intestinal barrier function (72). The intestinal barrier can be directly disrupted through the damage of epithelial cells or by disrupted formation and distribution of TJ proteins (73). As a major consequence, breakdown or dysregulation of the intestinal barrier leads to increased translocation of bacterial products (e.g. LPS) and dietary antigens to enter the lamina propria (74) (**Fig. 7**). These stimuli trigger immune cells in the lamina propria, i.e. dendritic cells and macrophages,

to produce pro-inflammatory cytokines. A vicious pro-inflammatory cycle might be induced, as the innate immune cells direct the activation of T cells, which on their turn produce signals that increase further translocation of dietary antigens and bacterial products (75). In addition to local inflammation, an increase in systemic inflammation could also occur when LPS and locally produced pro-inflammatory cytokines enter the bloodstream (75). Examples of diseases caused by local chronic and uncontrolled immune activation as a result of impaired barrier function include inflammatory bowel disease (IBD), coeliac disease and colorectal cancer (73). Importantly, the consequences of impaired barrier function reach far beyond the gut, as evidenced by the contribution to metabolic diseases (obesity and diabetes) (76) as well as neurodegenerative diseases (Parkinson's disease, Alzheimer disease, multiple sclerosis and amyotrophic lateral sclerosis) (77).

**Figure 7** A healthy intestinal barrier is characterized by tightly sealed intestinal epithelial cells. When the intestinal barrier is damaged, disruption of TJs cause opening between the cells, allowing foreign compounds (e.g. bacteria, antigens, LPS) crossing the membrane and activate immune cells in the lamina propria. Immune cell activation leads to increased cytokine production, leading to a pro-inflammatory environment and infiltration of adaptive immune cells. When the immune response becomes uncontrolled, local inflammation extends toward the systemic circulation, which leads to systemic inflammation.

## Inflammatory bowel disease

Inflammatory bowel disease (IBD) comprises the chronic and relapsing inflammatory disorders Crohn's disease and ulcerative colitis, that mainly affect the gastrointestinal tract. Symptoms of this

disease include severe abdominal pain, diarrhea and weight loss, leading to a significant impairment of the quality of life (78). The etiology of IBD remains largely unknown, although it is clear that it is a multifactorial disorder in which genetic susceptibility, environmental stimuli, gut microbiota and exaggerated immune responses play a role (79). It is generally accepted that intestinal homeostasis is disrupted, which is characterized by an imbalance between intestinal barrier components, immune response, and the gut microbiota (80). In IBD patients, a disrupted intestinal barrier is commonly observed, revealed by increased intestinal permeability, reduced mucus layer thickness and Paneth cell dysfunction leading to decreased AMP production (81). These events contribute to the entry of bacterial products, thereby triggering the immune system and causing inflammatory responses (82). The disease course of IBD is typically characterized by alternating periods of active disease (flare) and remission. A disease flare often occurs random and the exact trigger is unpredictable (83).

### **Bacterial metabolites in relation to IBD**

Growing evidence indicates that the gut microbiota is involved in IBD pathogenesis. Intestinal dysbiosis, i.e. an imbalance in gut microbiota composition and function, is associated with IBD (84, 85). Many studies on IBD report a reduced bacterial diversity, a decreased abundance of health-promoting bacteria, together with an increase in potential pathogenic bacteria (86-89). Given the important function of the gut microbiota to produce bacterial metabolites, an alteration in metabolite profile is concomitant with IBD-related dysbiosis. Importantly, a shift in specific types of metabolites could contribute to the pathogenesis of IBD (44). For example, IBD is associated with a loss of butyrate-producing bacteria (90). Consistently, metabolomic studies point toward a decreased abundance of the SCFA butyrate in IBD patients (91-93).

### **Bile acids and IBD**

Another group of bacterial metabolites known to be involved in IBD pathogenesis are BAs. As BAs are enzymatically modified by specialized bacterial species, IBD-related dysbiosis could result in BA dysmetabolism via decreased bacterial enzymatic activity (**Fig. 8**) (88). Indeed, a different fecal BA composition was observed in IBD patients compared to healthy controls, characterized by an increase in primary, conjugated and sulfated BAs, and a decrease in secondary BAs (88, 94-97). Mainly the decrease in secondary BAs could be of importance in relation to IBD progression, given their role as activators of the BA receptors FXR and TGR5. Reduced levels of DCA and LCA may lead to a decreased activation of FXR and TGR5, thereby decreasing their anti-inflammatory effects

(56, 97). Furthermore, secondary BAs are known for their antimicrobial properties by interfering with bacterial membrane lipids (98). FXR activation was shown to promote the production of AMPs in mice (58). An IBD-related decrease in luminal secondary BAs could therefore lead to a reduced protection against bacterial overgrowth, a phenomenon which is commonly observed in IBD (99, 100).

**Figure 8** Schematic overview of the differences in bile acid (BA) pool in healthy persons and IBD patients. In the healthy situation, BAs that escape the enterohepatic cycle are transformed by bacterial enzymes in the colon, leading to a normal BA pool that is dominated by secondary BAs. In IBD patients, dysbiosis leads to a reduced bacterial enzymatic activity, that results in a changed BA pool which is low in secondary BAs and high in conjugated and sulfated BAs.

## Aging and intestinal health

Interestingly, IBD pathogenesis shows multiple similarities with the aging process. For example, the aging process is also associated with intestinal dysbiosis, an impaired immune response and chronic inflammation (101). Moreover, both IBD and the aging process are important risk factors

for chronic diseases that affect the whole body. Hence, given the high similarities in underlying mechanisms, this could pose possibilities for sharing treating interventions. The aging process is associated with a functional decline of all organs and tissues in the body, including the intestinal tract (102). A commonly observed functional change of intestinal physiology include a prolonged transit time and increased prevalence of constipation (103). Moreover, the aging process is characterized by a decreased intestinal barrier function, an increase in low-grade inflammation (*inflammaging*) and a decline in immune response (*immunosenescence*) (104, 105) (**Fig. 9**).

**Figure 9** A schematic overview of the factors that impact intestinal health during aging. Red arrows implicate a detrimental effect on intestinal health, while green arrows could imply a positive effect on intestinal health in the aged population.

These factors are all known to alter gut microbiota composition (106). Many studies have been performed that investigated the differences in gut microbiota composition between young and old participants. Although often contradictory results have been observed, general age-related changes in gut microbiota composition include a decrease in alpha-diversity, a reduced abundance of beneficial bacteria (e.g. *Bifidobacteria* and *Lactobacilli*) (107, 108) and increased abundance of potential pathogens (e.g. members of the *Enterobacteriaceae* family) (109). Importantly, large interindividual variation was reported in elderly (110), which could pose difficulties in interpreting the

results. Regardless, it is clear that the gut microbiota play a role in age-related diseases. Therefore, manipulating the gut microbiota to reach a more beneficially composition could be a way to combat age-related diseases. Supplementation with prebiotics or probiotics could be such an approach. However, the outcomes on infection duration and inflammatory markers are rather inconsistent (111). Importantly, the effects of pre- and probiotics on health outcomes are largely dependent on a variety of factors, such as supplementation duration, way of administration, and the targeted health outcome. This emphasizes the need of highly controlled and targeted studies.

### ***In vivo* and *in vitro* models to investigate intestinal health**

The increased scientific interest to investigate intestinal health requires the use of representative, reliable, and reproducible study designs. For these studies, *in vivo* models using humans and animals are widely used. In the context of gut microbiota composition, human studies can be useful, but are often limited to the collection of fecal samples. However, the gut microbiota composition in feces is not completely representative for the luminal gut microbiota composition (112). To overcome this problem, newly developed techniques to sample luminal content in the intestine could be useful. In this regard, animal studies are valuable given the possibility to isolate not only organs and tissues, but also luminal content during sacrifice. Another advantage of animal studies is the possibility to perform genetic modifications, such as knocking out or down specific genes. This enables researchers to not only to investigate the molecular mechanisms of a gene of interest, but also to develop an animal model with a specific phenotype. For example, the use of the *Ercc1<sup>-/-Δ7</sup>* mouse model, which has an accelerated aging process due to a partial aberration of a DNA repair mechanism, is useful in aging research (113).

Important disadvantages of human and animal studies are the often expensive and lengthy study designs, but also ethical limitations, such as the exposure to potential harmful compounds and the isolation of tissues and organs. To overcome these limitations, *in vitro* models could be used as an alternative. A wide range of *in vitro* models exists and each has its own advantages and disadvantages. The most simple and cheap model includes a monoculture of intestinal epithelial cells, such as Caco-2 or T84 cells. To represent the intestine, these cells could be seeded on cell culture inserts that create an apical and basolateral compartment, representing the intestinal lumen and mucosal tissue, respectively. A disadvantage of using only one cell type is the lack of representativeness to the *in vivo* situation, as the intestine consists of several different cell types. Therefore, the monoculture grown on cell culture inserts could also be extended to a co-culture with

another intestinal cell type, such as the goblet-like cell type HT29-MTX (114). A major advantage of using mono- and co-cultures is the relatively easy, cheap, and quick applicability. Moreover, a second cell type can be added in the basolateral compartment, such as immune cells, which allows the inclusion of the immune system to the model.

A next level model of the intestine includes the use of *ex vivo* organ cultures, such as intestinal organoids. Intestinal organoids are the self-propagating spheres derived from intestinal stem cells (115, 116) or pluripotent stem cells (117). When grown in the presence of a basement membrane (i.e. Matrigel) and appropriate growth factors, intestinal stem cells will develop into a three-dimensional structure representing the *in vivo* organization of the intestine (118). Most often, organoid models make use of animal tissue (e.g. mouse, rat, pig), since human material is often more difficult to obtain. This may pose some difficulties in translating the results to the human situation. Another important issue is the fact that organoids are closed structures, which makes direct exposure to compounds of interest complicated. While it is possible to use microinjection techniques, this time-consuming technique restricts the performance of high-throughput studies. To overcome this limitation, organoids could also be seeded as two-dimensional monolayers, either on regular cell culture plates or cell culture inserts. Applying the right growing conditions results in a monolayer that recapitulates the *in vivo* intestinal epithelium in terms of cell type composition, crypt organization and tissue renewal rates (119).

Importantly, the described *in vitro* models are all static, while in the physiological situation, intestinal peristalsis causes a constant motion. An example of a dynamic cell culture system includes the gut-on-a-chip model, where a constant perfusion with cell culture medium generates a fluid flow that mimics the dynamic microenvironment found *in vivo* (120). The more sophisticated and extensive the model becomes, the more the costs increase. Furthermore, the setup of these models require detailed expertise and may therefore take a long time before the model is operational. It is, therefore, not evident that every researcher is able to use sophisticated organoid and gut-on-a-chip models, emphasizing the continuing popularity of the more accessible mono- and co-cultures.

## Outline of this thesis

In this thesis, a multiperspective approach was taken to investigate intestinal health. In daily life, the intestine is exposed to a wide range of potential factors that could impair intestinal health. As the intestine plays a key role in overall health, it is of utmost importance to keep this organ in a healthy state. A plethora of factors exist that have detrimental effects on intestinal health, which

may ultimately contribute to a decreased quality of life and increased healthcare costs. The aim of this thesis was to investigate how intestinal health is affected by the aging process, gut microbiota, and bacterial metabolites, such as bile acids. Furthermore, the increased interest in intestinal health research requires appropriate *in vitro* models representing the *in vivo* situation as close as possible. In this thesis, relevant *in vitro* models to investigate intestinal health are described.

It is known that the aging process has detrimental effects on intestinal health. As aging is an inescapable process, together with the fact that the life expectancy is increasing nowadays, it is important to 1) gain insight in the physiological and molecular changes that occur during aging, 2) investigate the mechanisms that are underlying these changes, and 3) seek strategies to improve healthy aging. In **Chapter 2**, we investigated changes in different parameters of intestinal health during the aging process in C57BL/6J mice. Feces and colonic luminal content of mice aged 6, 12, 24 and 28 months were subjected to gut microbiota composition analysis to investigate aging-related bacterial changes. Furthermore, differences in gut microbiota composition between fecal and colonic luminal content were elucidated. We also focused on aging-related changes in colonic gene expression and colonic luminal metabolites. Lastly, multivariate analyses were performed to integrate the gut microbiota composition and transcriptome datasets.

Given the frequently observed changes in gut microbiota composition during the aging process, approaches to manipulate the gut microbiota of the aged population could be a strategy to enhance healthy aging. A nutritional strategy could be the use of probiotics, including the supplementation of one or several health-promoting bacterial strains. In **Chapter 3**, the progeroid *Ercc1*<sup>Δ7</sup> mouse model was used to investigate the effects of supplementation of the promising health-improving probiotic strain *Akkermansia muciniphila* on intestinal health at high age. Special attention was given to the mucus layer, as *A. muciniphila* is a mucin-degrading bacterium with considerable effects on the mucus layer.

When investigating the aging process, it is remarkable to notice the similarities in disease pathogenesis with chronic diseases. For example, chronic (low grade) inflammation and decreased efficacy of the immune system are conditions that are also underlying a range of chronic inflammatory diseases, such as IBD. Moreover, microbial dysbiosis is an important hallmark of both the aging process as IBD. It is hypothesized that IBD-related dysbiosis plays an important role in disease aggravation that is modulated by microbial metabolites, such as BAs. Given the important physiological and regulatory functions of bile acids, bile acid dysmetabolism could have potential consequences on health. The increased abundance of fecal sulfated BAs in IBD patients is interesting, because this group of BAs has only been marginally investigated yet. In **Chapter 4**,

we aimed to investigate the effects of sulfated secondary bile acids on intestinal health. To this end, we designed an *in vitro* model representing the inflammatory situation as seen during IBD. After exposure to sulfated secondary bile acids, the effects on intestinal barrier function and immune response were investigated.

To be able to carry out high-quality research, appropriate study designs and models are required. There is a high interest in *ex vivo* and *in vitro* models representing the intestine. One of the important aspects with regard to intestinal health, the mucus layer, is often overlooked in existing *ex vivo* and *in vitro* models, since common cell culture methods are not appropriate to create a physiologically relevant mucus layer. Furthermore, the highly aqueous properties of mucus poses difficulties in the investigation and isolation of the mucus layer. In **Chapter 5**, we follow-up on a study that successfully increased mucus production in the HT29-MTX-E12 cell line by applying a semi-wet interface with mechanical stimulation (SWMS) method. We aimed to unravel the underlying (molecular) mechanisms of this increased mucus production by subjecting the cells to transcriptome analysis.

Finally, a general overview, a critical discussion of the data and evaluation of the current literature is given in **Chapter 6**.

## CHAPTER 2

# Integrative analysis of gut microbiota composition, host colonic gene expression and intraluminal metabolites in aging C57BL/6J mice

### Abstract

The aging process is associated with diminished colonic health. In this study, we applied an integrative approach to reveal potential interactions between determinants of colonic health in aging C57BL/6J mice. Analysis of gut microbiota composition revealed an enrichment of various potential pathobionts, including *Desulfovibrio* spp., and a decline of the health-promoting *Akkermansia* spp. and *Lactobacillus* spp. during aging. Intraluminal concentrations of various metabolites varied between ages and we found evidence for an increased gut permeability at higher age. Colonic gene expression analysis suggested that during the early phase of aging (between 6 and 12 months), expression of genes involved in epithelial-to-mesenchymal transition and (re)organization of the extracellular matrix were increased. Differential expression of these genes was strongly correlated with *Bifidobacterium* spp. During the later phase of aging (between 12 and 28 months), gene expression profiles pointed towards a diminished antimicrobial defense and were correlated with an uncultured *Gastranaerophilales* spp. This study demonstrates that aging is associated with pronounced changes in gut microbiota composition and colonic gene expression. Furthermore, the strong correlations between specific bacterial genera and host gene expression may imply that orchestrated interactions take place in the vicinity of the colonic wall and potentially mediate colonic health during aging.

## Introduction

Aging is a complex process characterized by a time-dependent loss of physical fitness accompanied by an increased risk of morbidities (1). The increase in life expectancy and the increased prevalence of age-related pathologies (1) demands further insight into the mechanisms underlying the aging process.

The colon is mainly involved in absorption of water and nutrients, but also plays an important role in general body health (2). Together with the small intestine, the colon constitutes the largest part of the whole-body immune system and is critical for an appropriate immune response towards the continuous exposure to potential inflammatory stimuli (3). One of the unique features of the colon is that it harbors a complex ecosystem of micro-organisms referred to as the gut microbiota. The gut microbiota is crucial for the development and maturation of the intestinal immune system during the early phase of life, as well as the maintenance of the intestinal epithelial barrier (4). Furthermore, the gut microbiota is involved in fermentation of non-digestible fibers and the production of short-chain fatty acids (SCFAs) (5), and as such lives in symbiosis with the host. In a healthy situation, the host is able to arrange an appropriate immune response upon microbial stimuli, which is non-responsive towards beneficial commensal bacteria, but reacts to pathogenic bacteria and restricts bacterial overgrowth (6, 7). However, aging is accompanied by a decline in function of the immune system and a chronic low-grade inflammation, known as immunosenescence and inflammaging, respectively (8). These factors, together with age-related changes in diet, lifestyle as well as colon physiology, inevitably trigger changes in gut microbiota composition (9). Alterations in gut microbiota composition have been linked to intestinal inflammatory diseases, as well as the development of other pathologies, e.g. metabolic syndrome, frailty and nervous system diseases (10-12). Thus, in the context of mechanisms underlying healthy aging, gaining knowledge on novel molecular interactions between gut microbiota and the host may be the key for the prevention and treatment of age-related pathologies.

Remarkable age-related changes in gut microbiota composition were observed in large human cohort studies (10, 13-15). However, interpretation of the data is complex because of a wide range of interfering lifestyle factors, including diet and medication, but also other factors, such as genetic background and place of residence. Furthermore, the microbiota composition in these studies was analyzed in faecal samples, while previous studies showed distinct bacterial populations in faeces and colon lumen (16-20). This observation rises the question whether the microbiota composition in fresh faeces is representative for the microbiota composition in the colon. Besides, when exploring the effects of the microbiota composition on colonic gene expression profiles, the analysis of the

colonic luminal content is preferred, because of its close proximity to the colonic wall. However, a major advantage of using faecal samples is the ability to investigate changes in gut microbiota composition during aging in a longitudinal manner.

To deepen our understanding regarding the effects of aging while limiting the effects of interfering factors, we generated an aging cohort of male C57BL/6J mice. These mice received a semi-synthetic diet, were individually housed and fresh faeces was collected from the same mice at 4, 8, 12, 18, 24 and 28 months for analysis of faecal microbiota composition. After sacrifice at 6, 12, 24 and 28 months of age, scrapings of the colonic wall were isolated to investigate colonic gene expression and colonic luminal content was collected for investigation of colonic microbiota composition and metabolomics analysis.

We hypothesized that the interaction between host and the gut microbiota will change during the aging process and might contribute to a decline in colonic health at old age. To obtain potential mechanistic insights that could explain transcriptional perturbations in response to changes in colonic microbiota composition during aging, or vice versa, we used a comprehensive integrative analysis to explore interactions between the gut microbiota and host colonic gene expression.

## **Materials and methods**

### **Ethics statement**

The institutional and national guidelines for the care and use of animals were followed and the Local Committee for Care and Use of Laboratory Animals at Wageningen University approved the experiment (code number: drs-2010151b).

### **Mice and study design**

In this study, 9-week old male C57BL/6J mice were housed individually and fed an ad libitum semi-synthetic (AIN-93W) diet. The study design was described previously in more detail (52). In order to study the aging process, mice were randomly distributed into four groups that were sacrificed at 6, 12, 24 and 28 months (n=11-16 mice per group). For 4 mice in the 24-months group and 5 mice in the 28-months group, fresh faeces were consecutively collected (directly after defecation) at the age of 4, 8, 12, 18, 24 and 28 months. Bodyweight and food intake were monitored bi-weekly. During sacrifice, the colon was opened and the colonic luminal content was collected first. Then, the middle part of the colon (~1 cm) was turned inside out, rolled and embedded in paraffin ('Swiss rolls') for histology. From the remaining colon parts, the mucosa and submucosa were scraped for RNA isolation. The

mice included in the present study were also used as control group for diet-intervention studies in the liver and colon of which the data have been reported in previous publications (21, 52-54).

### **Gut microbiota composition analysis**

For both fresh faeces (42 samples) and colonic luminal content (40 samples) the microbiota composition was determined. The detailed methods have been described previously (21). Briefly, DNA was isolated from faecal and colonic luminal content samples using the ZR Fecal DNA MicroPrep kit (ZYMO Research, Irvine, CA, USA) according to the manufacturer's instructions. Lysis of the samples was performed by bead beating using ZR BashingBead™ Lysis Tubes (ZYMO Research, Irvine, CA, USA). Next, the V3-V4 region of the 16S rRNA gene was amplified. After purification of the amplicon, DNA quality was checked and a second PCR was performed using sample-specific barcoded primers (Nextera XT index kit, Illumina, San Diego, CA, USA). Purified PCR products were sent to BaseClear service laboratory (BaseClear BV, Leiden, The Netherlands) for sequencing on the MiSeq platform (Illumina, San Diego, CA, USA). The Casava pipeline (version 1.8.3, Illumina, San Diego, CA, USA) was used for de-multiplexing of the FASTQ files. After initial quality control, three fresh faeces samples were excluded for further analysis, as the coverage was below threshold (50% of the median number of reads). CLC Microbial Genomics Module version 1.2.1 (CLC Bio, Qiagen, Aarhus, Denmark) was used for further analysis of the sequencing data. FASTQ files of the fresh faeces and colonic luminal content were imported and processed simultaneously. The identified OTUs were aligned against the Silva database (version 119) at 97% similarity (55). A number of 1,034,303 reads were detected, for which 1208 OTUs were identified. 25 of these OTUs (265 reads) were unavailable. Shannon entropy was considered as a metric for alpha-diversity and the beta-diversity was determined using Bray-Curtis distances. Principal Component Analyses and Redundancy analysis were carried out using Canoco 5 (56). The input consisted of the 303 OTUs with a relative abundance of  $\geq 0.1\%$  in at least one sample. With regard to the RDA, the numbers of reads were centered and standardized using the Hellinger transformation (57). The 16S rRNA gene data of this study have been made available in the sequence read archive (SRA) at the NCBI with accession number SRP145060.

### **Determination of metabolites in colonic luminal content**

The colonic luminal content of mice aged 6 months (n=6), 24 months (n=8) and 28 months (n=8) was prepared as described previously (21) and levels of metabolites were determined using <sup>1</sup>H-NMR. From the aligned spectra, integrals for SCFAs were identified. Besides, an untargeted approach

was taken to identify metabolites that differed between age groups. After baseline correction, the concentrations of the metabolites were calculated by taking into account the dilution factor and number of hydrogen atoms. Correlations between concentrations of identified metabolites and the relative abundances of the 50 most abundant genera in colonic luminal content were determined using Spearman's correlation.

### Gene expression analysis

For a number of 4 to 8 mice per age group, RNA was isolated from scrapings of the colonic wall and liver using TRIzol reagent (Invitrogen, Breda, The Netherlands). Isolated RNA was purified using RNeasy Micro columns (Qiagen, Venlo, The Netherlands) and total RNA yield (Nanodrop ND-1000, Nanodrop Products, Maarssen, The Netherlands) and RNA integrity (Agilent 2100 Bioanalyzer, Agilent Technologies, Amsterdam, The Netherlands) were measured. Only RNA was used that had a RNA integrity number (RIN) above 8.0 (**Supplementary Table S4**). Purified RNA (100 ng per sample) was converted to cDNA and labelled using an Ambion WT expression kit (Life Technologies, Bleiswijk, The Netherlands). Microarray hybridization and analysis was performed as previously described (52). Differences in gene expression between the age groups were analyzed using the Intensity Based Moderated T statistics (IBMT), using q-values <0.01 as threshold for the comparison 6 versus 12 months and p-values <0.01 for the comparison 12 versus 28 months. Microarray data has been submitted to the Gene Expression Omnibus (GEO) at the NCBI, and is accessible under number GSE113257. The Principal Component Analysis plot was generated using MultiExperiment Viewer version 4.9.0. Ingenuity Pathway Analysis (IPA) was used for identification of canonical pathways and upstream regulators (58). Gene Set Enrichment Analysis was performed to functionally interpret gene regulation (59). A false discovery rate (FDR) q-value of <0.1 was considered significantly enriched. Short Time-series Expression Miner (STEM) version 1.3.11 (60) was used to identify gene expression profiles during aging, using the mean Robust Multichip Average (RMA) values as input.

### Histology

Swiss rolls of 6 mice per age group were cut in 5 micrometer sections and mounted on microscope slides (VWR Superfrost Plus Micro Slide). The sections were dewaxed multiple times with xylene, rehydrated in alcohol and stained with Haematoxylin/Eosin (H&E) or Sirius red/Fast green. Pictures of the stained sections were taken using a microscope with Olympus CellSense Entry software (Olympus Europe, Hamburg, Germany). For the H&E stained sections, the depths of the colonic crypts were measured using Olympus Cell<sup>®</sup>B software.

### Multivariate analyses for gut microbiota and gene expression

In order to integrate colonic microbiota composition and colonic gene expression, we performed multivariate analyses in R 3.3.1 using the MixOmics package (61). Partial Least Squares (PLS) regression in the canonical mode was used to determine the bi-directional relationship between the two datasets. We used data from individual mice for whom both gene expression as well as the microbiota composition from colonic luminal content were available. For the MixOmics analysis early during aging (i.e. between 6 and 12 months of age), a number of 11 mice were included (6 months: n=4; 12 months: n=7). A number of 14 mice were included for the analysis using the genes differentially expressed between 12 and 28 months ( $p < 0.01$ ) (12 months: n=7; 28 months: n=7). The genera with a relative abundance of  $\geq 0.1\%$  in at least 1 sample were included, resulting in a number of 50 genera. First, the sequencing reads of the genera were transformed and zeros were imputed based on the centered log ratio (clr) using the aldx2 package with 1024 Monte Carlo permutations (62). Gene expression data were included after transformation into log2 RMA intensities. Relevance networks with the strongest positive and negative correlations ( $R < -0.8$  or  $R > 0.8$ ) were visualized using Cytoscape (63).

### Plasma measurements

Plasma levels of LBP were determined using the LBP ELISA Kit Mouse (kit OKBB00573, Aviva Systems Biology, San Diego, USA), following the manufacturer's protocol. Plasma samples were diluted 100 times. Plasma levels of insulin were determined using the Mouse Adipokine kit (MADKMAG-71K, Merck Millipore, Darmstadt, Germany), according to the manufacturer's protocol.

### Statistical analyses

Statistical analyses were, unless stated otherwise, carried out using GraphPad Prism 5.04 (GraphPad Software, San Diego, California, USA). The Kolmogorov-Smirnov test was used to test if data were normally distributed. In case of normal distribution, one-way analysis of variance (ANOVA) in combination with Tukey's multiple comparisons test was used to test for differences between ages. In case the data were not normally distributed, the non-parametric Kruskal-Wallis one-way analysis of variance following a Dunn's post hoc test and a Mann-Whitney test were used for independent samples. A Friedman test or Wilcoxon Signed Rank test were used in case samples were dependent. The Bonferroni or Benjamini-Hochberg approach were used to adjust for multiple testing, if appropriate. For all statistical tests, unless stated otherwise, a p-value of  $p < 0.05$  was considered as statistically significant.

## Results

### Physiological differences between mice during aging

Body weight as well as food intake increased during aging (**Figure S1A-B**). Also liver weight and relative liver weight (% of body weight) were significantly higher in older mice (**Figure S1C-D**). To determine if metabolic health altered during aging, fasting insulin levels in plasma were assessed. These levels were significantly increased at 24 and 28 months compared to 6 months ( $p < 0.01$ ) (**Figure S1E**). Death rates of the mice remained low till the age of 20 months and started to increase afterwards (**Figure S1F**). Most mice that died prematurely suffered from multiple conditions (**Data set S1**).

### Alterations in faecal and colonic microbiota composition during aging

Fresh faeces samples were collected longitudinally at 4, 8, 12, 18, 24 and 28 months of age in a subset of 9 mice. Sequencing of the V3-V4 region of the 16S rRNA gene revealed that the alpha-diversity, in terms of Shannon entropy, did not change during aging (**Figure 1A**). To explore variance in faecal microbiota composition, a Principal Component Analysis (PCA) on relative abundance of genera was performed. The PCA revealed that the first principal component, explaining 42.7% of the variation, separated the mice aged 4 and 8 months from the other age groups (**Figure S2A**). Dissimilarities in faecal microbiota composition between age groups were further investigated at two taxonomic levels. At the phylum level, the relative abundance of Proteobacteria was less abundant in young mice (4 months) and increased from 8 months onwards in most mice (**Figure 1B**). Verrucomicrobia and Actinobacteria were highly abundant at 4 months, but both disappeared in most mice between 4 and 12 months of life ( $< 1\%$ ). By exception, the relative abundance of Verrucomicrobia in mouse 9 at 28 months of age was high compared to the other mice at the same age (**Figure 1B**).

A

**Figure 1 Alterations in gut microbiota composition and metabolites during aging.** (A) The alpha-diversity measured by the Shannon entropy in fresh faeces. Boxes extend from the 25th to 75th percentile, line in the middle represents median, and whiskers represent minimum and maximum values. (B) Relative abundance (%) at phylum level in fresh faeces collected longitudinally in a subset of 9 mice. (C) The alpha-diversity measured by the Shannon entropy in colonic luminal content. (D) Principal Coordinate Analysis (PCoA) based on Bray-Curtis distances showing dissimilarities between all individual samples (FF and CLC). (E) The average relative abundance (%) at phylum level in colonic luminal content. Legend corresponds to graph with relative abundance at phylum level in fresh faeces. (F) Redundancy Analysis (RDA) displays the part of the variation in microbiota composition explained by the age groups and source. Sample plot showing the clustering of the samples. Legend corresponds to PCoA plot. The distance between the ages and sample sources approximates the average dissimilarity of the microbiota composition. The FF analyses were based on a subset of  $n=9$  mice at consecutive ages (4, 8, 12, 18, 24 and 28 months). For the CLC analyses,  $n=10$  mice per age group (6, 12, 24 and 28 months) were taken into account. (G) Levels of fumarate, (H) an unspecified bile acid and (I) methanol detected by  $^1\text{H}$ -NMR in CLC at 6 months ( $n=6$ ), 24 months ( $n=8$ ) and 28 months ( $n=8$ ) of age. Error bars represent standard error of the mean (S.E.M.). (J) Strongest Spearman correlation coefficients ( $-0.6 < r < 0.6$ ) for the concentrations of the identified metabolites and the relative abundances of the 50 most abundant genera in colonic luminal content.

Next to the analysis of the fresh faeces samples, the microbiota composition of the colonic luminal content of 40 mice sacrificed at the age of 6, 12, 24 and 28 months of age was investigated. Similar to the results obtained from the fresh faeces samples, no significant changes in Shannon entropy were found (**Figure 1C**) and the PCA revealed that the youngest and oldest age groups explained most of the variation (**Figure S2B**). These findings were strengthened by the distance-based Principal Coordinate Analysis (PCoA), since the first principal coordinate, explaining 27% of the variation, also separated young and old mice (**Figure 1D**). Comparison of the relative abundance at phylum and genus level between fresh faeces and colonic luminal content revealed mostly similar trends, although *Actinobacteria* phylum was hardly abundant in colonic luminal content (**Figure 1E**, **Table 1**, **Figure S3**). To investigate the impact of both age and source (fresh faeces and colonic luminal content) on the total variation, a Redundancy analysis (RDA) was performed. Ordination axis 1 explained 34.0% of the variation and separated the youngest age groups of both sources. Interestingly, ordination axis 2 explained 8.7% of the variation and separated the colonic luminal content and fresh faeces samples, indicating that the explanatory variable age contributed more to the variation in microbiota composition than the source variable (**Figure 1F**). Taken together, these results reveal pronounced changes in gut microbiota composition during aging, both in fresh faeces and more moderate in colonic luminal content. Additionally, subtle differences between the faecal and colonic microbiota composition were found.

### Metabolite profiles in colonic luminal content

To explore whether observed changes in gut microbiota composition may come with potential functional consequences, <sup>1</sup>H-NMR was performed in colonic luminal content at 6, 24 and 28 months of age. Concentrations of the SCFAs butyrate, propionate and succinate did not differ between the age groups, except for acetate that was significantly lower at 24 months compared to 6 months ( $p < 0.05$ ) (data not shown). Intraluminal concentrations of fumarate decreased during aging, as well as an unspecified bile acid (**Figure 1G-H**). It was not possible to exactly identify this bile acid, since this peak in the NMR spectrum (0.17 ppm) is located in a rather unexplored region. However, it can be ruled out that this is one of the bile acids as described by Kok and colleagues (21), since these bile acids were identified in a different region of the spectrum (0.6–0.8 ppm). The concentration of methanol increased in older mice (**Figure 1I**). A correlation analysis was performed to investigate whether the levels of these metabolites could be related to the relative abundances of the 50 most abundant genera. The strongest negative correlations were found for fumarate that was negatively correlated with the relative abundance of *Desulfovibrio* spp. ( $r = -0.651$ ), an uncultured *Ruminococcaceae* spp. ( $r = -0.708$ ) and an uncultured *Coriobacteriaceae* spp. ( $r = 0.681$ ), and positively correlated with *Parasutterella* spp. ( $r = 0.637$ ) (**Figure 1J**).

### Changes in colonic gene expression in 6, 12, 24 and 28-month-old mice

To explore the effect of aging on gene expression in the colonic wall, microarray analysis was performed on mRNA isolated from colonic scrapings from the same mice for which we also had data on the microbiota composition. A PCA carried out on the top 1,000 most variable genes revealed a clear segregation of the 6-months-old mice (**Figure 2A**). No clear separate clustering was observed for the mice from the other age groups, indicating that only gene expression at 6 months differed substantially from all other age groups. The highest number of significantly differentially expressed genes was found when comparing the youngest (6 months) versus the three older age groups (**Figure 2B**). There was a large overlap of genes ( $n = 610$ ) that had an increased expression when comparing 6 months with 12, 24 or 28 months (**Figure 2C**). Together, these results indicate that the expression levels of a substantial number of genes increased between 6 and 12 months, and remained increased also at higher ages.

**Table 1** Relative abundance of genera (abundance threshold  $\geq 0.1\%$  in a least one sample) that strongly changed ( $-10 > FC > 10$ ) in either fresh faeces (FF) and/or colonic luminal content (CLC) between young and old mice (FDR p-value  $< 0.1$ )

Number of mice: Fresh faeces 4M: n=8; 8M: n=6; 12M: n=7; 18M: n=8; 24M: n=8; 28M: n=5. Colonic luminal content 6M: n=10; 12M: n=10; 24M: n=10; 28M: n=10.

<sup>1</sup>Fold change (FC) of relative abundance in fresh faeces samples between young (4 months) and old (28 months) old mice. <sup>2</sup>A Wilcoxon Signed Rank Test and Kruskal-Wallis Test (performed in SPSS) for fresh faeces and colonic luminal content, respectively. The adjusted p-values are shown, corrected for multiple testing using the Benjamini-Hochberg method. A False Discovery Rate of 0.1 was considered as significant. <sup>3</sup>Fold change (FC) of relative abundance in colonic luminal content samples between young (6 months) and old (28 months) old mice.

### Dominant cluster of genes similarly expressed between 6 and 12 months

Visualization of the expression profiles of the 1,990 genes that were differentially expressed in the colonic wall of 6-months-old mice and the three older age groups (**Data set S2**) revealed a clustering of the majority of genes in four different expression profiles (**Figure 2D**). The profile in red contained by far the largest number of genes (817 genes) and showed the most prominent expression change between 6 and 12 months, remaining mostly stable afterwards (**Figure 2D**). The green profiles (602 genes in total) and the purple profile (217 genes) represent genes with decreased and increased expression levels during aging, respectively. Gene Ontology (GO) enrichment analysis of the green and purple profiles did not reveal any significant GO categories. However, analysis of the red profile revealed numerous significant GO categories that were all related to the extracellular matrix (ECM) organization and other structural development processes (**Table 2**). Ingenuity Pathway Analysis (IPA) and Gene Set Enrichment Analysis (GSEA) carried out on the genes differentially expressed between 6 and 12 months confirmed that similar pathways were affected (**Figure 2E** and **Table S2A**). IPA also revealed the 'Regulation of the Epithelial-to-Mesenchymal Transition Pathway' as a significantly regulated pathway in the colon between 6 and 12 months of age (**Figure 2E** and **Table S2C**). To analyze this aspect in more detail we assessed the expression regulation of genes involved in the epithelial-to-mesenchymal transition (EMT) in our microarray data set (**Table S2D**). Remarkably, while the expression of the epithelial markers E-cadherin (*Cdh1*), Occludin (*Ocln*) and most Claudins was minimally altered, the expression levels of the mesenchymal markers OB-cadherin (*Cdh11*), Vimentin (*Vim*), Fibronectin (*Fn1*) and Vitronectin (*Vtn*) (**Figure 2F** and **Table S2D**) were strongly increased between 6 and 12 months and remained constant afterwards. In addition, the same expression pattern was found for transcription factors associated with EMT, i.e. Snail Family Transcriptional Repressor 1 and 2 (*Snail*, 2), Zinc Finger E-Box Binding Homeobox 1 and 2 (*Zeb1*, 2) (**Figure 2F**), as well as other EMT-inducers, such as Transforming growth factor beta 1 (*Tgfb1*) and Transcription Factor 21 (*Tcf21*). IPA identified the transcription factor Transforming growth factor beta 1 (*Tgfb1*) as the strongest activated upstream regulator associated with differential gene expression between 6 and 12 months (**Table S2E**).

Error bars reflect standard error of mean (S.E.M.). \* $p < 0.05$ .

### Change in colon morphology during aging

To study the potential morphological consequences of the observed changes in ECM- and EMT-related genes we measured the colon length at sacrifice as well as colonic crypt depths in H&E-stained Swiss rolls. The obtained results revealed an increase in colon length during aging (**Figure 2G**). A marked deepening of the crypts between 6 and 12 months of age was observed, which minimally increased afterwards (**Figure 2H**). Furthermore, Sirius Red/Fast Green staining of the same Swiss rolls showed that the ECM protein collagen gradually increased with age (**Figure 2I**).

**Table 2** Top 5 most significant Gene Ontology (GO) categories (i.e. Biological Process, Molecular Function, Cellular Component) belonging to the red, purple and combined green profiles, as determined by STEM.

**Integrative analysis of microbiota composition and gene expression in the early phase of aging**

To obtain insight into the correlations between differential gene expression during the early phase of aging and the colonic microbiota composition, an integrative analysis was performed based on data of the individual mice. The 50 genera with a relative abundance of more than 0.1% in at least one sample and the 817 genes identified by STEM (**Figure 2D, red cluster**) showed several strong ( $r < -0.80$  or  $r > 0.80$ ) positive and negative correlations (top 25 strongest correlations shown in **Figure 3**). *Bifidobacterium* spp. was negatively correlated with 228 genes, including a cluster of EMT- and ECM-associated genes, e.g. *Cdh11*, *Fn1*, *Zeb1*, *Zeb2*, *Vim*, *Vtn* and *Fgfr1*, amongst others (**Figure 3** and **Data set S3**). Additionally, *Turicibacter* spp. and an uncultured member of the *Lachnospiraceae* family were positively correlated with a large number of genes, including Platelet Derived Growth Factor Receptor Beta (*Pdgfrb*), Wnt Family Member 2B (*Wnt2b*) and Gremlin 2 (*Grem2*), amongst others. Together, these results might imply the potential role of gut microbiota in the regulation of ECM (re)organization and EMT, or vice versa.

**Figure 3** Integrative analysis of microbiota composition and gene expression in the early phase of aging. The 817 up-regulated genes as determined by STEM were correlated with the 50 genera with a relative abundance  $\geq 0.1\%$  in at least 1 sample, including the mice aged 6 and 12 months. Relevance network showing the genera (white circles) and genes (grey rectangles) that were correlated ( $r < -0.80$  or  $r > 0.80$ ). Red lines represent positive correlations, blue lines represent negative correlations. Regarding the negative correlations, only the top 50 strongest negative correlations are shown for visualization purposes. Genes with green frames are involved in EMT and/or ECM-related processes. i.s.=incertae sedis; u.c.: uncultured.

### Aging-specific changes in colonic gene expression between 12 and 28 months

Next, we investigated alterations in gene expression during the later phase of the aging process by analyzing the changes between 12 and 28 months of age. Since the number of differentially expressed genes ( $n=170$ ,  $q < 0.01$ ) was too low to perform a functional analysis, a less stringent IBMT  $p$ -value  $< 0.01$  was applied to include genes displaying more subtle expression changes, resulting in 1,371 significantly differentially expressed genes (**Figure 4A**). The top 15 highest up- and down-regulated genes presented in **Table 3** show that Fatty acid binding protein 6 (*Fabp6*) had the strongest increased expression. The top 15 down-regulated genes were dominated by immune- and inflammatory-related genes, including 8 immunoglobulin-coding genes, Angiogenin 4 (*Ang4*), regenerating islet-derived 3 beta (*Reg3b*) and Resistin like beta (*Retnlb*). Another interesting immune-related gene displaying age-related reduced expression, but with a smaller fold change ranking them out of the top-15 list, was Indoleamine 2,3-dioxygenase 1 (*Ido1*) (**Data set S4**). The most significantly enriched down-regulated gene sets identified by GSEA were related to DNA replication and DNA synthesis (**Table S3B**). In addition, IPA identified 'Protein Ubiquitination Pathway', 'Mismatch Repair in Eukaryotes' and 'Cell Cycle Control of Chromosomal Replication' as most significantly regulated canonical pathways during the later phase of the aging process (**Figure 4B**).

and X-box binding protein 1 (Xbp1) as the strongest inhibited upstream regulator (**Table S3C**). Taken together, these results indicate that during the later phase of aging (between 12 and 28 months), gene expression profiles pointed towards a diminished antimicrobial defense, an altered protein degradation response and aberrations in DNA repair mechanisms.

**Figure 4** Aging-specific changes in colonic gene expression between 12 and 28 months and integration with colonic microbiota composition. **(A)** Number of differentially expressed genes between 12vs28, 12vs24 and 24vs28 months (IBMT  $p < 0.01$ ). **(B)** Top 10 most significant canonical pathways between 12 and 28 months identified by Ingenuity Pathway Analysis (IPA). Numbers behind bars represent the number of differentially expressed genes (IBMT  $p < 0.01$ ) and numbers behind the pathways represent the total number of genes. **(C)** Correlations between gut microbiota composition and gene expression during aging. The 1371 genes differentially expressed between 12 and 28 months were correlated with the 50 genera with a relative abundance  $\geq 0.1\%$  in at least 1 sample, including the mice aged 12 and 28 months. Relevance network showing the genera (white circles) and genes (grey rectangles) that were correlated ( $r < -0.80$  or  $r > 0.80$ ). Red lines represent positive correlations, blue lines represent negative correlations. For visualization purposes, only the top 25 strongest positive top 25 negative correlations are shown. i.s.=incertae sedis; u.c.: uncultured.

### Integrative analysis of microbiota composition and gene expression in the later phase of aging

A second integrative analysis was carried out to investigate the correlation between gene expression and gut microbiota composition during the late phase of life. For that purpose, the data of the 50 genera with a relative abundance of more than 0.1% in at least one sample and the 1,371 genes that were differentially expressed between 12 and 28 months (IBMT  $p < 0.01$ ) for each individual mouse were integrated. The highest number of most pronounced correlations ( $r < -0.80$  or  $r > 0.80$ ) was found for an uncultured member of *Gastranaerophilales* spp. (**Figure 4C**). *Pcdh16*, *Pcdh18* and *Abcg5*, all in the top 15 of strongest up-regulated genes (**Table 3**), as well as Ubiquitin Specific Peptidase 20 (*Usp20*), were negatively correlated with the relative abundance of this uncultured member. Interestingly, strong positive correlations ( $R \geq 0.75$ ) were found for the uncultured member of *Gastranaerophilales* spp. with the down-regulated immune-related genes *Ang4*, *Retnlb* and *Ido1* (**Data set S5**).

### Markers of gut permeability increased during aging

To determine whether there were changes in markers of gut permeability, concentrations of lipopolysaccharide-binding protein (LBP), a marker for bacterial endotoxins, were assessed in plasma of mice aged 6, 12, 24 and 28 months. LBP concentrations were significantly higher ( $p < 0.05$ ) in plasma from mice aged 28 months compared to 6-months-old mice (**Figure 5A**). Besides, the microarray data of the colonic wall revealed increased expression levels of the *Lbp* gene during aging (**Figure 5B**). LBP is also synthesized as an acute-phase protein in the liver and therefore we assessed expression levels of *Lbp* in liver tissue, which were increased during aging (**Figure 5C**). Interestingly, although we found increased plasma markers of gut permeability at higher age, there was no collective increase in expression of tight junction genes (**Data set S2**).

**Figure 5 Markers of gut permeability during aging. (A)** Concentrations of Lipopolysaccharide-binding protein (LBP) (ng/ml) in plasma. **(B)** Expression (Log2) of *Lbp* in the colon and **(C)** liver. \* $p < 0.05$

## Discussion

In the present study, we report that aging is associated with pronounced changes in gut microbiota composition and colonic gene expression. In agreement with the current literature, we found an increase in potential pathobionts and a decrease in health-promoting bacteria during aging, which could potentially contribute to the development of age-related pathologies (12, 22). In contrast to the mild effects of aging on colonic gene expression that we found several years ago (23), we now report much stronger effects, probably because we included older mice (28 months instead of 21 months of age). Moreover, by applying an integrative approach, we show that several bacterial genera strongly correlated with colonic gene expression, providing evidence for potential host-microbe interactions.

A unique feature of this study resides in the collection of fresh faeces at consecutive time points, allowing the observation of changes in microbiota composition during the life course in the same mouse. Because environmental circumstances were strictly controlled, a broad range of external factors could be disregarded, allowing us to focus primarily on aging-related changes. However, a limitation of the C57BL/6J mouse model in aging research is the increased vulnerability to premature hearing loss, impaired glucose tolerance and tumor formation, amongst others (24). Besides, it should be taken into account that differences exist in gut microbiota composition between mice and humans, mainly because of differences in size of the intestinal tract, metabolic rate and diet (25).

We found a strong increased relative abundance of *Desulfovibrio* spp. and *Bilophila* spp., two closely related genera that produce the potentially toxic compound hydrogen sulfide (26). It was previously shown that the relative abundance of *Desulfovibrio* spp. was increased in elderly humans compared to younger subjects (14). Furthermore, increased abundance of both *Bilophila* spp. and *Desulfovibrio* spp. has been associated with mucosal inflammation (26, 27), highlighting the presumable negative physiological consequences of an enrichment of these genera in the aged population. The increased relative abundance of these members of the gram-negative *Proteobacteria* could explain the significantly elevated plasma LBP levels at 28 months. LBP is an acute-phase protein that binds to LPS, resulting in an innate immune response (28). We suggest that the shift in gut microbiota composition during aging eventually caused a diminished intestinal barrier function that favored the translocation of LPS into the systemic circulation. We also found a higher relative abundance of *Odoribacter* spp. and *Turicibacter* spp. at higher age. These genera may be involved in colon tumorigenesis, since they were previously found to be enriched in tumor-bearing mice (29). Additionally, *Odoribacter* spp. was recently found to have a higher relative abundance in old compared to young mice (30). *Turicibacter* spp. was less abundant in humans with Alzheimer Disease compared to non-demented participants (31).

We found that the relative abundance of *Akkermansia* spp., *Bifidobacterium* spp. and *Lactobacillus* spp. decreased at middle-age, i.e. 8 months. Each of these genera has one or more health-promoting properties, such as the production of SCFAs, enforcement of the mucus layer and stimulation of the immune system (32-34). Previous studies reported a loss of these health-associated genera in aged mice and humans (35, 36), but our findings implicate that in mice, these genera disappear already at middle-age. It is important to note that *Akkermansia* spp. was shown to be negatively correlated with adiposity (37). Accordingly, the observed decrease in relative abundance of this genus could be related to an increase in bodyweight with age. *Coprococcus* spp., *Roseburia* spp. and *Christensenellaceae* spp., all described as producers of the health-promoting butyrate (38, 39), had increased relative abundances in old mice compared to young mice in our study. This runs contrary to humans studies in which these genera have shown lower relative abundance (14, 40) and that elderly persons had a gut microbiota composition reflecting a lower butyrate production capacity (41). However, *Christensenellaceae* spp. as well as *Akkermansia* spp. were detected in faeces of centenarians, i.e. people over 100 years of age (13, 14), implicating that these genera could be linked to an extreme life span. Although the oldest mice in our study could not be considered as representative for centenarians, their age was extremely high for mice (42), possibly explaining the presence of this genus. We found relatively low concentrations of intraluminal butyrate and other SCFAs, which is possibly the consequence of the low fiber semisynthetic diets that we used.

An uncultured *Coriobacteriaceae* spp. followed a strong decreasing pattern during aging. The *Coriobacteriaceae* family is a commensal community in the gut and some members play a role in several metabolic processes, such as bile acid metabolism (43). We did not find a strong correlation between the uncultured *Coriobacteriaceae* spp. with the level of the unspecified bile acid, but strong negative correlations were found with both fumarate and methanol. The relative abundance of *Parasutterella* spp., which decreased strongly during aging in our study, was also found to be significantly reduced in patients with colorectal cancer (44), but has not been reported in relation to aging yet. We found that this genus was positively correlated with fumarate and negatively correlated with methanol. Since both the uncultured *Coriobacteriaceae* spp. and *Parasutterella* spp. showed strong decreasing abundances during aging and were correlated with various metabolites, it would be worthwhile to further investigate the role of these genera and metabolites in the aging process. A recent study discovered that the bacterial metabolite colanic acid promoted longevity in the host *Caenorhabditis elegans* (45), emphasizing the importance of further studies to focus on the mediating role of bacterial metabolites during aging.

In this study, we collected both faecal and colonic samples, allowing us to investigate the similarity

in microbiota composition of both sample sources. Although age predominantly contributed to the variation in gut microbiota composition, we did observe subtle dissimilarities in relative abundances between sample sources. The most notable difference was the higher relative abundance of the *Actinobacteria* phylum in fresh faeces compared to colonic luminal content of young mice. A possible explanation for these dissimilarities is the fact that, in contrast to the colonic luminal content, fresh faeces passed the complete colon and may have been affected by various factors known to influence microbiota composition, such as oxygen levels and pH-values (16). The reliability of the use of stool samples for assessment of microbiota composition in human studies is currently under debate. However, the subtle differences detected between sample sources in the present study do not directly demand for a switch in using the relatively non-invasive stool samples to colonic content isolates in aging studies.

Remarkably, both the highly abundant *Akkermansia* spp. and *Desulfovibrio* spp. displayed a strong age-related decrease or increase, respectively, but did not show strong correlations with colonic gene expression. On the other hand, *Bifidobacterium* spp. was negatively correlated with a considerable number of genes related to ECM and EMT processes. Strong positive correlations were also found for *Turicibacter* spp. and two uncultured *Lachnospiraceae* spp. with the same subgroup of genes. Interestingly, the expression of mesenchymal markers and related transcription factors was strongly increased between 6 and 12 months, while expression of epithelial markers was not or moderately affected. These findings suggest that a change in cellular composition of the tissue occurs, in terms of a gain of a mesenchymal phenotype, but without loss of the epithelial phenotype. Conceivably, the EMT was not of classical nature and the step of de-epithelialization was eliminated, a process called partial or intermediate EMT (46). IPA identified *Tgfb1* as main upstream regulator which is a known and potent inducer of EMT during normal development, tissue repair, organ fibrosis and metastasis (47, 48). However, it is not plausible to assume that the observed EMT was pathological, since the mice remained in a healthy condition far beyond the time point at which the EMT was induced, and death rates remained extremely low till the age of 20 months. More likely, the EMT contributed to normal development of the mice that was possibly induced by certain gut microbiota, since we hypothesize that the presence of *Bifidobacteria* spp. (or its metabolites, e.g. lactic acid) could weaken the expression of ECM- and EMT-related genes, or vice versa. It was previously shown that pathogens do have the ability to activate EMT-signaling pathways (49), and our results could indicate that also non-pathogens might be involved in the regulation of these pathways. Next, we hypothesize that the gain in mesenchymal markers resulted in an increased deposition of ECM (48, 50), as confirmed by the collagen staining. Ultimately, these events could have led to a change in

colon morphology in our study, as observed by the increase in colonic crypt depth.

By exploring the changes between 12 and 28 months, we found evidence for an altered protein degradation response, together with a potential aberration of DNA repair mechanisms in the colon during the late phase of life. These processes are common events during aging and are linked to several age-related pathologies (1). Moreover, we observed a decreased intestinal immune response during aging, since several immunoglobulins, as well as the immunosuppressive *Ido1* gene, were strongly down-regulated. Besides, the strong down-regulation of *Ang4*, *Reg3b*, *Retnlb* and *Ido1* pointed toward a dysregulation of antimicrobial peptide expression at old age. Interestingly, *Ang4*, *Retnlb* and *Ido1* were positively correlated with an uncultured *Gastranaerophilales* spp. To the best of our knowledge, little is known about *Gastranaerophilales* spp., however, genome sequencing revealed that this order is capable of converting glucose, mannose, starch, or glycogen into lactate, ethanol and formate (51). Notably, the semi-synthetic diet fed to the mice in our study was rich in starch, possibly explaining the presence of this bacterial strain. *Usp20* was negatively correlated to the uncultured *Gastranaerophilales* spp., highlighting the possible role of this bacterial strain in the observed altered protein degradation response during aging.

Taken together, this study demonstrates that aging is associated with pronounced changes in gut microbiota composition and colonic gene expression, without interference of environmental factors. A presumably deleterious shift in gut microbiota composition occurred during aging, as we found an increase in potential pathobionts and a decrease in health-promoting bacteria. However, we also reported strong changes in relatively unexplored genera, which might have health effects during the aging process. Next to the pronounced differences in gut microbiota and colonic gene expression during aging, we also found strong correlations between these two aspects of colonic health. This finding implies that host-microbe interactions might play an important role during aging and therefore the newly identified molecular interactions should be investigated more extensively in future research.

Number of mice: Fresh faeces 4M: n=8; 8M: n=6; 12M: n=7; 18M: n=8; 24M: n=8; 28M: n=5. Colonic luminal content 6M: n=10; 12M: n=10; 24M: n=10; 28M: n=10.

<sup>1</sup>Fold change (FC) of relative abundance in fresh faeces samples between young (4 months) and old (28 months) mice. <sup>2</sup>A Wilcoxon Signed Rank Test and Kruskal-Wallis Test were performed in SPSS for fresh faeces and colonic luminal content, respectively. The adjusted p-values are shown, corrected for multiple testing using the Benjamini-Hochberg method. A False Discovery Rate of 0.1 was considered as significant. <sup>3</sup>Fold change (FC) of relative abundance in colonic luminal content samples between young (6 months) and old (28 months) mice.

**Table S2 (A)** Table including the top 10 of significantly enriched up-regulated and **(B)** down-regulated gene sets between 6 and 12 months, as determined by GSEA. **(C)** Genes included in the canonical pathways 'Hepatic Fibrosis/Hepatic Stellate Cell Activation' and 'Regulation of the Epithelial-Mesenchymal Transition Pathway' identified by IPA. **(D)** Expression of genes described to be up- or down-regulated during EMT, selection based on literature (see references in supplemental data). **(E)** IPA identified the top 5 upstream regulators with the highest activation score between 6 and 12 months.

## Abstract

### Background

The use of *Akkermansia muciniphila* as potential therapeutic intervention is receiving increasing attention. Health benefits attributed to this bacterium include an improvement of metabolic disorders and exerting anti-inflammatory effects. The abundance of *A. muciniphila* is associated with a healthy gut in early mid- and later life. However, the effects of *A. muciniphila* on a decline in intestinal health during the aging process are not investigated yet. We supplemented accelerated aging *Ercc1<sup>-Δ7</sup>* mice with *A. muciniphila* for 10 weeks and investigated histological, transcriptional and immunological aspects of intestinal health.

### Results

The thickness of the colonic mucus layer increased about 3-fold after long-term *A. muciniphila* supplementation and was even significantly thicker compared to mice supplemented with *Lactobacillus plantarum* WCFS1. Colonic gene expression profiles pointed towards a decreased expression of genes and pathways related to inflammation and immune function, and suggested a decreased presence of B cells in colon. Total B cell frequencies in spleen and mesenteric lymph nodes were not altered after *A. muciniphila* supplementation. Mature and immature B cell frequencies in bone marrow were increased, whereas B cell precursors were unaffected. These findings implicate that B cell migration rather than production was affected by *A. muciniphila* supplementation. Gene expression profiles in ileum pointed toward a decrease in metabolic- and immune-related processes and antimicrobial peptide production after *A. muciniphila* supplementation. Besides, *A. muciniphila* decreased the frequency of activated CD80<sup>+</sup>CD273<sup>-</sup> B cells in Peyer's patches. Additionally, the increased numbers of peritoneal resident macrophages and a decrease in Ly6C<sup>int</sup> monocyte frequencies in spleen and mesenteric lymph nodes add evidence for the potentially anti-inflammatory properties of *A. muciniphila*.

### Conclusions

Altogether, we show that supplementation with *A. muciniphila* prevented the age-related decline in thickness of the colonic mucus layer and attenuated inflammation and immune-related processes at old age. This study implies that *A. muciniphila* supplementation can contribute to a promotion of healthy aging.

## Introduction

Coincident with the increase in the aged population that is observed nowadays, the often inevitable decline in overall health in the elderly is becoming an alarming problem. The aging process is accompanied by a chronic low-grade inflammatory state, termed 'inflamm-aging', which is a strong risk factor for many age-related pathologies (1-4). One of the organs that is affected by the aging process is the intestinal tract and the occurrence of gut-related disorders in the aged population is considerable (5).

As main inhabitant of the intestine, the gut microbiota play an essential role in the maintenance of overall health. Bacteria are able to degrade complex carbohydrates, thereby converting these substrates into metabolites that are beneficial to health, such as short-chain fatty acids (SCFAs) (6, 7). Besides, the gut microbiota interact extensively with the host immune system by the regulation of immune responses (8). During the aging process, changes in gut microbiota composition occur, such as a decreased diversity, a decrease in health-promoting bacteria and an increase in potential pathobionts. This disturbed balance in microbiota composition is thought to increase the risk of impaired intestinal barrier function and intestinal inflammation (9). In mice, transfer of microbiota from aged mice to young germfree recipient mice promoted intestinal inflammation, increased leakage of bacterial components into blood and stimulated systemic immune activation (10).

An important factor with regard to gut health is the mucus layer that covers the intestinal epithelial cell layer and serves as physical protection for bacterial penetration and harmful compounds to enter the mucosal tissue (11). Intestinal mucus is built up of mostly Mucin 2 (Muc2) proteins, which are large gel-forming proteins that are secreted by goblet cells located in the intestinal mucosa. These proteins form a net-like structure and are the building blocks of the mucus layer. The importance of the mucus layer was emphasized in studies using Muc2 knockout mice, which did not have a colonic mucus layer covering the intestinal epithelial layer (12, 13). These mice suffered from a decreased intestinal barrier function, an increased inflammatory status (14) and had signs of colitis (12). Next to the protective function of the mucus layer, it also serves as an energy source for bacteria. *Akkermansia muciniphila* is one of the bacterial species that is able to degrade mucus. This bacterium is highly abundant (~3%) in the healthy human colon (15). Upon mucus degradation, *A. muciniphila* produces several immune-stimulating compounds, such as SCFAs and pili (16, 17). The outer membrane pili-like protein Amuc\_1100 is thought to be involved in the beneficial properties of *A. muciniphila* on health (18, 19).

Recent studies suggest that the beneficial effects of *A. muciniphila* are not limited to the intestinal tract, but extend to overall health. The abundance of *A. muciniphila* was reduced in people suffering

from obesity, type 2 diabetes, inflammatory bowel disease, amongst others (20). Furthermore, supplementation with *A. muciniphila* in mice resulted in an improved metabolic state and reduced diet-induced obesity (ClinicalTrials.gov Identifier: NCT02637115) (21-23).

We and others previously showed that the abundance of *Akkermansia* spp. in colonic luminal content decreased during aging in mice (10, 24, 25). Another study also reported an age-related loss of *Akkermansia* spp. in humans (26). Interestingly, the abundance of *Akkermansia* spp. was shown to be increased in centenarians (105-109 years old) compared to younger age groups (27). These results could indicate that a relation exists between reaching an extreme old age and the abundance of *Akkermansia* spp. (24, 27).

The numerous potential beneficial characteristics of *A. muciniphila* suggest that this bacterium could be a potent candidate for microbial supplementation. However, the effects of this bacterium on the decline in intestinal health as seen during aging are not widely investigated yet. Therefore, the aim of the present study was to investigate the effects of supplementation with *A. muciniphila* on different aspects of intestinal health. We used *Ercc1*<sup>-Δ7</sup> mice, an accelerated aging mouse model that has a median lifespan of ~20 weeks. Further characteristics of this mouse model were extensively described in previous studies (28-30) and indicate that the accelerated aging phenotype of *Ercc1*<sup>-Δ7</sup> mice largely resembles normal aging. The *Ercc1*<sup>-Δ7</sup> mice were supplemented with *A. muciniphila* for 10 weeks via oral gavage. After sacrifice, ileum and colon were subject to transcriptional analysis and the microbiota composition in these organs was investigated. Furthermore, we assessed mucus thickness in the colon and the distribution of immune cells in immune-related tissues.

## Materials and methods

### Mice and study design

In this study, accelerated aging *Ercc1*<sup>-Δ7</sup> mice were used. Genotyping of this mouse model was extensively described previously by others (28-30). In short, *Ercc1*<sup>-Δ7</sup> mice have an impaired DNA repair protein ERCC1, resulting in accumulation of a broad variety of DNA lesions and consequently accelerated aging. Mice were individually housed under SPF conditions, received an *ad libitum* purified diet (formula D12450B, Research Diets, **Additional file 5A**) and had *ad libitum* access to water supplied by water bottles with long nozzles. Mice were supplemented with *Akkermansia muciniphila* by oral gavage at a dose of 2x10<sup>8</sup> CFU/200 μL, three times a week, for a total of 10 weeks. Oral gavages were given in the morning. The control group simultaneously received oral gavages containing the same volume of PBS. A third *Ercc1*<sup>-Δ7</sup> mice group was included that received the

same dose of *Lactobacillus plantarum* WCFS1. These mice were only used for histological purposes. Growing procedures of the bacterial cultures was extensively described previously (29). A number of 18 mice per group (both male and female) was included and lifespan of these mice was assessed. After 10 weeks, when the mice were 16 weeks old, a number of 5-6 female mice were sacrificed. Colonic and ileal content, as well as distal ileum and proximal colon sections, were collected and snap-frozen in liquid nitrogen. A piece of ileal and colonic tissue was fixed in Carnoy's solution for histological purposes. Spleen, mesenteric lymph nodes, Peyer's patches, bone marrow and peritoneal exudate cells were isolated for immunological measurements.

### Histology

After paraffin embedding, Carnoy-fixed distal ileum and proximal colon tissue were sliced in 5 µm sections on poly-L-lysine coated glass slides (Thermo Scientific, Germany). Slides were dewaxed, dehydrated and stained with hematoxylin and eosin (H&E) and PAS/Alcian blue. The thickness of the colonic mucus layer was measured using ImageJ software (NIH, MD, USA). For comparison of the mucus layer thickness, we included an extra mouse group that received *Lactobacillus plantarum* WCFS1.

3

### Microbiota composition analysis

DNA was isolated from ileal and colonic content using a modified repeated bead beating method (50). Microbiota composition was assessed using 16S rRNA sequencing on the MiSeq platform (Illumina, San Diego, CA, USA). Next, the NG-Tax pipeline was used for barcode-primer filtering, de-multiplexing, OTU picking and taxonomic classification (51). The generated biom-files were used for summarizing the microbiological data, i.e. alpha-diversity and beta-diversity, using the R-packages microbiome (52) and phyloseq (53).

### RNA isolation

RNA was isolated from distal ileum and proximal colon tissue (n=5-6 mice/group) using TRIzol reagent (Invitrogen, Breda, The Netherlands). Purification of the isolated RNA was performed using the RNeasy Mini kit (Qiagen, Venlo, The Netherlands). After measurement of the total RNA yield (Nanodrop, ND-1000, Nanodrop Products, Maarssen, The Netherlands), RNA integrity was assessed (Agilent 2100 Bioanalyzer, Agilent Technologies, Amsterdam, The Netherlands) and only RNAs were included with a RNA integrity number (RIN) above 8.0.

### Microarray analysis

Microarray analysis was performed as described previously (54). Differences in gene expression between the control and *A. muciniphila* supplemented mice groups were assessed using the Intensity Based Moderated T statistics (IBMT) method, with p-values <0.05 and fold changes <-1.2 or >1.2. Microarray data has been submitted to the NCBI Gene Expression Omnibus (GEO) (GSE126730). Gene Set Enrichment Analysis (GSEA) was used to identify significantly enriched pathways (55). Only pathways with a False Discovery Rate (FDR) <0.2 were taken into consideration. Ingenuity pathway analysis (IPA) was used for the identification of upstream regulators (56).

### cDNA synthesis and real-time quantitative PCR

Real-time quantitative PCR (qPCR) was used to validate the expression profiles of a selection of differentially expressed genes identified in the microarray analysis. For both colon and ileum samples, complementary DNA (cDNA) was synthesized from 1000 ng of total RNA using the RevertAid First Strand cDNA Synthesis Kit (Thermo-Fisher Scientific, Landsmeer, The Netherlands) following the manufacturer's protocol. The following thermal cycling conditions were used: 5 min at 25°C, 60 min at 37°C and 5 min at 70°C. Primer sequences were obtained at the online PrimerBank database (**Additional file 5B**) (57). qPCR was performed with a CFX384 thermal cycler (Bio-Rad Laboratories, Veenendaal, the Netherlands) using the SensiMix SYBR No-ROX kit (Bioline, Alphen aan den Rijn, The Netherlands). The housekeeping gene 36B4 was used for normalization.

### Fluorescence-activated cell sorting (FACS) analysis

Spleen, mesenteric lymph nodes, Peyer's patches, bone marrow and peritoneal exudate cells were all subject to FACS analysis, similar as previously reported (29). In brief, femurs, tibias, ileac crests, forelegs, and sternum were harvested and crushed with mortar and pestle. Single-cell suspensions from each organ were prepared by passing cells through a 40-µm cell strainer with a syringe. First, cells were stained for extracellular markers. Fixable live/dead eFluor506 stain (Ebioscience, San Diego, USA) was used to exclude dead cells. Cells were fixed and permeabilized with Fix/Perm buffer (Ebioscience) to stain for intracellular markers. All antibodies used for flow cytometry are enlisted in **Additional file 5C**. A Canto II flow cytometer was used (BD Biosciences, Erembodegem, Belgium) and data analysis was performed using FlowJo vX.07 software (Tree Star Inc, USA).

### Statistical analysis

The Kolmogorov-Smirnov test was used to test if data were normally distributed and appropriate

non-parametric statistical tests were used when data were not normally distributed. With regard to the survival analysis, the log-rank (Mantel-Cox) test was used. To test differences between the control and supplemented group, a student t-test or Mann-Whitney U test was performed. With regard to the differences in mucus thickness, a Kruskal-Wallis test with Dunn's multiple comparisons test was performed, since three mouse groups were involved. Unless otherwise stated, p-value levels of  $p < 0.05$  were considered as statistically significant.

## Results

### *A. muciniphila* supplementation increased mucus thickness in colon of *Ercc1*<sup>Δ7</sup> mice

Since *A. muciniphila* is a mucus-colonizing bacterium and utilizes mucus as energy source, we investigated whether supplementation with *A. muciniphila* had an effect on the mucus layer in the colon of *Ercc1*<sup>Δ7</sup> mice. Measurements of mucus thickness in PAS/Alcian Blue stained colon tissue revealed that the mucus layer was significantly thicker in the mice supplemented with *A. muciniphila* compared to the control group ( $p < 0.001$ ) (**Figure 1A-C**). Besides, the results were compared with the mucus thickness of mice supplemented with *L. plantarum* (WCFS1), since we showed previously that supplementation with this bacterium prevented an age-related decline in mucus thickness (29). The colonic mucus layer of *L. plantarum* supplemented mice was thicker compared to the control group ( $p < 0.001$ ) (**Figure 1A, D**), but supplementation with *A. muciniphila* resulted in a significantly thicker mucus layer than the *L. plantarum* supplemented mice ( $p < 0.001$ ) (**Figure 1A**). These results show that supplementation with *A. muciniphila* contributed to the prevention of a decreased mucus layer thickness at old age.

**Figure 1 Mucus thickness increased in *Ercc1*<sup>-Δ7</sup> mice supplemented with *Akkermansia muciniphila*.** (A) Mucus thickness (µm) measured in colon of *Ercc1*<sup>-Δ7</sup> mice in the control, *A. muciniphila* group and *L. plantarum* group. (B) Representative picture of PAS/Alcian Blue staining in control mouse, (C) mouse supplemented with *A. muciniphila* and (D) *L. plantarum*. Data represent the mean + SEM from three to five mice per group. \*\*\* $p < 0.001$ . Scale bars histological images: 100 µm.

#### No differences in colonic and ileal microbiota composition after supplementation with *A. muciniphila*

In order to investigate whether supplementation with *A. muciniphila* caused changes in gut microbiota composition, we performed 16S rRNA gene sequencing on colonic and ileal content. Alpha-diversity (Shannon entropy) of colonic and ileal content samples did not differ between the control and supplemented mice (**Figure 2A**). To investigate whether supplementation with *A. muciniphila* resulted in an increased colonization of this bacterium, the relative abundance of *Akkermansia* spp. in colonic content was assessed. In colonic content, the average relative abundance was slightly higher in the intervention group ( $0.738 \pm 1.279\%$ ) compared to the control group ( $0.252 \pm 0.503\%$ ) (**Figure 2B**), but this difference was not statistically significant. *Akkermansia* spp. was not present in ileal content, except for one mouse in the intervention group (data not shown). Variation in microbial composition between samples was represented in a principal coordinates analysis (PCoA) based on Bray-Curtis dissimilarity. In both colon and ileum samples, no clear separation was observed between the control and *A. muciniphila* group (**Figure 2C-D**). Furthermore, no statistically significant differences at genus level between the control and supplemented mice was found in both sources (data not shown). These data show that bacterial supplementation with *A. muciniphila* three times a week did not result in changes in gut microbiota composition of *Ercc1*<sup>-Δ7</sup> mice.

**Figure 2 Microbiota composition in colon and ileum of *Ercct1*<sup>-Δ7</sup> mice supplemented with *Akkermansia muciniphila*.** (A) Alpha-diversity (Shannon entropy) measured in ileum and colon samples. Boxes extend from the 25th to 75th percentile, middle line represents median, and whiskers represent minimum and maximum values. (B) Relative abundance (%) of *Akkermansia* spp. in colonic content assessed by 16S rRNA sequencing. Data represent mean ± SEM (C) Beta-diversity measured by Bray-Curtis Principal Coordinate Analysis in colon samples and (D) ileum samples. Between four and six mice per group were used for microbiota analysis.

#### ***A. muciniphila* supplementation minimally altered the expression of genes involved in intestinal barrier function in colon**

To explore the effects of supplementation with *A. muciniphila* on gene expression, transcriptome analysis was performed on mRNA isolated from colon and ileum tissue of *Ercct1*<sup>-Δ7</sup> mice. In colon, a number of 427 genes was significantly differentially expressed ( $p < 0.05$ , fold change  $> 1.2$  or  $< -1.2$ ) between the control and *A. muciniphila* group, comprising 225 up-regulated and 202 down-regulated genes. Since a highly significant increase in mucus thickness was observed in the colon of mice that received *A. muciniphila*, colonic expression of genes related to mucus production was investigated. No significant differential expression of mucins was observed, except Mucin like 1 (*Muc1l*) which was down-regulated (-1.5-fold) in the *A. muciniphila* group compared to the control mice (**Additional file 1**). Besides, to explore if an increased mucus thickness in the colon resulted in an enhanced intestinal barrier function, expression of genes related to tight junction function was investigated. The classical tight junction proteins *Tjp 1-3*, *Jam 1-3*, *Claudin* family and *Ocln* were not differentially expressed (data not shown). To investigate which pathways were regulated in colon by *A. muciniphila* supplementation, Gene Set Enrichment Analysis (GSEA) was performed. Significantly enriched pathways were dominated by cell cycle related processes, but no pathways related to intestinal barrier function were observed (**Additional file 2**).

#### **Supplementation with *A. muciniphila* decreased expression of genes and pathways related to antimicrobial activities, metabolic processes and mucus biosynthesis in ileum**

Since supplementation with *A. muciniphila* minimally altered the expression of genes related to intestinal barrier function in colon, we also investigated gene expression profiles in ileum tissue of *Ercct1*<sup>-Δ7</sup> mice. A number of 795 genes was significantly differentially expressed ( $p < 0.05$ , fold change  $> 1.2$  or  $< -1.2$ ) between the control and *A. muciniphila* group in ileum, comprising 425 up-regulated and 370 down-regulated genes. Interestingly, several genes encoding for antimicrobial peptides were down-regulated in the *A. muciniphila* supplemented mice, i.e. *Reg3b* and *Reg3g*

(Figure 3A-B; Additional file 3). However, the expression of genes encoding for alpha-defensins and lysozymes was not affected by *A. muciniphila* supplementation. Tight junction genes were minimally differentially expressed, only *Cldn2* and *Cldn8* were down-regulated in ileum of mice supplemented with *A. muciniphila* compared to the control group (Figure 3C-D; Additional file 3). GSEA revealed that significantly enriched down-regulated pathways were dominated by metabolic processes (Additional file 2). Besides, the pathways “N-Glycan Biosynthesis” and “Biosynthesis of the N-Glycan Precursor (Dolichol Lipid-Linked Oligosaccharide, LLO) and Transfer to a Nascent Protein” were down-regulated in ileum of mice that received *A. muciniphila* supplementation compared to the control group (Additional file 2). Based on this finding, the microarray data set was searched for genes related to mucus biosynthesis. The genes *Ctnna3* and *St6galnac6* were down-regulated in ileum in the supplemented mice versus control group (Figure 3E-F; Additional file 3).

**Figure 3** Microarray analysis performed on mRNA isolated from ileum tissue. (A) Log2 microarray intensities of Regenerating islet-derived 3 beta (*Reg3b*), (B) Regenerating islet-derived 3 gamma (*Reg3g*) (C) Claudin 2 (*Cldn2*), (D) Claudin 8 (*Cldn8*), (E) Catenin (cadherin associated protein), alpha 3 (*Ctnna3*) and (F) ST6 (alpha-N-acetyl-neuraminyl-2,3-beta-galactosyl-1,3)-N-acetylgalactosaminide alpha-2,6-

sialyltransferase 6 (*St6galnac6*). Data represent mean + SEM. Control: n=5, *A. muciniphila*: n=6. \*p<0.05; \*\*p<0.01.

---

### Decreased expression of genes and pathways related inflammation and immune function in colon and ileum after *A. muciniphila* supplementation

As immune function is an important factor regarding intestinal health, expression profiles of genes related to immune response were investigated. Remarkably, down-regulated genes in both colon and ileum were dominated by genes encoding for immunoglobulins (**Additional file 1**). In the colon, several genes encoding for chemokines, such as *Cxcl13* (**Figure 4A; Additional file 3**) and *Ccl12*, as well as the cytokine *Il5* and the complement factors *C1ra* and *C5ar1* were all down-regulated (**Additional file 1**). Also the immunoglobulin receptor *Pilrb1* had a decreased expression in the colon of the *A. muciniphila* group (**Additional file 1**). Additionally, other immune-related genes were down-regulated in the colon of *A. muciniphila* supplemented mice compared to the control group, e.g. *Blk*, *Cd4*, *Cd72*, *Tlr7* and *Tlr12* (**Figure 4B-F; Additional file 3**). GSEA revealed that immune-related pathways were down-regulated in colon, for example “Intestinal Immune Network for IgA Production”, “Cytokine-Cytokine Receptor Interaction” and “Inflammatory Response Pathway”, amongst others (**Additional file 2**). Moreover, Ingenuity pathway analysis (IPA) identified seven cytokines as upstream regulators that were predicted to be inhibited after supplementation with *A. muciniphila*, including both the pro-inflammatory *Il1* and anti-inflammatory *Tgf-beta* (**Table 1**). Also other inflammation-related factors, such as Myeloid differentiation primary response 88 (*Myd88*), Tumor necrosis factor receptor superfamily member 1B (*Tnfrsf1b*) and 12 (*Tnfsf12*), NFKB Inhibitor Alpha (*Nfkbia*), T cell receptor (TCR) and Toll Like Receptor Adaptor Molecule 1 (*Ticam1*) were predicted inhibited upstream regulators (**Table 1**). In ileum, GSEA annotated the pathway “Antigen Presentation: Folding, assembly and peptide loading of class I MHC” as highly up-regulated (**Additional file 2**). The most significant upstream regulator identified by IPA in ileum tissue was Interleukin 10 Receptor Subunit Alpha (*Il10RA*), which was predicted to be slightly inhibited after *A. muciniphila* supplementation (**Table 2**). Taken together, these results show that *A. muciniphila* supplementation decreased the expression of numerous genes and pathways related to inflammation and immune function in both colon and ileum.

**Figure 4 Microarray analysis performed on mRNA isolated from colon tissue.** (A) Log2 microarray intensities of (A) C-X-C motif chemokine ligand 13 (*Cxcl13*), (B) B lymphoid kinase (*Blk*), (C) Cluster of differentiation 4 (*Cd4*), (D) Cluster of differentiation 72 (*Cd72*), (E) Toll-like receptor 7 (*Tlr7*), (F) Toll-like receptor 12 (*Tlr12*). Data represent mean + SEM. Control group: n=5. *A. muciniphila* group: n=6. \*p<0.05; \*\*p<0.01; \*\*\*p<0.001.

**Table 1** Upstream regulators in colon identified by Ingenuity pathway analysis based on the comparison between *Ercc1*<sup>-Δ7</sup> mice receiving *A. muciniphila* supplementation and control mice. Cut-off values include p<0.05 and activation z-score <-1.2 or >1.2. Upstream regulators in bold are involved in inflammation- and immune-related processes.

### Minor changes in local B cell distribution after *A. muciniphila* supplementation

Based on the findings of the microarray analysis, we continued with the investigation of immune cell distribution in different organs of the immune system. Since several B cell related genes were down-regulated after *A. muciniphila* supplementation, such as immunoglobulin genes (both in ileum and colon), and *Blk* (only in colon), we first focused on the local distribution of B cells. In mesenteric lymph nodes (MLN) and Peyer's patches (PP), no differences in B cell frequencies between groups were observed (**Figure 5A-C**). However, in PP the frequency of activated CD80<sup>+</sup>CD273<sup>-</sup> B cells was significantly lower in the supplemented mice ( $p=0.009$ ) (**Figure 5D**). Furthermore, frequencies of more immature CD80<sup>-</sup>CD273<sup>-</sup> B cells were significantly higher in the *A. muciniphila* group ( $p=0.03$ ) (**Figure 5E**), whereas no changes were observed in CD80<sup>+</sup>CD273<sup>+</sup> memory-like and CD80<sup>-</sup>CD273<sup>+</sup> B cells (**Figure 5F-G**) (31).

**Figure 5 Distribution of B cell subsets in mesenteric lymph nodes (MLN) and Peyer's patches (PP) after supplementation with *Akkermansia muciniphila*.** (A) Mean frequency of B cells in MLN. (B) Flow cytometric analysis of B cells in PP. (C) Mean frequency of B cells in PP. (D) Mean frequency of CD80<sup>+</sup>CD273<sup>-</sup> B cells, (E) CD80<sup>-</sup>CD273<sup>-</sup> B cells, (F) CD80<sup>+</sup>CD273<sup>+</sup> B cells and (G) CD80<sup>-</sup>CD273<sup>+</sup> B cells in PP. Data represent the mean + SEM from five to six mice per group. \*p<0.05; \*\*p<0.01.

#### ***A. muciniphila* supplementation increased the migration of B cells into spleen and BM**

Next, we continued with investigation of B cell subsets in spleen and bone marrow (BM). The frequency of total B cells in spleen was not different between groups (**Figure 6A**). Also other B cell subsets in spleen, such as immature, follicular and marginal zone B cells, were not significantly different between groups (data not shown). However, the frequency of B1 cells in spleen was significantly higher in the *A. muciniphila* mice (p=0.02) (**Figure 6B-C**). In bone marrow (BM), a trend of higher frequencies of total B cells was observed in *A. muciniphila* supplemented mice compared

to control mice ( $p=0.07$ ) and frequencies of mature and immature B cells were also higher ( $p=0.02$  and  $0.06$ , respectively) (**Figure 6D-G**). Frequencies of B cell precursors, i.e. pro-B cells, small resting pre-B cells and large cycling pre-B cells were not different between groups (**Figure 6H-J**). These data suggest that *A. muciniphila* supplementation did not change production of new B cells in BM, but increased migration of B cells into the spleen and BM.

**Figure 6 Distribution of B cell subtypes in spleen and bone marrow (BM) after supplementation with *Akkermansia muciniphila*.** (A) Mean frequencies of CD19<sup>+</sup>CD3<sup>+</sup> B cells in spleen. (B) Flow cytometric analysis of live single CD19<sup>+</sup>CD3<sup>+</sup> cells in spleen. (C) Mean frequencies of CD5<sup>+</sup>CD43<sup>+</sup> B1 cells in spleen. (D) Mean frequencies of B cells in BM. (E) Flow cytometric analysis of live single CD19<sup>+</sup> cells, divided in pro-B cells, large cycling pre-B cells and small cycling pre-B cells in BM. (F) Mean frequencies Mature B cells, (G) Immature B cells, (H) Pro-B cells, (I) Small resting pre-B cells and (J) Large cycling pre-B cells in BM. Data represent the mean + SEM from four to six mice per group. \*p<0.05.

#### T cell distribution in MLN and spleen unaltered after *A. muciniphila* supplementation

Transcriptome analysis showed that expression of the *Cd4* gene was decreased in the colon of mice that received *A. muciniphila* compared to the control mice. Moreover, IPA revealed T cell receptor (TCR) as predicted inhibited upstream regulator in colon. Therefore, we investigated whether the distribution of T cells was altered between groups in spleen and MLN. However, CD4<sup>+</sup> and CD8<sup>+</sup> T cell distributions in MLN and spleen were not different compared to the control group, neither were

CD4<sup>+</sup>FoxP3<sup>+</sup> Treg frequencies changed in both immune tissues (**Figure 7A-F**).

**Figure 7** Distribution of T cells in mesenteric lymph nodes (MLN) and spleen after supplementation with *Akkermansia muciniphila*. **(A)** Mean frequencies of CD4<sup>+</sup> T cells and **(B)** CD8<sup>+</sup> T cells and **(C)** FoxP3<sup>+</sup> Treg cells in MLN. **(D)** Mean frequencies of CD4<sup>+</sup> T cells and **(E)** CD8<sup>+</sup> T cells and **(F)** FoxP3<sup>+</sup> Treg cells in spleen. Data represent the mean + SEM from five to six mice per group.

### Decreased inflammatory cell populations in spleen and MLN after *A. muciniphila* supplementation

Next, since GSEA revealed an enrichment of pathways related to inflammatory response and immune function, we investigated whether inflammatory cell frequencies were altered after supplementation of *Ercc1*<sup>-Δ7</sup> mice. In spleen, the frequencies of total and Ly6C<sup>hi</sup> monocytes were slightly lower in the *A. muciniphila* group and Ly6C<sup>int</sup> monocytes were significantly lower ( $p=0.01$ ) (**Figure 8A-D**). Besides, the frequency of neutrophils was also slightly lower in the supplemented mice (**Figure 8E**). The same

trends of these inflammatory cell populations were found in MLN, although cell frequencies were low (<1%, data not shown). These data reveal a minor decrease in inflammatory markers in spleen and MLN after *A. muciniphila* supplementation in *Ercc1<sup>-Δ7</sup>* mice. In addition, we assessed if we could identify any signs of immune cell infiltration by investigating H&E stained tissue. For both colon and ileum tissue, no histological signs of immune infiltration were observed in the control and *A. muciniphila* group (**Figure 8F**).

**Figure 8** Distribution of inflammatory cell frequencies in spleen after supplementation with *Akkermansia muciniphila*. (A) Mean frequencies of total CD11b<sup>+</sup>CD68<sup>+</sup> monocytes. (B) Flow cytometric analysis of live single CD11b<sup>+</sup> Ly6C/CD68 cells, divided in Ly6C<sup>hi</sup>, Ly6C<sup>int</sup>, Ly6C<sup>lo</sup> monocytes and CD68<sup>dim</sup>Ly6C<sup>int/hi</sup> neutrophils. (C) Mean frequencies of Ly6C<sup>hi</sup> (D) Ly6C<sup>int</sup> monocytes and (E) neutrophils. (F) Representative picture of H&E stained colon and ileum tissue of control and *A. muciniphila* supplemented mouse. Data represent the mean + SEM from five to six mice per group. \*p<0.05.

### Increased numbers of CD11b<sup>+</sup> cells and resident macrophages in peritoneum of *Ercct1*<sup>Δ7</sup> mice supplemented with *A. muciniphila*

Since we found a higher abundance of B1 cells in spleen and this cell type is generally highly enriched in the peritoneal cavity, we also investigated the distribution of immune cells in the peritoneum. Remarkably, the total number of peritoneal cells in mice supplemented with *A. muciniphila* was nearly 3-fold higher than in the control mice (p=0.02) (**Figure 9A**). The absolute numbers of B cells, B1 cells and T cells did not significantly differ between groups (**Figure 9B-D**). We found an increase in absolute numbers of CD11b<sup>+</sup> cells in the peritoneum after *A. muciniphila* supplementation (p=0.004) (**Figure 9E**). Investigation of CD11b<sup>+</sup> cell subsets revealed that absolute numbers of neutrophils were not significantly higher after *A. muciniphila* supplementation (**Figure 9F**), in contrast to resident macrophages (p=0.045) (**Figure 9G-H**). In addition, the expression of CD115 on resident macrophages was significantly higher in the *A. muciniphila* group compared to the control group (p=0.02) (**Figure 9I**), whereas no change in the expression of CD11b and SIRPα was observed (**Figure 9J-K**).

**Figure 9** Distribution of immune cells in the peritoneum after supplementation with *Akkermansia muciniphila*. **(A)** Absolute number of total peritoneal exudate cells (PEC), **(B)** CD3-CD19+ B cells, **(C)** CD5+CD43+ B1 cells and **(D)** CD3+ T cells, **(E)** CD11b+ cells and **(F)** CD11b+Ly6G+ neutrophils. **(G)** Flow cytometric analysis of CD11b+ cells. **(H)** Absolute numbers of CD11b+Ly6G- resident macrophages in peritoneal exudate cell suspension. **(I)** Median Fluorescence Intensity (MFI) of CD115 marker, **(J)** CD11b marker and **(K)** SIRPa marker expressed on resident macrophages. Data represent the mean + SEM from five to six mice per group. \*p<0.05; \*\*p<0.01.

#### ***A. muciniphila* supplementation did not alter survival, body weight and organ weights in *Ercc1*<sup>Δ7</sup> mice**

Supplementation with *A. muciniphila* for 10 weeks did not alter survival rates as compared to the control mice (**Additional file 4**). Body weight of *Ercc1*<sup>Δ7</sup> mice increased in the first half of life, but decreased again from 11 weeks of age onwards (**Additional file 4**). No pronounced differences in body weight development were found between groups. The weight of liver, spleen and thymus measured directly after sacrifice were not significantly different between control and *A. muciniphila* group (data not shown).

### **Discussion**

The bacterium *Akkermansia muciniphila* is suggested to be a promising microbial supplement, due to its beneficial effects on health (20, 32). However, its effects on the decline in intestinal health during aging are not well investigated yet. In the present study, we investigated the effects of supplementation with *A. muciniphila* on different aspects of intestinal health in accelerated aging *Ercc1*<sup>Δ7</sup> mice. We report that supplementation with *A. muciniphila* for 10 weeks resulted in a significantly thicker colonic mucus layer and an improvement of anti-inflammatory immune status compared to the control group.

In two recent studies, it has been shown that the colonic mucus layer decreased in aging mice, suggesting an association with bacterial penetration and immune activation (29, 33). An aging-related decrease in mucus thickness was also observed in *Ercc1*<sup>Δ7</sup> mice (29), confirming the similarity in aging phenotype in this accelerated aging mouse model compared to a mouse model with a normal aging process. We previously showed that *L. plantarum* WCFS1 increased the thickness of the colonic mucus layer in *Ercc1*<sup>Δ7</sup> mice (29), but we now show that *A. muciniphila* is capable to even further thicken the mucus layer. The ability of *A. muciniphila* to increase mucus thickness was also reported before (23). *A. muciniphila* is able to degrade mucin structures to use it as carbon and nitrogen source and is therefore called a mucus-degrader (17). Nevertheless, the observed increased mucus layer thickness after supplementation suggests that this bacterium is able to actively turn on host colonic mucus production, a suggestion that has also been made by Derrien and colleagues (34). Interestingly, we did not find differential expression of any genes encoding for mucins, apart from a down-regulation of *Muc1* in colon tissue. However, expression levels of this gene were low and it is not a typical mucin that constitutes the colonic mucus layer, such as *Muc2* (35). In our previous study, supplementation with *L. plantarum* WCFS1 did neither result in differences in mucin

gene expression, while significantly increased colonic mucus thickness was observed (29). Possibly, supplementation with *A. muciniphila* resulted in an increased mucus thickness by impacting mucus biosynthesis processes without affecting *Muc2* expression. In order to understand the exact underlying mechanisms of the mucus turnover processes, further investigation is warranted.

Interestingly, in the ileum of *A. muciniphila* supplemented mice, GSEA revealed a down-regulation of two pathways related to N-Glycan biosynthesis and besides, two genes related to mucus biosynthesis were also down-regulated. These results imply that, besides its great impact on the colonic mucus layer, *A. muciniphila* could also have had an effect on the ileal mucus layer. We could not verify this finding by measuring the ileal mucus layer, because of its rather discontinuous appearance due to the presence of villi.

Next to the important function of the mucus layer, tight junctions (TJs) sealing the intestinal epithelial cells also play an important role in intestinal barrier function and an age-related decreased expression of TJ genes was found in baboons (36). We and others previously showed that *A. muciniphila* improved intestinal barrier function in a Caco-2 cell model (37) as well as in mice (18, 19, 23, 38, 39). In the present study, we found a down-regulation of *Cldn2* and *Cldn8* in the ileum of *A. muciniphila* supplemented mice. However, the intestinal barrier consists of a complex structure of multiple protein networks (40). Therefore, it is not possible to draw any solid conclusions on the effects of *A. muciniphila* supplementation on intestinal barrier function based on gene expression data only.

Gut microbiota composition and bacterial diversity in ileum and colon were not significantly changed after supplementation with *A. muciniphila*. This result indicates that bacterial supplementation with *A. muciniphila* does not lead to a reshaped gut microbiota composition, which was also reported before (23). Gut microbiota analysis revealed that the relative abundance of *A. muciniphila* was low in ileal and colonic content. It was previously shown that *Akkermansia* spp. was more present in colon than ileum in mono-colonised mice (39), but the low abundance in colon was remarkable. The dose of the bacterium, i.e.  $2 \times 10^8$  CFU for 3 times a week, was already proven effective in previous mice studies (23). Possibly, the relatively long time between the last oral gavage and sacrifice (about 24 hours) could have led to a washout of *A. muciniphila*. Though, a recent study showed that daily supplementation with 11 probiotic strains resulted in low colonization in mice which was caused by the indigenous microbiome (41). Possibly, this finding may also explain the impeded colonization of *A. muciniphila* in our study.

Bacterial supplementation with *A. muciniphila* resulted in a down-regulation of numerous immune-related genes and pathways in colon. Notably, these included several B cell related genes, such as

immunoglobulins, *Blk* and *Pilrb1*, amongst others. Moreover, GSEA revealed a down-regulation of the pathway "Intestinal immune network for IgA production". These results imply that *A. muciniphila* supplementation may have decreased the necessity for producing IgA, i.e. exerting a mucosal protective reaction against commensal bacteria (42). In line with these results, we found a down-regulation of both *Tlr7* and *Tlr12* in colon. However, we could not confirm this hypothesis, since IgA concentrations in colon were not measured during this study. We did investigate B cell frequencies in several immune tissues. Nevertheless, we could not find differences in B cell frequencies in MLNs, whereas B cell frequencies were increased in spleen and BM. These findings suggest that based on transcriptome analysis, *A. muciniphila* decreased B cell frequencies and CD4<sup>+</sup> T cells in colon and caused a potential redistribution of B and T cells among lymphoid organs. Conversely, frequencies of total B cell subsets in BM and spleen were slightly increased after *A. muciniphila* supplementation, with no change in B cell precursor frequencies in BM. These findings may indicate that supplementation with *A. muciniphila* inhibited influx of B cells into the colon, leading to a slightly increased mature B cell pool in spleen and BM.

Furthermore, we found a decrease in inflammatory markers in colon after *A. muciniphila* supplementation. Several genes encoding for chemokines, complement factors, as well as the cytokine *Il5* were down-regulated after *A. muciniphila* supplementation. Besides, IPA identified numerous pro-inflammatory cytokines as potentially inhibited upstream regulators in colon. The anti-inflammatory properties of *A. muciniphila* are already extensively described (34). We now add evidence that *A. muciniphila* might protect against the aging-related increase in inflammation (inflamm-aging) by decreasing the colonic expression of pro-inflammatory genes and pathways. Besides, we also identified the anti-inflammatory cytokine Tgf-beta as inhibited upstream regulator. Although we only found one anti-inflammatory cytokine, this finding may point toward a general reduction of immune activation by *A. muciniphila*. Histological analysis of the colon did not reveal any clear signs of immune infiltration in both groups. In a previous study by Derrien and colleagues, an up-regulation of immune related genes with no signs of microscopically visible inflamed tissue was also observed in mice mono-colonized with *A. muciniphila* (39). The authors suggest that these observations were part of regulatory processes of immune tolerance toward *A. muciniphila*. However, in this study germ-free mice were used, hence any comparisons between these particular results and our results should be made with caution.

Interestingly, we found significantly lower frequencies of activated B cell subtypes and higher frequencies of more immature B cell subtypes in PP. The increased level of inactive immature B cells is in accordance with the microarray results from ileum tissue, since we also found decreased

expression of numerous immunoglobulin-related genes. Besides, *Reg3b* and *Reg3g* were both down-regulated in ileum. We previously showed that *A. muciniphila* supplementation also decreased *Reg3g* expression in ileum of mice fed a high-fat diet (19). In a recent study, an increased expression of antimicrobial genes was found in the ileum of aged C57BL/6 mice, including *Reg3b*, *Reg3g*, *Defb1* and *Retnlb*, which was suggested to be related to an increased state of epithelial distress (43). Hence, based on our findings we suggest that supplementation with *A. muciniphila* might contribute to prevention of the age-related state of epithelial distress in ileum.

It is well-known that T cell function declines during the aging process (44). Our previous study revealed that supplementation with *L. plantarum* WCFS1 and *L. casei* BL23 increased regulatory T cell frequencies in MLN of *Ercc1*<sup>-Δ7</sup> mice. However, supplementation with *A. muciniphila* did not lead to any changes in T cell distribution in MLN, spleen and PP, despite a down-regulation of the *Cd4* gene in colon and the predicted inhibition of the upstream regulator TCR. Possibly, the increased colonic mucus layer caused by *A. muciniphila* supplementation resulted in an increased protective state in the colon, thereby decreasing the production of a number of T cell attracting chemokines and subsequently leading to a decrease of CD4<sup>+</sup> T cell attraction and infiltration.

In the peritoneal cavity, a highly significant increase in resident macrophages was observed after *A. muciniphila* supplementation. Peritoneal macrophages are important in the modulation of immune responses during infections and contribute to tissue homeostasis (45). Furthermore, peritoneal resident macrophages were shown to defend against microbial invasion (46), which could explain the high presence of this cell type after a supplementation with *A. muciniphila*. However, this increase in peritoneal resident macrophages was not coincided with increased frequencies of neutrophils and T cells, while these cell types are expected to be highly present during inflammation. This observation implies that supplementation with *A. muciniphila* resulted in an activated state with regard to peritoneal resident macrophages, but resulted in an anti-inflammatory rather than a pro-inflammatory response.

## Conclusion

The attention for *A. muciniphila* as a potential microbial supplement has increased and ample evidence exists emphasising the beneficial effects of this bacterium on low-grade inflammation and (cardio)metabolic disorders (16, 20, 34, 47). In the present study, we also observed that several metabolic processes in ileum, as well as immunological processes in both ileum and colon were affected by *A. muciniphila*, but now in an aging model. Furthermore, we convincingly showed that

*A. muciniphila* has a protective effect against an age-related decline in mucus thickness, which was even stronger compared to *L. plantarum* WCFS1. Aging is often accompanied by low-grade inflammation and an increased risk on metabolic syndrome (1, 48), contributing to a decreased quality of life and a considerable rise in healthcare costs (49). Our study showed a causal relationship between *A. muciniphila* and attenuation of the aging phenotype, in terms of preventing the age-related decline in thickness of the colonic mucus layer and improving immune status. These results therefore support the therapeutic application of *A. muciniphila* in the aging population and pave the way for further studies investigating *A. muciniphila* as therapeutic intervention contributing to healthy aging. Further research should focus on the practical aspects for application in humans, such as the dosage, frequency and way of administration.

### List of abbreviations

BM, bone marrow; CFU, colony-forming unit; *Ercc1*<sup>-Δ7</sup> mice, mice with defective nucleotide excision repair gene *Ercc1*; FACS, fluorescence-activated cell sorting; FC, fold change; FDR, false discovery rate; GSEA, gene set enrichment analysis; H&E, hematoxylin and eosin; IBMT, Intensity based moderated T statistics; IPA, Ingenuity pathway analysis; MLN, mesenteric lymph node; PAS, periodic acid-Schiff; PCoA, principal coordinates analysis; PP, peyer's patches; qPCR, quantitative polymerase chain reaction; SPF, specific pathogen-free; TJ, tight junction.

### Acknowledgments

We would like to thank Floor Hugenholtz for her help during 16S rRNA sequencing and Jenny Jansen for her help during microarray performance. We would also thank Jan Hoeijmakers for his excellent work on conceiving the *Ercc1*<sup>-Δ7</sup> mouse model. Yvette van Loon is acknowledged for her help with breeding and genotyping the mouse cohorts.

### Funding

This work was funded by the Netherlands Organization for Scientific Research (Spinoza Award and SIAM Gravity Grant 024.002.002) and through the NWO Graduate Programme on Food Structure, Digestion and Health.

### Ethics approval

Experiments were performed with the Principles of Laboratory Animal Care and with Dutch legislation and approval of the Dutch Ethical Committee of Wageningen.

### Availability of data and material

Microarray data are available in the NCBI Gene Expression Omnibus (GEO) with number GSE126730. The 16S rRNA gene data described in this study have been deposited in the Sequence Read Archive (SRA) at the NCBI (PRJNA525606).

## Supplemental material

**Additional file 1** Gene expression profiles (Microarray analysis) of colon and ileum. Only genes that were statistically significantly different ( $p < 0.05$ ) and had a fold change (FC)  $< -1.2$  or  $> 1.2$  between groups are included.

## CHAPTER 4

# The effects of sulfated secondary bile acids on intestinal barrier function and immune response in an inflammatory *in vitro* human intestinal model

## Abstract

Dysbiosis-related perturbations in bile acid (BA) metabolism were observed in inflammatory bowel disease (IBD) patients, which was characterized by increased levels of sulfated BAs at the expense of secondary BAs. However, the exact effects of sulfated BAs on the etiology of IBD are not investigated yet. Therefore, we aimed to investigate the effects of sulfated deoxycholic acid (DCA), sulfated lithocholic acid (LCA) and their unsulfated forms on intestinal barrier function and immune response. To this end, we first established a novel *in vitro* human intestinal model to mimic chronic intestinal inflammation as seen during IBD. This model consisted of a co-culture of Caco-2 and HT29-MTX-E12 cells grown on a semi-wet interface with mechanical stimulation to represent the mucus layer. A pro-inflammatory environment was created by combining the co-culture with LPS-activated dendritic cells (DCs) in the basolateral compartment. The presence of activated DCs caused a decrease in transepithelial electrical resistance (TEER), which was slightly restored by LCA and sulfated DCA. The expression of genes related to intestinal epithelial integrity and the mucus layer were slightly, but not significantly increased. These results imply that sulfated BAs have a minor effect on intestinal barrier function in Caco-2 and HT29-MTX-E12 cells. When exposed directly to DCs, our results point towards anti-inflammatory effects of secondary BAs, but not sulfated secondary BAs. These findings emphasize the importance of proper transformation of BAs by bacterial enzymes and the potential involvement of BA dysmetabolism in IBD progression.

## Introduction

Inflammatory bowel disease (IBD) comprises a set of disorders that causes chronic and relapsing inflammation of the gastrointestinal tract. The etiology of IBD remains largely unknown, although it is clear that it is a multifactorial disease, in which the complex interplay between genetic susceptibility, environmental stimuli and the immune system are involved (1, 2). Furthermore, the gut microbiota is thought to play a major role in the onset and progression of IBD, which is emphasized by studies showing that gut microbiota composition in IBD patients is dysbiotic (3-6). Dysbiosis is linked to disturbed intestinal barrier function, such as increased intestinal permeability (7) and an impaired mucus layer (8, 9). Impaired intestinal barrier function enables direct bacterial contact with the epithelial cell layer, thereby inducing an inflammatory response (10-13). In a healthy situation, the intestinal mucosal immune system is tolerant against commensal bacteria, a process in which intestinal dendritic cells (DCs) play a crucial role (14-16). During IBD, intestinal DCs have lost their tolerogenic function and produce elevated levels of pro-inflammatory cytokines, consequently leading to an exacerbated disease progression (17, 18).

Importantly, dysbiosis is also linked to an altered production of bacterial metabolites, such as secondary bile acids (BAs) (3, 19-21). Primary BAs are synthesized in the liver, conjugated with taurine or glycine and secreted in the small intestine, where they accomplish a major role in lipid digestion (22). BAs are actively reabsorbed in the ileum, transported back to the liver and metabolized by hepatic enzymes to be reused again, which is a process called the enterohepatic cycle (22). Approximately 5% of all BAs are not reabsorbed and enter the colon, where resident bacteria deconjugate and metabolize them into secondary BAs. These secondary BAs can be either excreted via feces or reabsorbed and transported back to the liver. However, secondary BAs might be hepatotoxic at high concentrations and are therefore first detoxified by addition of a sulfonate group ( $\text{SO}_3^-$ ) (23). As a result of IBD-related dysbiosis, the production of bacterial enzymes and thus BA metabolism can be disturbed, a process known as BA dysmetabolism (24). Indeed, the capacity of the gut microbiota to deconjugate BAs and transform primary to secondary BAs was decreased in patients with active IBD. As a consequence, increased abundance of conjugated BAs and decreased abundance of secondary BAs in feces of IBD patients during both remission and active disease was detected, as compared to healthy people (3, 25). Similar differences in BA composition were found in other studies investigating fecal metabolite pools in IBD patients (19, 20, 26, 27). Interestingly, dysbiosis in IBD patients was also associated with a reduced desulfation capacity, which was concomitant with 15% higher levels of fecal sulfated BAs (3). Likewise, increased levels of fecal 3-sulfodeoxycholic acid and chenodeoxycholic acid sulfate were found in Crohn's disease patients (20). The fecal abundance

of sulfated BAs was also found to be elevated in patients with non-inflammatory intestinal disorders, such as diarrhea-predominated irritable bowel syndrome (25, 28).

Given the important signaling functions of secondary BAs, including their role in inflammatory pathways, a change in luminal BA composition may have consequences on the progression of IBD. However, the possible involvement of sulfated BAs is only based on associative studies and the causal effects remain elusive. Therefore, the aim of this study was to investigate the effects of sulfated BAs on intestinal barrier function and immune response. Since existing models often insufficiently approach the physiological representation of the intestinal barrier and inflammatory environment in the context of IBD, we first established a novel inflammatory *in vitro* human intestinal model. We included a co-culture of Caco-2 and HT29-MTX-E12 cells, which are both human colon carcinoma cell lines representing an enterotype and a mucus-producing cell line, respectively. To mimic the inflammatory state as observed during IBD, the co-culture was grown on cell culture inserts in combination with DCs in the basolateral compartment, which were activated with LPS to obtain pro-inflammatory properties. In contrast to existing models, our model had an improved mucus layer by growing the cells on a semi-wet interface with mechanical stimulation (SMWS) (29, 30). After exposure to sulfated deoxycholic acid (DCA), sulfated lithocholic acid (LCA) and their unsulfated forms for 24 hours, the effects on intestinal barrier function and immune response were investigated. New insights into the role of BA dysmetabolism in IBD may contribute to the discovery of novel therapies that may add to the treatment of IBD.

## Materials and methods

### Cell culture

Caco-2 cells (ATCC) and HT29-MTX-E12 cells (ECACC) were cultured in Dulbecco's Modified Eagle Medium supplemented with 10% Fetal Bovine Serum and 1% penicillin/streptomycin. Cells were grown until 80-90% confluence at 37°C/5% CO<sub>2</sub>. Passage numbers between 7 and 25 were used for Caco-2 cells and between 3 and 15 for HT29-MTX-E12 cells. Monocytes were isolated from buffy coats originated from different blood donors (Sanquin, Nijmegen, The Netherlands). First, PBMCs were isolated from the buffy coat using LeucoSep tubes (Greiner-Bio One, Alphen aan den Rijn, The Netherlands), pre-filled with Ficoll-Paque Plus (GE Healthcare via Sigma-Aldrich). PBMCs were filtered through a 70 µm cell strainer (Corning) and counted using a Vi-Cell counter (Beckman Coulter, Woerden, The Netherlands). A QuadroMACS Separator (Miltenyi Biotec, Leiden, The Netherlands)

was used to magnetically separate CD14<sup>+</sup> monocytes, using MojoSort Human CD14 Nanobeads (BioLegend, London, UK) diluted in MACS buffer (PBS, 0.5% BSA and 2mM EDTA) following the manufacturer's instructions. Monocytes were resuspended in RPMI, supplemented with 10% FCS, 1% penicillin/streptomycin and 1% GlutaMAX (Gibco). Monocytes were differentiated into dendritic cells by adding 10 ng/mL Granulocyte macrophage-colony stimulating factor (GM-CSF) (Miltenyi Biotec, Leiden, The Netherlands) and 10 ng/mL human recombinant IL-4 (PeproTech, London, UK) for 6 days at 37°C/5% CO<sub>2</sub>.

### Cell model

A co-culture of Caco-2 cells and HT29-MTX-E12 cells was seeded in 24-well ThinCert cell culture inserts with 0.4 µm pores (Greiner-Bio One, Alphen aan den Rijn, The Netherlands). Caco-2 and HT29-MTX-E12 cells were seeded in a 3:1 ratio, using a seeding density of 225,000 cells/mL in a volume of 150 µL. A volume of 700 µL DMEM was added to the basolateral compartment. Two days after seeding, media volumes were changed to 25 µL and 425 µL in the apical and basolateral compartment, respectively. The cell culture plates were put on a CO<sub>2</sub> resistant shaker (Thermo Fisher Scientific, Breda, The Netherlands) at 65 rpm. Cells were differentiated for 14 days and medium was changed every other day. Immature DCs were seeded in 24-wells plates in a density of 400,000 cells per well. DCs were stimulated with 10 ng/mL LPS (L3024, Sigma-Aldrich, Darmstadt, Germany) for 24 hours. Maturation of DCs was checked on the CytoFLEX Flow Cytometer (Beckman Coulter, Woerden, The Netherlands) using CD14-ECD antibody, clone RMO52 (IM2707U, Beckman Coulter), FITC anti-human CD83, clone HB15e and PE/Cyanine7 anti-human CD209 (DC-SIGN), clone 9E9A8 antibodies (BioLegend, Amsterdam, The Netherlands). The culture inserts with Caco-2 and HT29-MTX-E12 cells were transferred to the cell culture plate containing the LPS-activated DCs. The co-culture was exposed to lithocholic acid 3-sulfate disodium salt (sulfo-LCA) (Santa-Cruz Biotechnology, Dallas, United States), deoxycholic acid 3-O-sulfate disodium salt (sulfo-DCA) (Toronto Research Chemicals, Toronto, Canada), lithocholic acid (LCA) and deoxycholic acid (DCA) (Sigma-Aldrich, Darmstadt, Germany). LCA and sulfo-LCA were solubilized in DMEM:methanol (1:1, v/v). DCA and sulfo-DCA were solubilized in DMEM:methanol (3:1, v/v). A control without DCs and a control with LPS-activated DCs were included. Control cells were exposed to similar concentrations of methanol (0.5%). Every condition was applied in duplicate. A total of three similar plates were seeded and exposed to BAs; plate 1 was used for permeability assays, plate 2 for RNA isolation and plate 3 three for protein isolation. Experiments where DCs were directly exposed to BAs were performed similarly, except that BAs were applied directly to the DCs.

**Quantification of lactate hydrogenase release**

To investigate the effects of BA exposure on cytotoxicity of Caco-2 and HT29-MTX-E12 cells and DCs, lactate hydrogenase levels were measured in conditioned medium collected directly after 24 hours of BA exposure. To this end, a lactate dehydrogenase (LDH) cytotoxicity detection kit (Roche Applied Science; Almere, The Netherlands) was used following the manufacturer's instructions. As a control for complete cytotoxicity, cells were exposed for 15 minutes to a 1% Triton-X100 solution.

**Trans- and paracellular epithelial permeability assays**

Transepithelial resistance (TEER) was measured with an EVOM2 Volt/Ohm meter using STX2 electrodes (World Precision Instruments, Sarasota, United States). To assure the electrodes were fully submerged in medium, the media volumes were adapted to 100  $\mu$ L apical and 700  $\mu$ L basolateral before the first TEER measurements were performed. The TEER values after BA exposure were expressed as percentage of the TEER value measured just before BA exposure. After 24 hours of BA exposure, culture inserts were washed twice with PBS and transferred to a new 24-wells plate. Lucifer Yellow CH dilithium salt (L0259, Sigma) was dissolved in phenol red-free medium (Gibco) to 1 mg/mL and 100  $\mu$ L was added to the apical compartment. In the basolateral compartment, 700  $\mu$ L phenol red-free DMEM was added and afterwards the plate was incubated at 37°C/5% CO<sub>2</sub> for 3 hours. Subsequently, 100  $\mu$ L of the basolateral compartment was collected and fluorescence was measured at 425/515 nm (excitation/emission). An empty cell culture insert served as a control for complete paracellular permeability.

**RNA isolation and qRT-PCR**

The cell culture inserts of plate 2 were washed twice with ice-cold PBS and subsequently, 200  $\mu$ L TRIzol reagent (ThermoFisher) was added per insert. The duplicates per condition were pooled to assure enough RNA yield. RNA was isolated using phenol/chloroform extraction. The RNA concentration was measured using a Nanodrop (Nanodrop ND-1000, Nanodrop Products, Maarssen, The Netherlands). A total of 1000 ng RNA was reverse transcribed using the RevertAid First Strand cDNA Synthesis kit (ThermoFisher). Real-time quantitative PCR was carried out using the SensiMix SYBR kit (Bioline, Alphen aan den Rijn, The Netherlands) in a CFX384 machine (Bio-Rad). Primer sequences are listed in Table 1. Data was normalized against the housekeeping gene *GAPDH*.

### Protein isolation and Western Immunoblotting

The cell culture inserts were washed twice with ice-cold PBS and 100  $\mu$ L RIPA buffer (ThermoFisher) enriched with protease- and phosphatase inhibitors (Roche Diagnostics) was added per culture insert. Duplicates were pooled to assure enough protein yield. Cell lysates were incubated on ice for 20 minutes following centrifugation for 10 minutes at 13,000 *g*. Protein concentrations of the supernatants were measured using a bicinchoninic acid assay (ThermoFisher). For each sample, 14.8  $\mu$ g protein was loaded on a 4-15% Mini-PROTEAN TGX Precast gel (Bio-Rad). Proteins were separated by SDS gel electrophoresis and transferred onto a polyvinylidene difluoride (Trans-Blot Turbo Midi 0.2  $\mu$ m PVDF Transfer Packs, Bio-Rad) membrane using the Transblot Turbo System (Bio-Rad). After blocking for 1 hour at room temperature, the membranes were incubated overnight at 4°C with anti-ZO1 (Abcam ab216880), anti-OCN (Abcam ab216327) and anti-HSP90 (Cell Signaling Technology 4874). ZO1 and OCN antibodies were used in 1:1000 and for HSP90 1:5000 was used. Subsequently, membranes were incubated with HRP conjugated goat anti-rabbit IgG antibody (1:5000) (GenScript A00098) for 1 hour at room temperature. All membrane incubations were in Tris-buffered saline with 0.1% Tween 20 (TBS-T) and 5% (w/v) skimmed dry milk. Washing in between

steps was done in TBS-T. Blots were visualized with Clarity ECL substrate (Bio-Rad) using the ChemiDoc MP system (Bio-Rad). Quantification was performed using ImageLab software (Bio-Rad).

### Cytokine measurements

Medium collected from the basolateral compartments was used for the assessment of cytokines. Levels of IL-6, IL-12/IL-23 p40 and TNF- $\alpha$  were measured with human DuoSet ELISA Development kits (R&D Systems, Abingdon, UK) following the manufacturer's instructions.

### Statistical analysis

Data is presented as mean  $\pm$  standard error of mean (SEM). GraphPad Prism version 5 (San Diego, CA, USA) was used for the statistical analyses. Differences between the control and BA-exposed groups were determined with an unpaired Student's t-test, unless stated otherwise. A value of  $p \leq 0.05$  was considered as statistically significant. A total of three biological replicates were performed.

## Results

### Establishment of an inflammatory *in vitro* human intestinal model consisting of Caco-2 and HT29-MTX-E12 cells combined with LPS-activated dendritic cells

The first important step of this study was to establish an *in vitro* human intestinal model with an improved physiological representation of the intestinal barrier and inflammatory environment in the context of IBD. In **Figure 1A**, a schematic overview of the study design is given. Caco-2 and HT29-MTX-E12 cells were seeded in a 3:1 ratio on cell culture inserts and SWMS conditions were applied. In parallel, primary monocytes were isolated from three human buffy coats and differentiated into DCs. Activation with 10 ng/mL LPS for 24 hours resulted in mature DCs expressing the DC surface markers CD83 and CD209 (**Supplementary file 1**). Activated DCs produced higher levels of IL-6 ( $p = 0.0088$ ) and IL-12p40 ( $p = 0.1$ ) compared to DCs that were not activated (**Fig. 1B, C**), although IL-12p40 levels of one biological replicate were relatively low (**Fig. 1C**). After 24 hours of LPS exposure, the cell culture inserts with the Caco-2/HT29-MTX-E12 co-culture were positioned in the cell culture plates containing activated DCs. This resulted in a model consisting of intestinal cells in the apical compartment and LPS-activated DCs in the basolateral compartment (**Fig. 1D**). TEER values measured at 24 and 48 hours after combination with activated DCs decreased with 12 and 45 percentage points, respectively, compared to the condition without basolateral DCs ( $p < 0.001$  and

$p < 0.0001$ ) (**Fig. 1E**). In the next BA-exposure experiments, we used a pre-incubation period of 24 hours. Altogether, we confirmed that the presence of activated DCs in the basolateral compartment caused a pro-inflammatory state, reflected by the elevated cytokine levels. This likely resulted in the observed increased intestinal permeability of the intestinal cells.

Schematic overview of the Caco-2 and HT29-MTX-E12 co-culture grown in a 3:1 ratio on cell culture inserts with a the mucus layer on top and activated DCs in basolateral compartment. **(E)** TEER measurements of Caco-2 and HT29-MTX-E12 culture at 24 and 48 hours. TEER values are expressed as percentage of the initial value. First bar pair: control cells without DCs, second bar pair: control cells with 10 ng/mL LPS in the basolateral compartment, third bar pair: cells combined with activated DCs. Statistical differences were determined using a one-way analysis of variance (ANOVA) followed by a Bonferroni post hoc test. ap < 0.001 at T=24h compared to condition with activated DCs. bp < 0.001 at T=48h compared to condition without DCs, but with basolateral LPS. cp < 0.0001 at T=48h compared to condition with activated DCs. dp < 0.05 at T=48h compared to condition with activated DCs. \*\*\*\*p < 0.0001. Data are derived from 3 independent biological replicates.

### Intestinal permeability was slightly restored by LCA and sulfated DCA under inflammatory conditions

After the pre-incubation period, the co-cultures of Caco-2 and HT29-MTX-E12 cells were exposed to sulfated DCA, sulfated LCA and their unsulfated forms in different concentrations for another 24 hours. Cytotoxicity measured by the release of LDH in the apical medium was not different between cells exposed to BAs compared to unexposed cells (data not shown). The TEER of all conditions exposed to BAs in the presence of activated DCs were significantly lower compared to the control without DCs ( $p < 0.0001$ ) (**Fig. 2A**). Exposure to sulfated DCA (200  $\mu$ M) and both concentrations of LCA (10  $\mu$ M and 50  $\mu$ M) resulted in a slight, but significant restoration of the TEER (**Fig. 2A**). The same cell culture inserts were subjected to a Lucifer Yellow assay to investigate if BA treatment had an effect on paracellular permeability. The flux of Lucifer Yellow from the apical to basolateral compartment was significantly lower in cells cultured without DCs compared to the control with DCs ( $p < 0.05$ ) (**Fig. 2B**). None of the BAs had a significant additional effect on paracellular permeability.

**Figure 2** Intestinal permeability assays of Caco-2 and HT29-MTX-E12 cells combined with activated DCs after treatment with (sulfated) BAs for 24h. (A) TEER values expressed as % of initial values. (B) Fluorescence measured in basolateral compartment after 3h apical Lucifer Yellow incubation, expressed as % of an empty cell culture insert (representing complete translocation). (C-D) Protein quantity of OCLN and ZO1 relative to the control. (E-H) Panel of genes related to intestinal permeability (*OCLN*: Occludin, *ZO1*: Zonula Occludens-1, *CDH1*: E-cadherin, *CLDN1*: Claudin-1). Expression of proteins and genes of interest is expressed relative to the control (Caco-2 and HT29-MTX-E12 cells exposed to activated DCs in basolateral compartment). \* $p < 0.05$ ; \*\* $p < 0.01$ ; \*\*\*\* $p < 0.0001$  compared to the control condition with activated DCs.

### Expression of genes related to intestinal epithelial integrity tended to increase after BA exposure

To further investigate the effects of sulfated secondary BAs on intestinal barrier function, we measured the expression of proteins related to intestinal epithelial integrity. In line with the significant TEER reduction (**Fig. 2A**), lower protein levels of Occludin (OCLN) and Zonula Occludens-1 (ZO1) were measured in cells exposed to activated DCs compared to the control cells without DCs (**Fig. 2C-D**), but these differences were not significant. Next, we investigated whether these lower protein levels were the result of decreased mRNA levels. However, *OCLN* and *ZO1* mRNA levels were not significantly affected by the presence of activated DCs in the basolateral compartment (**Fig. 2E-F**). Other genes related to intestinal barrier function, E-cadherin (*CDH1*) and Claudin-1 (*CLDN1*), were also not affected (**Fig. 2G-H**). Interestingly, protein levels of OCLN and ZO1 were not affected by BA exposure, whereas expression of *OCLN*, *ZO1*, *CDH1* and *CLDN1* followed an increasing trend after exposure to most BAs, although these differences were not significant (**Fig. 2C-H**). Together, these results indicate that differences in intestinal barrier function measured by TEER were partly reflected at gene and protein level.

### Differential expression of FXR-target genes by unsulfated, but not sulfated secondary BAs

Next, we aimed to find out if exposure to sulfated and unsulfated secondary BAs resulted in activation of FXR. While DCA and LCA are potent activators of FXR (22), it is unknown whether the sulfated forms of these BAs also activate FXR, as these BAs are not, or poorly absorbed by enterocytes (23). To this end, we investigated if exposure to DCA, LCA and their sulfated forms resulted in differential expression of a selection of FXR-target genes: ileal bile acid binding protein (*IBABP*, *FABP6*), fibroblast growth factor 19 (*FGF19*), basolateral organic solute transporters alpha and beta (*OSTα/β*, *SLC51A/B*), apical bile salt transporter (*ABST*, *SLC10A2*) and sulfotransferase family 2A member 1 (*SULT2A1*) (31-34). Interestingly, the addition of activated DCs potentially reduced the expression of *ABST* ( $p < 0.05$ ) and *SULT2A1* ( $p < 0.001$ ) (**Fig. 3A, F**). *ABST* was not differentially expressed by any of the BAs (**Fig. 3A**). In contrast, *FABP6*, *FGF19* and *OSTβ* were significantly upregulated in cells exposed to DCA compared to the control with activated DCs (**Fig. 3B-C, E**). Interestingly, exposure to 100 μM DCA reduced *SULT2A1* expression compared to the control cells with DCs (**Fig. 3F**). Altogether, these results indicate that DCA had pronounced effects on the expression of most FXR-target genes, while LCA had only minor effects. Exposure to neither sulfated DCA nor sulfated LCA resulted in a differential expression of any FXR-target genes. Importantly, mRNA levels of *ABST* and *SULT2A1* were significantly decreased by the presence of basolateral activated DCs.

**Figure 3 Expression of FXR target genes (A-F)** *ABST*, *FABP6*, *FGF19*, *OSTα*, *OSTβ* and *SULT2A1*. Expression of genes of interest is expressed as fold change relative to control (Caco-2 and HT29-MTX-E12 cells exposed to activated DCs in basolateral compartment). \* $p < 0.05$ , \*\* $p < 0.01$ , \*\*\* $p < 0.001$  compared to the condition with activated DCs.

#### No effects of sulfated secondary BAs on *MUC2* and *MUC5AC* expression

In order to determine if sulfated secondary BAs had an effect on the mucus layer, we investigated the expression of *MUC2*, which is the most dominant gel-forming mucin present in the intestine. Moreover, we also measured expression of *MUC5AC*. This is another gel-forming mucin which is normally not secreted in the intestine, but is secreted in HT29-MTX-E12 cells, even after growing this cell type under SWMS conditions (29, 30). Interestingly, the presence of activated DCs decreased the expression of *MUC2* and *MUC5AC*, although this effect was not statistically significant (**Fig. 4A-**

**B).** Compared to the control with activated DCs, the expression of *MUC2* seemed to increase after exposure to 100  $\mu\text{M}$  DCA and 10  $\mu\text{M}$  LCA, which was borderline significant ( $p = 0.06$  and  $p = 0.08$ ), respectively (**Fig. 4A**). Sulfated BA exposure did not have any effect on mucin mRNA expression.

**Subtle effect of some BAs on expression of genes encoding for antimicrobial peptides**

Antimicrobial peptides (AMPs) play an important role in intestinal innate immune defense and are known to be produced by enterocytes (35). We measured the expression of genes encoding the AMPs defensin  $\beta$ -1 (*DEFB1*) and lysozyme (*LYZ*), but also angiogenin (*ANG*) and carbonic anhydrase 12 (*CA12*), since the latter two AMPs are regulated by the BA receptor FXR (36, 37). Exposure to BAs caused slight, but non-significant changes compared to the control with activated DCs (**Fig. 4C-F**). Only *ANG* was significantly lower expressed after exposure to both 100  $\mu\text{M}$  sulfated DCA and DCA, as well as 50  $\mu\text{M}$  LCA ( $p < 0.05$ ) (**Fig. 4F**).

**Figure 4 Expression of mucin and antimicrobial peptides. A)** Expression of MUC2 and **B)** MUC5AC and genes encoding the antimicrobial peptides **(C-F)** DEFB1, LYZ, CA12 and ANG. Expression of genes of interest is expressed relative to the control (Caco-2 and HT29-MTX-E12 cells exposed to activated DCs in basolateral compartment). \* $p < 0.05$  compared to condition with activated DCs.

#### No indirect effects of BA exposure on cytokine production by basolateral DCs

Although the presence of activated DCs in the basolateral compartment resulted in a significant increase in permeability of the Caco-2/HT29-MTX-E12 co-culture, apical exposure to sulfated and unsulfated secondary BAs did not have a major additional effect on intestinal epithelial integrity (**Fig. 2A-B**). We hypothesized that BAs might have migrated from the apical to the basolateral compartment via the openings between the intestinal epithelial cells, caused by the increased intestinal permeability. In that case, BAs might have come in contact with the DCs present in the basolateral compartment. Therefore, we investigated if this potential indirect contact between BAs and DCs caused an altered immune response by DCs. To this end, TNF- $\alpha$  and IL-12p40 levels were measured in conditioned medium from basolateral DCs after apical exposure to the different BAs. No differences in either TNF- $\alpha$  or IL-12p40 levels were found (**Fig. 5A-B**).

**Figure 5 Cytokine levels produced by basolateral DCs after indirect BA exposure (via cell culture inserts) and direct exposure. A)** TNF- $\alpha$  and **B)** IL-12p40 levels after indirect exposure. **C)** TNF- $\alpha$  and **D)**

IL-12p40 levels after direct exposure. Cytokine levels are expressed as percentage of the control, i.e. DCs exposed to only medium.

---

#### **Decreasing, but no significant trend in TNF- $\alpha$ and IL-12p40 production by activated DCs after direct exposure to secondary BAs**

The finding that cytokine production by DCs was not affected by indirect BA exposure could either indicate that BAs were not migrated towards the basolateral compartment, or that DCs were not affected by BA exposure in terms of TNF- $\alpha$  and IL-12p40 production. To investigate if direct exposure to BAs caused an effect on immune response in DCs, we exposed activated DCs directly to sulfated and unsulfated secondary BAs under similar conditions as previous experiments with indirect exposure. DCA caused a decrease in both TNF- $\alpha$  and IL-12p40 levels compared to the control cells (**Fig. 5C-D**), but these differences were not significant. Lower IL-12p40 levels were found after LCA exposure, albeit variation between biological replicates was high (**Fig. 5D**). This was due to deviating results from one biological replicate (**Supplementary file 1**). No significant differences were found after exposure to sulfated BAs.

### **Discussion**

The rising prevalence of IBD in many countries is alarming, given the concomitant increase in social and economic burden associated with this disease (38). To decrease this burden, it is of utmost importance to better understand the underlying causes of IBD, especially because the etiology of IBD is still largely unknown. Emerging evidence suggests a potential role for BA dysmetabolism in IBD, however, the exact effects of elevated levels of IBD-associated BA subtypes are not widely investigated yet. In the present study, we aimed to investigate the effects of sulfated secondary BAs on intestinal barrier function in the context of IBD. Furthermore, we also investigated if sulfated BAs had an effect on immune response in human monocyte-derived DCs.

We first aimed to establish an inflammatory *in vitro* human intestinal model, as existing models often insufficiently reflect the chronic inflammatory state in the context of IBD. For example, many existing models either add a cytokine cocktail to induce a pro-inflammatory state (39, 40) or use THP-1 cells as representation of immune cells (41-46). The effectiveness of this cell line in an intestinal model is questionable. In two studies, Caco-2 cells exposed to THP-1 cells were severely damaged after 48 hours, which was reflected by the high cytotoxicity values and TEER decrease of more than 80% (44, 46). Given the crucial role of intestinal DCs in IBD pathophysiology (14, 47), we used

human monocyte-derived DCs in our model. After activation with LPS, these DCs produced high cytokine levels, resulting in an increased intestinal permeability without affecting cytotoxicity. To improve the physiological representativeness of our model even more, we also paid special attention to the mucus layer, since it is often underrepresented or even lacking in most existing intestinal *in vitro* models. Therefore, we cultured the Caco-2/HT29-MTX-E12 co-culture under SWMS conditions, which was shown to improve the quantity and quality of the mucus layer (29, 30).

After successful optimization, we exposed the inflammatory *in vitro* human intestinal immune model to sulfated and unsulfated secondary BAs for 24 hours and investigated the effects on intestinal barrier function. We found a slight TEER restoration after exposure to LCA and sulfated DCA, but not DCA and sulfated LCA. These effects on intestinal epithelial barrier integrity were partly reflected at protein level. Previous *in vitro* studies also showed TEER restoration by LCA in the presence of inflammatory conditions (40, 48). With regard to DCA, we did not find an effect on TEER, while a marked increased permeability caused by DCA was observed in several *in vitro* models (49–52) as well as in mice (51, 53, 54). Importantly, we confirmed successful administration of DCA and LCA by measuring differential expression of FXR-target genes. Differences in incubation duration and BA concentrations might have impeded direct comparison to existing literature and results of the current study.

In line with the minor effects on intestinal epithelial barrier integrity, we did not find an effect of sulfated BAs on *MUC2* and *MUC5AC* expression. On the contrary, DCA and LCA exposure resulted in an increased expression of *MUC2*, which was borderline significant. As *MUC2* plays a crucial role in intestinal barrier protection (55–58), increased *MUC2* mRNA expression might indicate that these BAs have a restorative effect on the mucus layer. In several human colon cancer cell lines, DCA also caused increased *MUC2* expression (59, 60), but no effects of LCA on mucin mRNA expression have been described. Importantly, it was previously shown that prolonged exposure to pro-inflammatory cytokines strongly decreased mucin gene expression (61, 62). These results are in line with the decreasing trend in *MUC2* and *MUC5AC* expression that we found after exposure to activated DCs, although this effect was not significant. Next to the effects of BAs on the mucus barrier, it is also important to consider other intestinal barrier properties, such as AMPs that are excreted in the mucus layer (63). Although DCA was previously shown to increase the expression and secretion of *DEFB1/DEFB1* *in vitro* (64), we were not able to reproduce these results. We did find a slightly reduced expression of *ANG* by some BAs, which might imply that these BAs have a negative effect on mucosal defense (65). However, the effects of BAs on AMPs are underexplored in current literature, indicating that more research is needed in this field.

Secondary BAs could have anti-inflammatory effects during intestinal inflammation (27, 66, 67). Since intestinal DCs are able to sample luminal content (47, 68), we hypothesized that luminal BAs could come in contact with DCs, which might result in an altered immune response. Indeed, direct exposure to secondary BAs caused a decreasing trend in cytokine production, but this effect was absent after exposure to sulfated secondary BAs. This finding might suggest that increased levels of sulfated BAs at the expense of secondary BAs could abolish the anti-inflammatory effects of secondary BAs. Similar effects were previously found in Caco-2 exposed to sulfated LCA (3), although this effect was found after exposure to relatively high concentrations of LCA and sulfated LCA (400 and 500  $\mu\text{M}$ ), which might hamper the physiological translatability of these results.

Here, we present a novel and physiological relevant *in vitro* human intestinal model representing a pro-inflammatory state, which can be used to study intestinal barrier function in the presence of intestinal inflammation. We used this model to investigate the effects of sulfated and unsulfated secondary BAs on intestinal barrier function and immune response in DCs. We show that these BAs had ambiguous effects on intestinal barrier integrity, as reflected by the minor effects on TEER, expression of intestinal epithelial integrity related genes, AMPs and *MUC2*. Our results hint towards anti-inflammatory effects of secondary BAs, but not sulfated secondary BAs on activated DCs. These findings emphasize the potential impact of BA dysmetabolism during IBD and the relevance of proper bacterial desulfation activity to assure the anti-inflammatory effects of secondary BAs.

## Abstract

The intestinal mucus layer plays a crucial role in human health. To study intestinal mucus function and structure in vitro, the mucus-producing intestinal cell line HT29-MTX-E12 has been commonly used. However, this cell line produces only low amounts of the intestine-specific MUC2. It has been shown previously that HT29-MTX-E12 cells cultured under Semi-Wet interface with Mechanical Stimulation (SWMS) produced higher amounts of MUC2, concomitant with a thicker mucus layer, compared to cells cultured conventionally. However, it remains unknown which underlying pathways are involved. Therefore, we aimed to further explore the cellular processes underlying the increased mucus production by HT29-MTX-E12 cells grown under SWMS conditions. Cells grown on Transwell membranes for 14 days under static and SWMS conditions (after cell seeding and attachment) were subjected to transcriptome analysis to investigate underlying molecular pathways at gene expression level. Caco-2 and LS174T cell lines were included as references. We characterized how SWMS conditions affected HT29-MTX-E12 cells in terms of epithelial barrier integrity, by measuring transepithelial electrical resistance, and cell metabolism, by monitoring pH and lactate production per molecule glucose of the conditioned medium. We confirmed higher MUC2 production under SWMS conditions at gene and protein level and demonstrated that this culturing method primarily stimulated cell growth. In addition, we also found evidence for a more aerobic cell metabolism under SWMS, as shown previously for similar models. In summary, we suggest different mechanisms by which mucus production is enhanced under SWMS and propose potential applications of this model in future studies.

## Introduction

The surface of the human gastro-intestinal (GI) tract is covered by a layer of mucus, protecting the host from pathogens, harmful chemical or biological substances and physical damage (1-4). Defects in this mucus layer have been implicated in several intestinal pathologies. For instance, *Muc2* knock-out mice were shown to develop spontaneous colitis (5) and colorectal cancer (6), emphasizing the important protective role of mucus. Along the GI tract, the mucus layer is thickest in the colon (7), where the number of intestinal bacteria is also highest (8). Interestingly, the mucus layer does not only protect the underlying epithelium from these high bacterial numbers, but also provides a binding site and nutrition-rich niche for residing intestinal bacteria, such as mucin-degrading bacterial species and cross-feeders which in concert produce beneficial compounds (e.g. short-chain fatty acids) for the host (9, 10).

The dual role of colonic mucus can be explained by the existence of two layers: The inner layer is densely packed, firmly attached to the intestinal epithelium and devoid of bacteria, whereas the outer layer is loose, constantly removed and colonized by bacteria (7, 11). Colonic mucus is mainly composed of the gel-forming mucin type 2 (MUC2) (12, 13), a heavily O-glycosylated protein secreted by intestinal goblet cells (14-16). Additionally, mucus contains salts, lipids (17) and defense-related proteins, such as antimicrobial peptides, growth factors, trefoil factors, immunoglobulins, lysozyme and other proteins (11).

Our understanding of colonic mucus structure, function and composition has been largely dependent on *in vivo* models, such as rodents and pigs (reviewed in Etienne-Mesmin *et al.* (18)) or *ex vivo* techniques using human mucosal biopsies (first established by Browning *et al.* (19)) and murine intestinal explants (20, 21). These models, however, show large heterogeneity between and within subjects or, in the case of animal models, have a poor translational value. Additionally, these models are often expensive, require specialized experience and pose ethical concerns. Attempts have been made to recapitulate the intestinal mucosal layer – including host cells – *in vitro*, varying from simple to more advanced systems. Relatively simple cell models include the use of mucus-excreting colonic cancer cell lines, such as HT29-MTX and LS174T cells (22, 23), but both examples have limitations. HT29-MTX cells have successfully been grown in confluent monolayers (24), but this cell type predominantly secretes MUC5AC, a mucin that is present in the stomach and airways, while producing only a limited amount of colon-specific MUC2 (22). On the other hand, LS174T cells do produce MUC2 (23), but are not capable of growing in an organized and adherent cell layer (25). More advanced models include culturing cell lines in innovative models, such as gut-on-chips (26, 27) or 3D scaffolds (28-30); or the use of human colonoids (31, 32) and human intestinal organoids

(33); or a combination (34), which all demonstrated increased MUC2 production *in vitro* compared to conventional cell culture. Although these models are supposed to resemble the *in vivo* colonic mucosal layer more closely in terms of mucus composition, they are highly expensive and require specialized expertise (18).

To obtain more physiologically relevant models, simpler yet effective alternative strategies have been shown to further increase mucus production in intestinal cancer cell lines, using biochemical compounds, such as prostaglandin E2 (35) and Notch  $\gamma$ -secretase inhibitors (36), or bacteria-derived compounds (e.g. sodium butyrate (37) and LPS (38)). Physical strategies have also been applied, e.g. growing intestinal porcine epithelial cells at an air-liquid interface (ALI) (39, 40), stimulating cells mechanically, or a combination of both. For instance, Navabi and colleagues managed to create polarized, functional, crypt-forming intestinal cell layers with an adherent mucus layer, when growing HT29-MTX-E12 and other intestinal cell lines on Transwell membranes in semi-wet interfaces with mechanical stimulation (SWMS). SWMS conditions include decreased apical and basolateral medium volumes and continuous shaking on a rocking platform. Importantly, these cells demonstrated increased expression of MUC2, both absolute and relative to MUC5AC (25). HT29-MTX-E12 cells grown under these conditions produced a thicker layer compared to static conditions. However, it remains unexplored what molecular mechanisms are involved.

In our study, we aimed to further explore the cellular processes underlying the increased mucus production by HT29-MTX-E12 cells grown under SWMS conditions. To this end, cells were subjected to transcriptome analysis after 15 days of culture to investigate underlying molecular pathways involved. As control cell lines for the transcriptomic analysis, we included Caco-2 and LS174T cells, a non-mucus producing and MUC2-producing cell line, respectively. Next, we further characterized the HT29-MTX-E12 monolayer, by measuring transepithelial electrical resistance and quantifying cell density. Additionally, as similar (semi-wet only) models have shown a more aerobic cell metabolism (41-44), we quantified pH and lactate production per molecule glucose of the conditioned medium. In overall, we attempted to gain more insight into the potential mechanisms underlying increased mucus production in HT29-MTX-E12 cells grown under SWMS conditions.

## Materials and Methods

### Cell culture

HT29-MTX-E12 cells (ECACC) were obtained from Sigma-Aldrich (Darmstadt, Germany). Caco-

2 (ATCC HTB-37) and LS174T (ATCC CL-188) cells were purchased at LGC Standards (Wesel, Germany). All cell types were cultured in Dulbecco's Modified Eagle Medium with 4.5g/L glucose, 110 mg/L sodium pyruvate and 584 mg/L L-glutamine (Corning, NY, USA) supplemented with 10% Fetal Bovine Serum and 1% penicillin/streptomycin. When cells reached 80-90% confluency, they were counted and seeded. Passage numbers between 15 and 27 were used for Caco-2 cells and between 3 and 21 for HT29-MTX-E12 cells. LS174T cells were used between passage 17 and 19. Caco-2 and HT29MTX-E21 cells were seeded (day 0) at a density of 273,000 cells/mL in 275  $\mu$ L per well on 12 mm 0.4  $\mu$ m-pore polyester Transwell membranes (Corning 3460). A volume of 1 mL medium was added to the basolateral compartment. One day after seeding (day 1), media of all Transwells was refreshed and Semi-Wet conditions with Mechanical Stimulation (SWMS) were applied (25, 30). To these Transwells, 75  $\mu$ L and 850  $\mu$ L of medium was added to the apical and basolateral compartments, respectively, and plates were put on a CO<sub>2</sub>-resistant shaker (Thermo Fisher Scientific, Breda, The Netherlands) at 65 rpm. Media volumes of Transwells grown under static conditions were unchanged. LS174T cells were seeded at similar seeding density on regular 12-well cell culture plates. This cell line was cultured under static conditions in a regular wells plate only, since these cells do not form a continuous monolayer of cells, but grow in a rather irregular manner (25). Medium was refreshed every Monday, Wednesday and Friday and cells were harvested 15 days after seeding ( $t = 15$  days).

### RNA isolation

Cells were washed with ice-cold PBS twice, trypsinized and RNA was isolated using the Maxwell®16 LEV simplyRNA Cells Kit (Promega, cat. no. AS1270) and the Maxwell® 16 MDx Instrument (Promega), following the manufacturer's instructions.

### Microarray

RNA isolate from three independent biological replicate experiments was used for microarray analysis. Total RNA yield was measured using photometry (DeNovix, USA). RNA quality was determined on an Agilent 2100 Bioanalyzer (Agilent Technologies, Amsterdam, The Netherlands). RNA was only used when the RNA integrity number (RIN) exceeded 8.0. One hundred nanogram of RNA was converted to cDNA and labelled (Ambion WT expression kit, Life Technologies, Bleiswijk, The Netherlands). Samples were hybridized to an Affymetrix Human Gene 1.1 ST array plate according to the standard Affymetrix instructions (Affymetrix, Santa Clara, CA, USA). The robust multi-array average (RMA) pre-processing algorithm in the Bioconductor library AffyPLM was used

to obtain normalized expression estimates (45). Probe sets were defined and assigned as described by Dai *et al.* (46). Differences in gene expression between static and SWMS conditions per cell type were analyzed using the Intensity Based Moderated T statistics (IBMT) (47), using  $p$  values  $<0.05$  as threshold. The Venn diagram was created using Venny 2.1 (48). Microarray data has been submitted to the Gene Expression Omnibus (GEO) at the NCBI (GSE173729).

### TEER measurements

The transepithelial electrical resistance (TEER) was measured with an EVOM2 Volt/Ohm meter using STX2 electrodes (World Precision Instruments) at day 4, 7, 9, 11 and 14. One hour prior to measuring, medium of the Transwells was refreshed and equal medium volumes were applied in all wells (275  $\mu$ L apical and 1 mL basolateral). Before TEER measurements were performed, Transwells were put at room temperature for 5 minutes to allow temperature equilibration. After TEER measurements, the medium volumes in the wells were adapted again to volumes of the respective conditions. The background value (i.e. TEER value of an empty Transwell) was subtracted from the total TEER values.

### Protein isolation

Cells were washed twice with PBS and lysed in RIPA Lysis and Extraction Buffer (ThermoFisher Scientific), supplemented with the protease and phosphatase inhibitors PhosSTOP and cOMplete (Roche Diagnostics, Almere, The Netherlands). Lysates were incubated on ice for 20 minutes following centrifugation for 10 minutes at 13,000  $\times g$ . Supernatant was collected and protein concentrations were measured using a bicinchoninic acid assay (Thermo Fisher Scientific).

### Western Blot

Protein lysates (20  $\mu$ g of protein/lane) were loaded onto 4-15% Mini-PROTEAN TGX Precast Protein Gels (Bio-Rad, Veenendaal, The Netherlands). Next, proteins were transferred onto a polyvinylidene difluoride membrane (Trans-Blot Turbo Midi 0.2  $\mu$ m PVDF Transfer Packs, Bio-Rad) using the Transblot Turbo System (Bio-Rad). Membranes were blocked for 1 hour and incubated overnight at 4 °C with rabbit anti-KLF4 (Sigma-Aldrich, catalogue no. SAB1300678) and rabbit anti-HSP90 (Cell Signaling Technology, cat. no. 4874). Antibodies were used in 1:500 and 1:5000 dilutions for KLF4 and HSP90, respectively. Membranes were incubated for 1 hour with goat anti-rabbit (GenScript, cat. no. A00098) diluted 1:5000. Blocking and incubation of primary and secondary antibodies were done in TBS with 0.1% Tween 20 (TBS-T) and 5% (w/v) skimmed milk. In between, membranes were washed in TBS-T. Signals were quantified using the ChemiDoc MP system (Bio-Rad) and Clarity ECL

substrate (Bio-Rad).

### Dot Blot

Proteins were diluted to 68.2 µg/mL and 6x serially diluted 1:2 in PBS. In total 7 dilutions and one PBS-control were blotted per condition. Of each dilution, 50 µL of sample was blotted on a Pierce 0.2 µm nitrocellulose membrane (Thermo Scientific) in a Dot Blot device (The Convertible, cat. series 1055. Gibco BRL) connected to a vacuum-pump. Next, membranes were blocked, incubated and imaged as described for Western Blot. Primary antibodies were diluted 1:2000 and 1:1000 for mouse anti-MUC2 (Abcam, cat. no. ab11197) and -MUC5AC (Sigma-Aldrich, cat. no. WH0004586M7) respectively. Secondary goat anti-mouse antibody (Genscript, cat. no. A00160) was diluted at 1:2500. To check protein quantity on the membranes, a separate, identical membrane was blotted and incubated for 10 min. in Ponceau Red (Honeywell Fluka). Next, the blot was washed in demi-water and signals were quantified using the ChemiDoc MP system. Dot Blots with anti-MUC2 and -MUC5AC were quantified by measuring the density of the first six dots (rows) using ImageJ software. A density-based linear trendline was calculated from the second to the sixth dot. The coefficients (per µg/mL) were corrected for Ponceau Red density. Ponceau Red signals were quantified by measuring density of the first dot (first row) only. Biological replicates per conditions were n = 2 for HT29-MTX-E12, static, n = 3 for HT29-MTX-E12, SWMS, n = 3 for Caco-2 (static and SWMS), and n = 1 for LS174T.

### pH, lactate and glucose measurements

Every time medium of Transwells was refreshed, conditioned medium was collected from HT29-MTX-E12 cells and stored at -20 °C until further processing. Medium of apical and basolateral compartments were collected separately, but compartments were pooled per time point and condition. Samples were spun down and 200 µL of supernatant was transferred to a 96-wells plate. After stabilization, absorbance was measured at 415 and 560 nm at 5% CO<sub>2</sub> in a Synergy Neo2 Hybrid Multi-Mode Reader with a CO<sub>2</sub> and O<sub>2</sub> gas controller (1210013) (BioTek Instruments). Aliquots of growth medium (ca. 5 mL) were used for preparation of a standard curve with pH values ranging from 2.6 to 9.9. Lactate and glucose were quantified with a Shimadzu LC2030C-Plus high-performance liquid chromatography (HPLC) system equipped with a Shodex SH1821 column kept at 45 °C and running 0.01 N sulfuric acid as eluent (1 mL/min). Compounds were detected by determining the refractive index and identified using pure lactate and glucose as external standards and crotonate as an internal standard.

### Statistical analysis

Statistical analysis of microarray data is described above. Data distribution for other (continuous) outcomes was tested with the D'Agostino-Pearson omnibus normality test using GraphPad Prism (San Diego, CA, USA). Significance of differences between two conditions was analysed using a two-tailed, unpaired Student's t-test. For non-normally distributed data, a Mann-Whitney U test was used. The data are presented as mean  $\pm$  standard deviation. A  $p$ -value of  $\leq 0.05$  was considered significant. Unless stated otherwise, all experiments were performed in triplicate.

## Results

### Gene expression changes in HT29-MTX-E12, Caco-2 and LS174T cells

To investigate SWMS-specific effects leading to higher mucus production of the SWMS culturing method, HT29-MTX-E12 cells were grown for 14 days under static and SWMS conditions (after cell seeding and attachment), and microarray analysis was performed on mRNA of the cells. We included Caco-2 cells, a non-mucus producing cell line, grown on Transwell membranes under static and SWMS conditions for 14 days as a reference control. The LS174T cell line was used as a control for a mucus-producing cell line. Multilevel principal component analysis performed on the 500 most variable genes showed a strong clustering of the biological replicates per cell type with a clear separation of the three cell lines (**Supplementary Fig. 1A**). A number of 6,732 and 7,013 genes were differentially regulated between SWMS and static conditions in HT29-MTX-E12 and Caco-2 cells, respectively ( $p < 0.05$ ) (**Supplementary Fig. 1B-D**).

### Increased MUC2/MUC5AC ratio in SWMS-cultured HT29-MTX-E12 cells

We investigated the expression of genes encoding for mucins in HT29-MTX-E12 cells, since we know from previous studies that culturing this cell type under SWMS conditions led to increased MUC2 production (25). Indeed, in our study, SWMS conditions resulted in a significant 1.42-fold upregulation of *MUC2* ( $p < 0.05$ ) (**Fig. 1A**). Expression of gel-forming mucins *MUC5AC* and *MUC5B* was decreased in response to SWMS (FC = -1.56 and -1.84, respectively,  $p < 1 \cdot 10^{-4}$ ) (**Fig. 1A, Supplementary File 1**). Transmembrane mucins were also significantly lower expressed after SWMS conditions (**Fig. 1A**). *MUC3A*, 13, 17, 20 and 21 showed FC values between -1.52 and -2.32 (**Supplementary File 1**). Eight out of 19 mucins (*MUC4*, 6, 7, 12, 15, 16, 19 and 22) displayed very low expression levels under both static and SWMS conditions (RMA < 4) and were not significantly differentially expressed (**Supplementary File 1**). Taken together, these data indicate that SWMS conditions resulted in a change in expression

of mucin encoding genes with an increased expression of *MUC2*, while other gel-forming as well as transmembrane mucins were significantly lower or not differentially expressed. Dot Blot data supported microarray data for *MUC2*, as protein levels also showed a significant upregulation ( $p < 0.05$ ) under SWMS versus static conditions (**Fig. 1B and Supplementary Fig. 2A and C**). Less *MUC5AC* was detected under SWMS conditions, however, variation between replicates was rather high and differences were not significant ( $p = 0.20$ ) (**Fig. 1B and Supplementary Fig. 2B and C**). Overall, HT29-MTX-E12 cells grown under SWMS conditions showed a significantly increased *MUC2*/*MUC5AC*-ratio (Fig. 1C,  $p < 0.05$ ), confirming previous findings (25). For LS174T, which we included as a control cell line reported to produce predominantly *MUC2*, a relatively high *MUC2*/*MUC5AC* ratio was calculated (**Supplementary Fig. 2D-E**). In contrast, Caco-2 cells, which are not reported to produce mucus, showed low RMA values ( $< 5$ ) for *MUC2* and *MUC5AC* and protein expression of these mucins was below detection level in both conditions (**Supplementary Fig. 2A-C**). Furthermore, similar to HT29-MTX-E12 cells, SWMS conditions resulted in significant downregulation of *MUC20*, *MUC3A* and *MUC13* in this cell line (**Supplementary File 1**).

#### Upregulation of genes and pathways related to cell cycle, cell growth and cell proliferation in cells cultured under SWMS conditions

As both HT29-MTX-E12 and Caco-2 cell lines were subjected to SWMS conditions and grown under static conditions, we compared the genes up- or downregulated in both cell lines. Of the 2,844 significantly differentially expressed genes in both cell lines, 353 genes (12.4 % of shared total significantly regulated genes) were upregulated by 1.5-fold or higher in both cell types due to the SWMS conditions. A total of 180 genes (6.3 %) were significantly downregulated by 1.5-fold or higher in both cell lines and a total of 98 genes showed opposite effects when comparing the two cell lines (**Supplementary Fig. 3**). Interestingly, among the shared upregulated genes, a number of cell cycle related genes was included. Moreover, the top 10 most upregulated genes of HT29-MTX-E12 cells under SWMS versus static conditions was dominated by genes related to cell growth, cell motility and cell proliferation, i.e. *KIF14*, *KIF20A*, *DEPDC1*, *DLGAP5* and *SPC25* (**Table 1**). Gene Set Enrichment Analysis (GSEA) also revealed that most significantly enriched upregulated pathways were dominated by cell cycle and DNA replication related pathways (**Table 2**). Furthermore, marker of proliferation Ki-67 (*MKI67*) was 5.03-fold upregulated by SWMS culturing conditions ( $p < 1 \cdot 10^{-10}$ ) in HT29-MTX-E12 and 2.33-fold in Caco-2 cells ( $p < 1 \cdot 10^{-5}$ ) (**Supplementary Fig. 4A**). Additionally,

we found higher cell counts at day 15 under SWMS compared to static conditions in both cell lines (**Supplementary Fig. 4B**), confirming that SWMS conditions lead to an increase in cell proliferation. Altogether, these data indicate that SWMS conditions result in the activation of cell proliferation pathways compared to static conditions, independent of cell type.

**Table 1** Top 10 strongest up- and downregulated genes in HT29-MTX-E12 cells grown under SWMS versus static conditions.

### Expression of target genes involved in Notch- and Atoh-key pathways did not point towards a favoured cell differentiation state by SWMS conditions

Next to the marked effects of SWMS conditions on cell proliferation in both HT29-MTX-E12 and Caco-2 cells, we took a closer look at the effects on intestinal cell differentiation. Key regulators in this process belong to the Notch/Atoh signalling pathway (49, 50). When it comes to cell differentiation, Notch and Atoh have opposing roles: Notch activation promotes absorptive cell differentiation, while Atoh activation favours differentiation into secretory cell types (49-51). Interestingly, in our transcriptomic dataset, both *NOTCH1* and *ATOH1* were significantly upregulated by SWMS conditions in HT29-MTX-E12 cells (FC = 1.61,  $p < 0.001$  and FC = 1.64,  $p < 0.01$ , respectively) and the latter also in Caco-2 cells (FC = 2.09,  $p < 0.001$ ). The stem cell marker *LGR5*, which is known to be part of a positive feedback loop regulated by Notch (52), was significantly upregulated by SWMS conditions in HT29-MTX-E12 cells (FC = 2.33,  $p < 1 \cdot 10^{-5}$ ), although RMA values were below 5. In Caco-2 cells, *LGR5* had higher RMA values and was even stronger upregulated (FC = 4.37,  $p < 1 \cdot 10^{-7}$ ). Further downstream the Notch pathway, the target genes Hairy and enhancer of split (HES) family members *HES1* and *HES6* were both significantly upregulated by SWMS conditions in HT29-MTX-E12 cells (FC = 1.24,  $p < 0.05$  and FC = 2.08,  $p < 1 \cdot 10^{-5}$ , respectively). Apart from Cyclin D1 (*CCND1*) (FC = -1.51,  $p < 1 \cdot 10^{-6}$ ) no other Notch-target genes were significantly differentially expressed. Regarding the Atoh pathway, the downstream target gene Neurogenin 3 (*NEUROG3*) was 2.07-fold and 2.41-fold higher expressed ( $p < 0.001$ ) in HT29-MTX-E12 and Caco-2 cells, respectively. Other Atoh target genes,

such as *SPDEF* and *GFI1* were not differentially expressed between SWMS and static conditions in both cell types. Altogether, these transcriptomic data show that some target genes of both the Notch and Atoh pathway were differentially expressed in HT29-MTX-E12 and Caco-2 cells. However, these data do not point towards a favoured differentiation state (absorptive versus secretory cell fate).

### Downregulation of KLF4 at both gene and protein level under SWMS conditions in HT29-MTX-E12 and Caco-2 cells

Another Notch-target involved in differentiation of progenitor cells into goblet cells is KLF4 (53). Given the secretory, goblet cell-like phenotype of HT29-MTX-E12 grown under SWMS conditions, the significant downregulation of *KLF4* (FC = -1.86,  $p < 0.0001$ ) is interesting. Acting as both a transcriptional repressor and activator in the gastrointestinal epithelium, this zinc-finger transcription factor plays a critical role in the decision between proliferation and cell cycle arrest/differentiation (54). We validated the downregulation of KLF4 under SWMS conditions at protein level using Western Immunoblotting. Indeed, when cultured under SWMS conditions, the expression of KLF4 protein was lower compared to the static conditions in both cell lines (Fig. 2A-B and Supplementary Fig. 5).

**Figure 2 Protein expression of KLF4 in HT29-MTX-E12, Caco-2 and LS174T cells grown under static and/or SWMS conditions. A)** Western Blot results of KLF4 and HSP90 (house-keeping protein) in Caco-2, HT29-MTX-E12 and LS174T-cells grown under static and SWMS conditions or static only (LS174T). Of each condition, one representative biological replicate is shown. See Supplementary Fig. 5 for all replicates. **B)** KLF4 protein quantity expressed as the protein band density relative to HSP90. \*  $p < 0.05$ ,  $n = 3$ .

We next investigated whether this downregulation of KLF4 resulted in differential expression of target genes of KLF4, as identified in literature (55). Among the most strongly regulated are genes related to cell-cycle control or essential for cell proliferation and differentiation, including cyclin B1 (FC = 6.59,  $p < 1 \cdot 10^{-13}$ ) (56), cyclin E2 (FC = 2.03,  $p < 0.001$ ) (57, 58), ornithine decarboxylase (FC = 1.80,  $p < 1 \cdot 10^{-7}$ ) (59), cyclin E1 (FC = 1.62,  $p < 1 \cdot 10^{-4}$ ) (57, 58), cyclin D1 (FC = -1.51,  $p < 1 \cdot 10^{-6}$ ) (60, 61) and cyclin D2 (FC = 1.85,  $p < 0.001$ ) (62). A non-exhaustive list of genes (in)directly related to KLF4 is provided in Supplementary File 1.

### Minor effect on intestinal epithelial barrier integrity, but difference in appearance of cells grown under SWMS conditions

To investigate the effects of SWMS conditions on intestinal epithelial barrier integrity, transepithelial electrical resistance (TEER) was measured at multiple time points during culturing. TEER values of HT29-MTX-E12 cells increased steadily over time and no clear effects were observed between static and SWMS conditions (**Fig. 3A**). For Caco-2 cells, the TEER of the cells grown on SWMS conditions increased steeply during the first seven days of culturing and decreased gradually afterwards, while the TEER of cells grown on static conditions was relatively stable (**Fig. 3B**).

**Figure 3 Transepithelial electrical resistance (TEER) of HT29-MTX-E12 and Caco-2 cells grown under static and SWMS conditions up to 14 days.** TEER was measured at  $t = 4, 7, 9, 11$  and 14 days and expressed in  $\text{Ohm}/\text{cm}^2$  in **A)** HT29-MTX-E12 and **B)** Caco-2 cells. \*  $p < 0.05$ ; \*\*  $p < 0.01$ ; \*\*\*  $p < 0.001$ ;  $n = 3$ .

Based on available literature, we compiled a panel of genes responsible for epithelial barrier integrity (**Supplementary File 1**). Except for a 3.33-fold increase in expression of Catenin alpha like 1 (*CTNNAL1*) in HT29-MTX-E12 cells under SWMS conditions ( $p < 1 \cdot 10^{-9}$ ), only a low number of significantly differentially expressed genes was found for both HT29-MTX-E12 and Caco-2 cells (**Supplementary File 1**). Together, these results indicate that SWMS conditions had negligible effects on TEER in both HT29-MTX-E12 and Caco-2 cells, which was reflected by the relatively low number of significantly differentially expressed genes related to cell integrity. Interestingly, a clear difference in cell appearance on the Transwell membranes was observed for both cell types at the time cells were harvested, as cells grown under SWMS conditions seemed to concentrate in the center of the membrane (**Fig. 4A-B**).

**Figure 4 Images of HT29-MTX-E12 and Caco-2 cells grown under static and SWMS conditions up to 14 days. A)** Pictures of HT29-MTX-E12 and Caco-2 cells grown under static and SWMS conditions at  $t = 15$  days. **B)** Bright-field microscopy pictures of HT29-MTX-E12 and Caco-2 cells grown under static and SWMS condition, focussed on the centre of the Transwell membranes.

#### Downregulation of Trefoil Factor genes in HT29-MTX-E12 cells grown under SWMS conditions

When focusing on the most significantly downregulated genes in HT29-MTX-E12 grown under SWMS compared to static conditions, Trefoil Factor 2 (*TFF2*) was most strongly downregulated ( $FC = -15.75$ ,  $p < 1 \cdot 10^{-12}$ ) (**Table 1**). Although to a lesser extent, *TFF1* and *TFF3* were also significantly downregulated (**Fig. 5**). Trefoil factors are small cysteine rich peptides and form a family of mucin-associated secretory molecules involved in many physiological processes to maintain and restore gastrointestinal mucosal homeostasis (Reviewed in Aihara *et al.* (63)). TFF peptides are known to auto- and cross-regulate their expression via the epidermal growth factor receptor *in vitro* (63, 64). However, *EGF1* was not significantly differentially expressed between culture conditions in HT29-MTX-E12 cells in our dataset. On the contrary, the gene encoding Epidermal growth factor receptor (*EGFR*) was significantly downregulated by 1.42-fold ( $p < 0.0001$ ).

**Figure 5 TFF gene expression in HT29-MTX-E12 cells grown under static and SWMS conditions.** Microarray expression values (Log2) of *TFF1*, 2 and 3 and the corresponding fold change (FC). \*\*\*\*  $p < 0.0001$ ;  $n = 3$ .

#### Different regulation of ion transporters under SWMS conditions in both HT29-MTX-E12 and Caco-2 cells

Since ion transport has proven crucial in (intestinal) mucus production (65), we explored the effect of SWMS conditions on the expression of ion transporters and exchangers. The gene encoding Cystic Fibrosis transmembrane regulator (CFTR), a chloride and bicarbonate transporter expressed on the apical side of (intestinal) epithelial cells and demonstrated to be indispensable for normal mucus production (66), was significantly upregulated in HT29-MTX-E12 cells grown under SWMS conditions (FC = 1.68,  $p = < 0.00001$ ). Other ion transporters that were significantly regulated under SWMS conditions in HT29-MTX-E12 and Caco-2 cells include *NBCe1/SLC4A4*, encoding a basolateral  $\text{Na}^+/\text{HCO}_3^-$  importer (FC = -1.95,  $p < 0.01$  in HT29-MTX-E12) and *NHE1/SLC9A1*, encoding a basolateral  $\text{Na}^+/\text{H}^+$  exchanger (FC = -1.59,  $p < 1 \cdot 10^{-5}$ ). Additionally, the significant downregulation of *DRA/SLC26A3*, encoding an apical  $\text{Cl}^-/\text{HCO}_3^-$  exchanger (FC = -1.25,  $p < 0.05$ ) under SWMS conditions is interesting, given its importance in intestinal salt and fluid absorption (67). This gene is, however, not highly expressed in HT29-MTX-E12 cells (RMA < 3). Whereas GSEA revealed that the pathway "Mineral absorption" was not significantly regulated in HT29-MTX-E12, interestingly, this pathway was the most enriched among all downregulated pathways in Caco-2 cells (NES = -2.58, FDR q-value = 0.00, **Supplementary File 2**). These cells also showed relatively strong and significant regulation of aforementioned ion transporters (FC = 1.78,  $p < 1 \cdot 10^{-8}$  for *CFTR*, FC = -2.03,  $p < 1 \cdot 10^{-6}$

for *NBCe1*,  $FC = -1.33$ ,  $p < 0.01$  for *NHE1* and  $FC = -3.18$ ,  $p < 1 \cdot 10^{-8}$  for *DRA*). All in all, culturing under SWMS results in significant regulation of several key ion transporters in both HT29-MTX-E12 and Caco-2 cells.

#### Lower glucose consumption and lactate production per cell in HT29-MTX-E12 cells grown under SWMS conditions

The observed visible colour difference of cell medium in HT29-MTX-E12 cells, accompanied by significant regulation of  $H^+$  and  $HCO_3^-$  transporters, could indicate a difference in cell medium pH between growth conditions. The pH of the medium samples collected during every refreshment remained similar between the apical and basolateral compartment in both conditions. During the first 13 days, pH decreased to a similar extent in both conditions. Under SWMS conditions, the pH remained relatively stable over time after one week, whereas static conditions showed a decreased pH at  $t = 14$  days in the apical compartment (difference of 0.2) (**Supplementary Fig. 6A-B**). At  $t = 15$  days, one day after the last medium refreshment, trends reversed and medium of static conditions showed a significantly higher pH compared to SWMS conditions in both compartments (difference of 0.2) (**Fig. 6A-B** and **Supplementary Fig. 6A, C and D**).

**Figure 6** pH values of medium collected at  $t = 15$  days from HT29-MTX-E12 cells grown under static and SWMS conditions. Medium pH of **A**) apical and **B**) basolateral compartments of HT29-MTX-E12 cells grown under static and SWMS conditions at  $t = 15$  days. \*  $p < 0.05$ ; \*\*  $p < 0.01$ ,  $n = 3$ .

A decrease in pH could be explained by increased lactate production and subsequent acidification of the medium. Indeed, pH of cell medium showed opposite trends to the amount of lactate measured in the medium, i.e. lactate concentrations increased with decreasing pH values and remained stable for SWMS conditions (**Supplementary Fig. 7A**). As medium volumes were, however, different between static and SWMS conditions, we calculated total lactate production and glucose consumption per well. Cell medium collected from cells grown under static conditions showed significantly higher lactate production at  $t = 7-14$  days (**Supplementary Fig. 7B**), accompanied with no difference in total glucose consumption per well (**Supplementary Fig. 7C**), indicating a lower amount of lactate produced per mole glucose under SWMS conditions. At  $t = 15$  days, one day after the last medium change (at which not all glucose had been consumed yet), lactate production was similar between conditions (**Fig. 7A**). On the contrary, cells grown under SWMS conditions had consumed significantly more glucose (**Fig. 7B**), again resulting in a lower lactate-per-glucose ratio under SWMS conditions. After correction for cell count at  $t = 15$  days, glucose consumption and lactate production per cell were still significantly lower under SWMS conditions (**Fig. 7C-D**,  $p < 0.001$ ), resulting in a significantly lower lactate-per-glucose ratio (**Fig. 7E**).

**Figure 7** Lactate production and glucose consumption by HT29-MTX-E12 grown under static and SWMS conditions. **A)** Total lactate (micromole) produced per well in medium collected from apical and basolateral compartments of HT29-MTX-E12 cells grown under static or SWMS conditions, at t = 15 days. **B)** Total glucose (micromole) consumed per well from medium collected from apical and basolateral compartments of HT29-MTX-E12 grown under static and SWMS conditions, at t = 15 days. **C)** Glucose consumption (picomole) per cell by HT29-MTX-E12 grown under static and SWMS conditions at t=15 days. **D)** Lactate production (picomole) per cell by HT29-MTX-E12 grown under static and SWMS conditions at t = 15 days. **E)** Ratio of lactate produced glucose consumed per cell in HT29-MTX-E12 grown under static and SWMS conditions at t = 15 days. \* p < 0.05; \*\* p < 0.01; \*\*\* p < 0.001, n = 3.

Lower glucose consumption under SWMS conditions coincided with a significantly lower expression of *GLUT1/SLC2A1*, encoding a transmembrane glucose transporter ( $FC = -1.46, p < 1 \cdot 10^{-7}$ ) and *HK2*, encoding the glycolytic enzyme hexokinase 2 ( $FC = -2.18, p < 1 \cdot 10^{-8}$ ). GSEA revealed, however, no significant enrichment of the “Carbohydrate absorption pathway” or “Glycolysis pathway” in HT29-MTX-E12 cells cultured under SWMS conditions. Interestingly, however, both pathways were among the top-10 enriched downregulated in Caco-2 cells (NES “Carbohydrate absorption” = -2.35,  $p = 0.00$  and NES “Glycolysis pathway” = -2.12,  $p < 1 \cdot 10^{-3}$ , respectively). As shown previously for similar models, these data could point towards a more aerobic cell metabolism under SWMS conditions (40-44). This is further supported by a significant downregulation of the “HIF1-signalling pathway” in both HT29-MTX-E12 and Caco-2 cells, as revealed by GSEA (NES = -1.79, FDR q-value = < 0.05 and NES = -2.30, FDR q-value = 0.01, respectively).

## Discussion

In the present study, we aimed to further characterize the potential mechanisms underlying the increased mucus production by the SWMS culture method as described by Navabi *et al.* (25). To this end, we cultured HT29-MTX-E12 cells under both static and SWMS conditions and performed microarray analysis to investigate changes in gene expression by taking both a targeted and untargeted approach. First, we aimed to validate the increased mucus production under SWMS conditions. Indeed, SWMS conditions induced higher *MUC2* expression in HT29-MTX-E12 cells, which was also reflected at the protein level. It seemed that the increase in *MUC2* occurred at the expense of *MUC5AC*, since both gene and protein expression of this mucin was decreased. This resulted in a significantly increased *MUC2/MUC5AC* ratio, confirming previous findings (25). An overview of the most prominent changes observed at *t* = 15 days is graphically summarized (Figure 8).

**Figure 8 Graphical summary of effects observed in HT29-MTX-E12 cells grown under SWMS compared to static conditions at *t* = 15 days.** HT29-MTX-E12 cells were grown on Transwell under static and SWMS conditions. The most important changes between static and SWMS at *t* = 15 days are depicted. *MUC2/MUC2* = mucin 2; *MUC5AC/MUC5AC* = mucin 5; *TFF1/2/3* = trefoil factor 1/2/3; *SLC9A1 (NHE1)* =  $\text{Na}^+/\text{H}^+$  Exchanger 1; *SLC4A4 (NBCe1)* =  $\text{Na}^+/\text{HCO}_3^-$  cotransporter 1; *CFTR* = Cystic Fibrosis transmembrane conductance regulator; lactate:glucose = amount of lactate (mole) produced per mole of glucose consumed in conditioned medium; *SLC2A1 (GLUT1)* = Glucose Transporter Type 1; *HK2* = Hexokinase 2; *KLF4/KLF4* = Kruppel like factor 4; *EGFR* = epidermal growth factor receptor; *NOTCH1* = Notch receptor 1; *ATOH1* = atonal BHLH transcription factor 1; *MKI67* = marker of proliferation Ki-67; TEER = transepithelial electrical resistance.

The transcriptomic analysis of HT29-MTX-E12 cells revealed that SWMS conditions resulted in a strong upregulation of genes and pathways related to cell cycle regulation. In line with this finding, we found higher cell numbers after SWMS culturing. Although the effect size was lower, similar results were found in Caco-2 cells. Similar to our results, a previous study using ALI – which is similar to the semi-wet interface part of SWMS conditions – also showed an increase in cell number and cell layer thickness in intestinal porcine epithelial cells (39), and increased cell proliferation in intestinal organoids (68). Our experiments can, however, not answer whether the higher cell count is due to an increased height and/or a columnar shape of cells grown under SWMS, as seen in both ALI and SWMS cultures (25, 39) or due to stacking of the cells, although the concentration of cells in the centre of the well point to the latter. In any case, the shared upregulation of cell cycle-related pathways between colon carcinoma cell lines that are so different at the transcriptomic level (69), emphasizes the SWMS-specific effect on cell growth, independent of the cell type. As cell culturing conditions may also strongly influence cell morphology and tight junction formation (70), we explored if the SWMS method resulted in an increased resistance over the epithelial membrane by performing TEER measurements. TEER values of HT29-MTX-E12 cells were comparable to results from earlier studies (24, 71). No differences were found between SWMS and static conditions for HT29-MTX-E12 cells during the culturing period, which was supported by the low number of differentially regulated genes related to intestinal barrier integrity. These findings are opposing the results from Navabi *et al.*, as they found a slight, but significant, increase in TEER values of HT29-MTX-E12 cells cultured under SWMS conditions. However, apart from the fact that measurements were performed at 21 days, Navabi *et al.* also used a different device (Ussing chamber) for TEER measurements. Furthermore, the higher concentration of cells in the centre of the Transwell as a result of SWMS conditions may have resulted in an underestimation of TEER values, as the chopstick electrodes do not measure the resistance over the whole membrane.

In parallel to cell proliferation, we also investigated the potential change in cell differentiation pathways as a result of the SWMS method. We focussed on the Notch/Atoh1 pathways, since these are key pathways in the decision between epithelial cell development into either absorptive or secretory cell types (51). Given the MUC2-promoting effects of SWMS conditions in HT29-MTX-E12 cells, we hypothesized that SWMS conditions inhibited Notch and promoted Atoh1, thereby favouring the differentiation of secretory goblet cells. The interplay between Notch and Atoh in the context of goblet cell differentiation was underscored by the effect of the  $\gamma$ -secretase inhibitor DAPT, which further enhanced mucus production in HT29-MTX-E12 cells by indirectly inhibiting Notch, and thus promoting goblet cell differentiation (25). Although we found a number of significantly differentially

expressed target genes of both Notch and Atoh1, the results did not point towards one particular overrepresented pathway. Based on these results, we suppose that the increased MUC2 production in HT29-MTX-E12 cells was not the result of a change towards a favoured secretory cell fate. This was further supported by a significant downregulation of the goblet cell marker KLF4 at both protein and gene level. The downregulation of *KLF4/KLF4*, identified as a cell cycle checkpoint protein and negative regulator of cell growth (72, 73), matches with the observed increased cell cycle regulation under SWMS conditions. However, based on our results, we cannot identify cause-effect relations and point at the exact trigger that led to decreased *KLF4/KLF4* expression.

The three members of the TFF family (*TFF1*, *TFF2*, *TFF3*) were all strongly downregulated under SWMS conditions in HT29-MTX-E12 cells. *TFF1* and *TFF2* are predominantly expressed in the stomach and duodenum in humans (74-76), whereas *TFF3* is mostly expressed in the small intestine and colon (77, 78). It is likely that our study confirms the previous finding that *TFF1* and *MUC5AC* co-localize (79, 80), as both genes were highly expressed in HT29-MTX-E12 cells. Moreover, the strong and significant downregulation of both *TFF1* and *MUC5AC* induced by SWMS conditions emphasizes the simultaneous regulation of these genes by the SWMS method. *TFF3* is known to co-localize with *MUC2*, however, these genes had opposite expression profiles. Interestingly, *TFF* expression is regulated by EGFR (64), of which the encoding gene was found downregulated in our transcriptomic dataset. Besides, EGFR activation was implicated in the production of MUC5AC in airway epithelial cells (81). However, the exact role of EGFR in the SWMS model remains elusive.

Proper mucus production depends on the activity of ion transport (65) and ALI-models with other cell types have shown changes in ion transport (42, 82-84). Therefore, the significant regulation of several key ion transporters in both HT29-MTX-E12 and Caco-2 cells in our microarray analysis, is interesting. It should be considered, however, that the microarray results are limited to one time point; in this case at which a lower pH is measured under SWMS versus static conditions. Therefore, we cannot conclude whether the change in mucus phenotype can be (partially) explained by differential regulation of ion transporters, or that this regulation is a consequence of the microclimate at the timepoint of analysis. Moreover, our method to measure pH did not allow us to measure potential local pH differences, as seen *in vivo* (85), which could further clarify the observed changes.

It has been demonstrated previously that both the semi-wet conditions/ALI and the mechanical stimulation part of SWMS separately, support a more aerobic cell culture environment in non-intestinal cell lines (41-44). More recent studies confirmed increased oxygen supply and oxidative phosphorylation, concomitant with suppressed glycolysis in intestinal epithelial cells from porcine origin (39, 40). Similar to the study by Klasvøgt *et al.* (40), we measured significantly lower lactate

levels and decreased glucose consumption in HT29-MTX-E12 cells grown under SWMS conditions. Interestingly, as opposed to Klasvagt *et al.*, we did not find a downregulation of the HIF-1 $\alpha$  gene, but GSEA revealed significant enrichment of the HIF-1 signalling pathway among the downregulated pathways in both HT29-MTX-E12 and Caco-2 cells. This, together with the significantly decreased lactate-per glucose ratio, suggests that under SWMS conditions, cells switch to a more aerobic cell metabolism. Increased mucus production has been observed in other ALI-models (without mechanical stimulation), such as murine gastric surface mucous cells (44) and airway cells from different origins (86). *MUC5AC* was suggested to be transcriptionally regulated by HIF-1 $\alpha$  in airway cells (87, 88), which indicates the possible involvement of HIF-1 $\alpha$  in the downregulation of *MUC5AC* on both gene and protein level under SWMS conditions. In contrast, hypoxia was shown to enhance *HIF-1 $\alpha$* -binding to the *MUC2* promoter, resulting in increased *MUC2* mRNA and protein levels. However, this effect was transient, as *MUC2* protein levels restored again after 24 hours, while hypoxic conditions were still applied (89). In any case, the increased *MUC2* levels in our study cannot directly be explained by the observed downregulation of HIF-1 $\alpha$ .

Mechanical stimulation as part of the SWMS conditions, induced by continuous shaking at 65 rpm, led to a continuous exposure to shear stress. In a model highly similar to SWMS, the shear stress value was calculated to be  $1.6 \times 10^{-2} \pm 4.7 \times 10^{-3}$  dyne/cm<sup>2</sup> (90). In other *in vitro* and *ex vivo* models, shear stress values between  $1.3$  and  $2.0 \times 10^{-2}$  dyne/cm<sup>2</sup> were sufficient to increase *MUC2* protein or gene expression in Caco-2 cells, colon organoids or enteroids compared to static conditions (26, 91). We were able to replicate the increase in *MUC2* gene and protein levels in HT29-MTX-E12, but not in Caco-2 cells, although we cannot be certain if the shear stress induced by mechanical stimulation was responsible for this observation. Importantly, cell culture conditions in aforementioned models were different than the SWMS conditions, as medium is continuously replenished, whereas under SWMS conditions, medium is refreshed every 2 or 3 days (but still constantly redistributed due to mechanical stimulation). Besides, in some of the models mentioned above, laminar flow is applied using external pumps resulting in a constant flow, which is a different approach than the circular shaking motion under SWMS conditions. Signalling pathways involved in the response of intestinal cells to mechanical forces were not significantly regulated in our study (92). Shear stress was also demonstrated to stimulate differentiation of intestinal epithelial cells (26, 91, 93, 94). Interestingly, next to its role in cell differentiation and cell cycle arrest (95), KLF4 is also known as a mechanosensitive transcription factor in vascular endothelial cells (96), osteoblasts (97) and a dermal cell line (98), in a context-dependent manner. To the best of our knowledge, there is no literature available providing evidence for a link between shear stress and KLF4 in intestinal tissues or models.

An important limitation of our study is that our microarray was restricted to a single time point, whereas our study aimed to capture an overview of the cellular processes affected by the SWMS culture method. To increase insight in gene expression over time (e.g. with regard to cell proliferation or mucus production), future studies should include multiple time points. Another limitation is that gene expression does not always match with protein expression or activity, though protein levels of MUC2, MUC5AC and KLF4 supported the changes observed at gene levels in both HT29-MTX-E12 and Caco-2 cells. Apart from technical limitations of our study, we demonstrate that HT29-MTX-E12 cells grown under SWMS conditions, as a model developed to better represent the *in vivo* intestine in terms of MUC2 and cell morphology (25) still has its limitations. For instance, the downregulation of genes encoding other mucus-associated proteins, such as TFF3, suggest a less representative mucus layer in terms of whole mucus composition. This could limit the use of this model to further functionally characterize the intestinal mucus layer at a molecular level and to exploit the myriad of *in vivo* functions of mucus. Still, the function of the SWMS-produced mucus layer as a physical barrier was demonstrated by its interference with the genotoxic activity of colibactin, a toxin produced by certain *Escherichia coli* strains (30). In a similar fashion, the model could be applied to evaluate the diffusion of drugs and other particles (100). Furthermore, with MUC2 being the main component, the model could be useful to study interactions with both pathogenic and commensal bacteria, but would further require quantification of the mucin glycans present, as these have demonstrated to play a crucial role in mucin-microbe interactions (101).

Altogether, we confirm the usefulness of SWMS cell culture conditions to improve the *in vivo* representation of the mucus layer *in vitro*, with regard to the increase in intestinal mucin MUC2. Our study provides insight in potential underlying processes, which might ultimately lead to a step-by-step improvement of the representativeness of the *in vitro* mucus layer. For instance, our study demonstrates upregulation of cell cycle regulation, downregulation of KLF4, differential regulation of ion transporters and increased aerobic metabolism of cells cultured under SWMS versus static conditions. Further research should also focus on the qualitative aspects of the *in vitro* mucus layer, for example with regard to mucin glycosylation, disulphide bonds that assure firmness of the mucus, and the contribution of other proteins present in the mucus layer, such as TFFs, as observed *in vivo*.

# Supplemental material

**Supplementary figure 1 Overview microarray results in HT29-MTX-E12, Caco-2 and LS174T cells grown under static and/or SWMS conditions. A)** Multilevel principal component analysis (PCA) of the 500 most variable genes. **B)** Number of differentially expressed genes between SWMS and static conditions in HT29-MTX-E12 and Caco-2 cells (IBMT  $p < 0.05$ ). **C)** Volcano plot highlighting the Log Fold Change (logFC) on the x-axis and the corresponding p-values ( $-\log_{10}$ ) on the y-axis for the comparison SWMS versus static conditions in HT29-MTX-E12 cells and **D)** Caco-2 cells.  $n = 3$ .

**Supplementary figure 2** Overview of Dot Blot results for **A)** MUC2 and **B)** MUC5AC including Caco-2 and HT29-MTX-E12 cells cultured under static and SWMS conditions and LS174T cells. A concentration of 68.2 µg/mL was blotted and six times serially diluted 1:2. In the bottom row, PBS was used as a negative control. **C)** Images of Ponceau Red staining (colorimetric and photographic) that were used as reference for total protein content. Protein density was based on the colorimetric image. **D)** Protein expression of MUC2 and MUC5AC in LS174T cells, expressed as density (a.u.) per ug/mL protein blotted, after correction of Ponceau Red density. **E)** Ratio of MUC2 and MUC5AC protein expression in LS174T cells.

Up =  $FC \geq 1.5$   
Down =  $FC \leq -1.5$

## Top 20 upregulated genes shared between HT29-MTX and Caco-2

Gene name	FC in HT29-MTX	p-value	FC in Caco-2	p-value	Gene function

<i>LRP1</i>	-1.55	0.00	-1.66	0.00	LDL receptor related protein 1

**Supplementary figure 3** Venn diagram showing the number of shared and unique differentially expressed up- and downregulated genes ( $-1.5 \geq \text{Fold change} \geq 1.5$  between HT29-MTX-E12 and Caco-2 cells cultured under static and SWMS conditions. The top 20 up- and downregulated genes shared between HT29-MTX-E12 and Caco-2 cells is given in the tables.

**Supplementary figure 4 A)** Microarray gene expression values (Log2) of MKI67 in HT29-MTX-E12 and Caco-2 cells cultured under static and SWMS conditions. **B)** Cell count after t=15 days, expressed as cells per cm<sup>2</sup>, of HT29-MTX-E12 and Caco-2 cells cultured under static and SWMS conditions. \*\*\*\* p < 0.0001.

**Supplementary figure 5** Western Immunoblotting results of KLF4, including all three biological replicates (batch 1, 2 and 3) in Caco-2, HT29-MTX-E12 and LS174T-cells grown under static and SWMS conditions or static only (LS174T). HSP90 was used as house-keeping protein.

A

B

C

D

**Supplementary figure 6 A)** Ratio of Absorbance of cell culture medium (415 and 560 nm) of HT29-MTX-E12 and Caco-2 cells under static and SWMS conditions measured at 5% CO<sub>2</sub>. **B)** Medium pH of apical and basolateral compartments of HT29-MTX-E12 cells grown under static and SWMS conditions at t = 1-14 days. \* p < 0.05; \*\* p < 0.01, n = 3 **C)** Standard curve of pH values and absorbance values of cell culture medium measured at 415/560 nm at 5% CO<sub>2</sub>. **D)** The linear part the standard curve, including trendline.

A

**Supplementary figure 7 A)** Lactate concentration (mM) in cell culture medium of HT29-MTX-E12 cells collected during every medium refreshing moment. **B)** Total lactate (micromole) produced per well in medium collected from apical and basolateral compartments of HT29-MTX-E12 grown under static or SWMS conditions, at  $t = 1-14$  days. **C)** Total glucose (micromole) consumed per well from medium collected from apical and basolateral compartments of HT29-MTX-E12 grown under static and SWMS conditions, at  $t = 1-14$  days.

**Supplementary file 1** Panels of genes, including mucins, cell integrity-related genes, KLF4-related genes and genes related to ion transport in HT29-MTX-E21 and Caco-2 cells. The fold changes and p-values between SWMS and static conditions are given.

ATP1A1	5.03	5.48E-11	2.34	1.10E-06	ATPase Na <sup>+</sup> /K <sup>+</sup> transporting subunit alpha 1
ATP1A2	1.68	2.88E-09	1.78	3.87E-09	ATPase Na <sup>+</sup> /K <sup>+</sup> transporting subunit alpha 2
ATP1A3	1.51	1.04E-01	1.23	4.59E-01	ATPase Na <sup>+</sup> /K <sup>+</sup> transporting subunit alpha 3
ATP1A4	1.50	6.86E-06	-2.13	8.05E-09	ATPase Na <sup>+</sup> /K <sup>+</sup> transporting subunit alpha 4
ATP1B1	1.46	1.07E-05	1.49	2.62E-05	ATPase Na <sup>+</sup> /K <sup>+</sup> transporting subunit beta 1
ATP1B2	1.45	3.69E-04	-4.98	5.63E-12	ATPase Na <sup>+</sup> /K <sup>+</sup> transporting subunit beta 2
ATP1B3	1.44	1.48E-02	1.16	3.51E-01	ATPase Na <sup>+</sup> /K <sup>+</sup> transporting subunit beta 3
ATP1B4	1.31	4.40E-05	1.76	1.37E-08	ATPase Na <sup>+</sup> /K <sup>+</sup> transporting family member beta 4
ATP2B1	1.30	6.82E-02	1.67	3.82E-03	ATPase plasma membrane Ca <sup>2+</sup> transporting 1
ATP2B2	1.27	9.89E-05	-1.07	2.17E-01	ATPase plasma membrane Ca <sup>2+</sup> transporting 2
ATP2B3	1.23	1.11E-01	-1.26	1.25E-01	ATPase plasma membrane Ca <sup>2+</sup> transporting 3
ATP2B4	1.21	5.16E-01	-1.19	5.92E-01	ATPase plasma membrane Ca <sup>2+</sup> transporting 4
CA1	1.16	2.01E-03	-1.54	5.39E-08	carbonic anhydrase 1
CA2	1.16	2.66E-02	1.29	2.15E-03	carbonic anhydrase 2
CFTR	1.13	5.94E-01	-1.47	1.39E-01	CF transmembrane conductance regulator
CLCN2	1.13	4.67E-01	-1.15	4.52E-01	chloride voltage-gated channel 2
CYBRD1	1.11	4.72E-02	-1.03	6.22E-01	cytochrome b reductase 1
HEPH	1.11	3.80E-02	-1.01	8.85E-01	hephaestin
KCNE3	1.10	4.57E-01	-1.44	1.66E-02	potassium voltage-gated channel subfamily E regulatory subunit 3
MAPK1	1.06	2.60E-01	1.11	6.59E-02	mitogen-activated protein kinase 1
MAPK3	1.02	9.25E-01	1.32	1.77E-01	mitogen-activated protein kinase 3
MKI67	-1.00	9.90E-01	-1.15	2.44E-01	marker of proliferation Ki-67
NFKB1	-1.01	9.24E-01	-1.62	6.07E-06	nuclear factor kappa B subunit 1
PLCG1	-1.07	3.50E-01	-1.31	4.87E-03	phospholipase C gamma 1
PRKCA	-1.08	4.43E-01	3.14	2.41E-08	protein kinase C alpha
SLC11A2	-1.10	4.96E-01	1.21	2.31E-01	solute carrier family 11 member 2
SLC12A2	-1.10	1.85E-01	-1.42	3.22E-04	solute carrier family 12 member 2

SLC26A3	-1.10	4.03E-01	-1.38	2.20E-02	solute carrier family 26 member 3

## CHAPTER 6

# General discussion

The urgency to obtain increased scientific knowledge in the field of gastrointestinal (GI) health is emphasized by the alarming fact that 40% of the worldwide population suffers from functional GI disorders (1). This not only results in an increase in global health care costs, but also in a decreased quality of life (1). Although gastric and esophageal disorders are all categories of GI disorders, in this thesis, we only focused on the intestine. Despite the advances in understanding intestinal health, still many underlying mechanisms remain elusive. In order to reduce the socioeconomic burden, it is of utmost important to increase our knowledge on intestinal health and the underlying mechanisms of intestinal pathophysiology. Only then, steps can be made towards reducing the prevalence of intestinal disorders on the one hand, and developing pharmacological or nutritional therapies to treat these diseases efficiently and effectively on the other hand. Therefore, the aim of this thesis was to investigate how multiple important aspects, including the aging process, gut microbiota, and bile acids, can affect intestinal health. To this end, we used physiologically relevant *in vivo* and *in vitro* models. In **Chapter 2**, we demonstrated that the aging process is associated with a pronounced change in gut microbiota composition and colonic gene expression, which are likely acting in concert to mediate colonic health during aging. We also observed a strong aging-related decrease in the abundance of the mucin-degrading bacterium *A. muciniphila*. In **Chapter 3**, we investigated the potential health-promoting effects of *A. muciniphila* by supplementing progeroid mice with this bacterium for 10 weeks. We found promising health-promoting effects of *A. muciniphila* with regard to the colonic mucus layer and immune-related processes. In both *in vivo* studies, the general dogma stating that aging-related microbial dysbiosis is related to impaired intestinal barrier function and intestinal inflammation is central. However, the molecular mechanisms underlying this negative feedback loop are not known. In this context, bacterial metabolites can act as key molecular mediators and are thus a highly relevant area of investigation. In **Chapter 4**, we investigated the role of sulfated BAs, which were previously shown to be elevated in IBD patients, on the progression of chronic intestinal inflammation. Although we found minor effects of sulfated secondary BAs on intestinal permeability, our evidence pointed towards that sulfated secondary BAs abolished the anti-inflammatory effects of secondary BAs when exposed directly to DCs. In *in vitro* research, the selection of a physiologically relevant model is a crucial aspect while designing a study. With regard to intestinal health, the mucus layer is often underrepresented in widely used models. To approach the intestinal barrier function in a more physiological way, we investigated the SWMS growing method to enhance mucus production in HT29-MTX-E12 cells in **Chapter 5**. This increased insight might ultimately lead to potential recommendations to further improve *in vitro* models to study intestinal health.

### A definition of intestinal health

Like anywhere in the body, it also applies to the intestine that homeostasis is a key aspect of health. Fundamental factors that are involved as determinants of intestinal health include a balanced microbiota composition, a well-functioning intestinal barrier, and the absence of inflammation, amongst others (2). Because of the intensive crosstalk between these factors, disturbance of one factor likely renders the others prone to disturbance as well. This vicious cycle is implied in a range of disorders and diseases of the intestinal tract, but also beyond. It is the strong involvement of the intestine in overall health that makes this a crucial area of investigation. However, before diving deeper into this research field, it is first important to discuss what intestinal health exactly involves. In 2011, a group of researchers determined five major criteria to define a healthy intestine. Some of these definitions are rather clear, such as *"An effective digestion and absorption of food"* and *"The absence of GI illness"* (3). However, other definitions could be interpreted in a less objective way. For example, the criterium *"A normal and stable microbiota"* might sound straightforward, but it is unclear what the scientific definition of 'normal' and 'stable' is. In the context of a healthy microbiota composition, 'dysbiosis' is a widely used and acknowledged term. Dysbiosis is often defined as the shift in microbial composition that is associated with pathology (4). More specifically, dysbiosis is considered as a change in resident bacteria relative to the gut microbiota of healthy individuals, including a loss of beneficial bacteria, an increase in potential pathobionts, and a decreased overall diversity (5). However, results from a recent study might question the generalizability of this definition towards all diseases. This meta-analysis showed that different diseases are associated with distinct types of dysbiosis (6). For example, the gut microbiota composition of colorectal cancer patients is characterized by an increase in pathobionts, while IBD patients are characterized by a predominant depletion of beneficial bacteria (6). Additionally, an important factor that should be taken into account is the influence of age on disease-associated dysbiosis. A recent study investigated the effect of age on the gut microbiota composition in five disorders: IBD, intestinal polyps, colorectal cancer, type 2 diabetes and liver cirrhosis (7). Age-specific trends in microbiota-disease associations were found, for example, younger subjects tended to gain disease-associated gut microbiota, while elderly subjects lost gut microbiota that are usually associated with health (7). The implication of age as a confounder emphasizes the importance to control for age to improve the robustness of microbiota studies. Altogether, it can be concluded that a more detailed description of disease-specific dysbiosis should be implemented with due consideration of potential confounders. Looking more carefully into intestinal dysbiosis is important, since a specific microbial profile could serve as determinant for predicting the manifestation of a disease or disorder (8). Ultimately, this approach could serve a

therapeutic goal by specifically targeting bacterial species, e.g. removal of harmful bacteria, and/or administration of beneficial bacteria, to eventually alleviate or cure intestinal disorders.

### Hallmarks of the aging intestinal tract

Over the last decades, extensive research has resulted in a substantially increased understanding in gut microbiota composition during health and disease, but also during different stages of life. The aging process is characterized by marked shifts in gut microbiota composition, which is associated with physical fitness and frailty (9, 10). On the contrary, it remains relatively unexplored how this microbial shift is induced and whether this is a cause or consequence of impaired health. However, it is unlikely that the causes are constrained by only a few factors, since a plethora of lifestyle, environmental and genetic factors might be involved. A central dogma states that diet has a dominating impact on shaping the gut microbiota composition (11). However, this dogma is rejected in a recent study showing that the influence of host physiology was substantially greater than dietary factors in primates (12). It was also shown that in *Drosophila*, the prevention of age-related changes in intestinal physiology limited microbial dysbiosis, and resulted in extended lifespan (13). Next to the influence of physiological factors, several drugs, such as antibiotics or proton pump inhibitors, could also lead to a microbial shift (14, 15). These findings might lead to the large heterogeneity in aging studies. Another important factor that might add to the high variety observed in gut microbiota composition in human subjects, is that the human gut microbiota can be classified in three different enterotypes, which are quite robust among different populations (16). However, the robustness, and even the existence of enterotypes is currently under debate (17). Nevertheless, the question rises whether a random group of healthy individuals is a valid control group for gut microbiota analysis, or that control groups should match the subjects of interest more closely with regard to e.g. lifestyle, diet, gender, and, potentially, enterotype. An important disadvantage of this strategy is the increased effort, and thus time and money, that are involved in the more extensive screening process to select eligible control subjects. The highly controlled environment that is maintained during animal studies (i.e. genetic background, diet and gender) eliminate a number of aforementioned factors. Furthermore, in the context of gut microbiota analysis, the use of animals allows the sampling of colonic luminal content, instead of the dependence on fecal samples that is most often the case in human studies. It is clear that the gut microbiota composition in fecal samples is different compared to luminal content (18). Indeed, in **Chapter 2**, we found differences between fecal and colonic microbiota composition, although these differences were subtle. Therefore, based on our results, fecal samples could still serve as reliable source to examine gut microbiota, at least in mice. However, when sampling luminal

content, it is important to consider the large diversity between different locations throughout the intestinal tract (19, 20). Newly developed techniques to sample luminal content, e.g. via catheter aspiration or other sampling devices (21), could be useful strategies to isolate luminal content from different parts of the intestine. These techniques are promising, especially with regard to sampling at different time points, which can be very useful to study time-dependent effects of gut microbiota composition. However, there are also challenges to overcome, for example to successfully sample the relatively firm colonic content, but also to preserve the intestinal sample (22).

### From an observational to a functional approach

The complexity of the gut microbiota is also emphasized by the fact that a repertoire of bacterial species residing in the intestine remains to be discovered (23). Indeed, in **Chapter 2**, we detected a considerable number of undefined species, limiting us to fully specify bacteria at the species level. Instead, we were restricted to define some present bacteria at genus or even family or order level, which might have led to a less complete interpretation of the data, given the high variety of bacteria with different functions within taxa. In the future, this limitation will most probably become less prevalent, as the rapid development of high-throughput sequencing techniques facilitates the characterization of newly discovered species (23). Nevertheless, the question rises whether it would be more appropriate to shift our focus from the observational approach (*"Who is present?"*) to a more functional approach (*"What do they do?"* and *"How do they do it?"*). One possible approach in this regard is to investigate the presence of bacterial metabolites, as these could have important effects on intestinal barrier function and mucosal immune response, and are therefore considered as the communicating factor between the microbe and host (24). Importantly, profiling shifts in bacterial metabolites is the first step towards the transition from observational studies to studies investigating cause-and-effect relationships of specific bacterial metabolites and their effect on (impaired) intestinal health. In **Chapter 2**, we determined age-related shifts in metabolites present in colonic luminal content using <sup>1</sup>H-NMR. It is noteworthy to mention that the metabolites present in colonic luminal content are not by definition derived from the gut microbiota, but can also be derived from food or host cell metabolism. In **Chapter 2**, we aimed to get clues on the origin of metabolites in colonic luminal content. Therefore, we correlated the levels of significantly altered metabolites to the relative abundances of the most present genera. These results could serve as starting point for future studies investigating the causal effects of these bacteria-derived metabolites on markers of intestinal health. However, instead of just correlation analyses, more sophisticated methods exist that can fully profile the function of the present bacterial communities by sequencing the complete

microbial genome present in a sample. This shotgun metagenomics approach opens new and promising avenues in, amongst others, unraveling complex host-microbe interactions (25). Despite the technical breakthrough, an important limitation of this next-generation sequencing method is the high costs (25). However, the high demand for this technique already led to a rapid decline in the costs. In addition to the taxonomic approach that we performed in **Chapter 2**, a metagenomic approach would also have been useful for this study. Instead, we focused on multivariate methods to integrate transcriptomic and microbiome data to find clues about the interactions between bacteria and host in the vicinity of the colonic wall. For example, we found that the strong downregulation of genes encoding for AMPs at old age was positively correlated with an uncultured member of the order *Gastranaerophilales*. A plausible hypothesis would be that the decreased relative abundance of this bacterium could be related to an impaired intestinal barrier function by causing a downregulation of AMPs during aging. However, it is important to realize that multivariate- and metagenomic analyses do not provide information about the bacterial products that are ultimately present. In this regard, the use of metabolomic analysis is highly important.

#### **Lessons from extreme longevity studies: the case of *Akkermansia muciniphila***

As important mediator of intestinal health, gut microbiota composition is proposed to be a highly relevant candidate to manipulate as a strategy to improve healthy aging. However, it is first important to obtain insight in the bacterial species that are involved in healthy aging. To this end, a highly relevant study population include subjects with extreme longevity, i.e. centenarians; people older than 100 years. These subjects are reported to reach this extreme age with lower incidence of chronic diseases (26), and lower hospitalization rates (27), as compared to younger subjects. The analysis of the gut microbiota composition in centenarians could therefore provide extremely useful information about specific bacterial species that might be related to reaching an extremely high age in a healthy way. Although it remains unknown whether the gut microbiota composition is causal or rather a consequence of the lifestyle of these subjects, it will still provide useful information that can be used for future studies. In this sense, a key example of a 'centenarian-enriched' species is *A. muciniphila*, which was found to be increased in centenarians (28-30). In mice, the abundance of this bacterium was shown to be negatively correlated with inflammation, glucose intolerance and insulin resistance (31, 32). In humans, negative correlations were also found between *A. muciniphila* and both overweight and obesity, as well as markers of insulin resistance and hypertension (33-35). These associative studies provide a solid base to proceed to the next step: performing proof-of-concept studies to determine a potential causal link. In **Chapter 3**, we showed that supplementing progeroid

mice with *A. muciniphila* resulted in, amongst others, attenuation of inflammation, suggesting that supplementation could be an effective strategy to improve inflammaging. The beneficial effects of this bacterium were also proven in humans. Although this study focused specifically on metabolic effects rather than the aging process, three months of *A. muciniphila* supplementation improved metabolic and inflammatory parameters in obese and insulin-resistant human subjects (36). The same study also confirmed the safety and tolerance of supplementation in humans (36). Altogether, these data open avenues for the application of *A. muciniphila* supplementation as a strategy to improve health. Interestingly, supplementation with pasteurized *A. muciniphila* was also shown to be effective in mice (37, 38) and humans (36). The use of pasteurized bacteria improves the applicability of supplementation, as the use of live bacteria may pose difficulties with regard to shelf life and viability, and thus the degree of efficacy. Moreover, pasteurized *A. muciniphila* was recently shown to be safe as a food ingredient (39). It is clear that *A. muciniphila* supplementation is a potent strategy to improve health, however, until now, all studies mainly focused on obese/overweight, middle-aged subjects that suffer from metabolic disease. Although this study population can be generally considered as metabolically unhealthy, it is impossible to directly translate the effectiveness, safety and tolerability of *A. muciniphila* supplementation of these subjects into elderly subjects. This issue even applies more when taking into account frail elderly. Although speculative, it might be possible that the GI tract and immune system of (frail) elderly is less able to cope with a bulk of bacteria, which may result in adverse health effects, instead of the intended beneficial effects (40). In a parallel arm of the study described in **Chapter 3**, supplementation with the probiotic bacterium *Bifidobacterium breve* had adverse effects on mucus layer thickness and immune function in progeroid mice (41). With regard to *A. muciniphila*, there is evidence that the presence of this bacterium during *Salmonella typhimurium* infection exacerbates inflammation (42). A lower number of goblet cells was found, together with a loss of mucin sulphation, indicating that *A. muciniphila* caused disturbance of mucus homeostasis (42). The ability of *A. muciniphila* acting as a pathobiont emphasizes that probiotic supplementation of this bacterium in persons with underlying (inflammatory) diseases, e.g. frail elderly, should be considered with great awareness. Another important field of investigation is to determine the most effective mode of administration for elderly persons. For example, oral administration via a capsule may be less suitable for elderly compared to fluidic supplementation, which is more easy to swallow. Altogether, although the use of *A. muciniphila* supplementation is a promising therapeutic strategy to improve health, the effectiveness and applicability in elderly subjects should be carefully investigated in future studies.

**Metabolomics and metagenomics as tools to understand healthy aging**

The relevance of discovering centenarian-specific signature species and consider these as biomarkers for healthy aging could also be debated. First, just like in any other population, high variation is observed in centenarians as well. This could lead to misinterpretation of results, ultimately leading to incorrect assignment of species to be centenarian-specific. For example, a Chinese study showed that *A. muciniphila* abundance was declined in centenarians (43), which might hamper the general consideration that this bacterium is centenarian-specific. Although this single study is unlikely to question the plethora of other studies confirming the effectiveness of *A. muciniphila* supplementation, interindividual variation could pose difficulties in interpreting results regarding other bacterial species yet to be discovered. One way to overcome this issue is to focus more on potential confounders, such as diet, living situation, and geographical location, amongst others, as these factors are known to have a profound effect on gut microbiota composition (44). Secondly, in the process of using centenarian-enriched species as a strategy to improve healthy aging, one crucial aspect is often neglected; i.e. the underlying mechanism through which the bacterium exerts the beneficial health effects. In this sense, not necessarily the presence of certain bacteria is important, but rather the function of these bacteria. To this end, bacterial metabolite analysis might provide useful information. In a large cohort study, it was shown that healthy aging was characterized by a unique gut microbiota composition, which was reflected by a distinct plasma metabolite profile (45). On the other hand, the use of metagenomic sequencing methods in elderly or centenarian subjects could provide useful information about the pathways through which the present microbiota exert their health-related effects. For example, shotgun metagenomics of fecal microbiota in an Italian cohort revealed an age-related increase in reads for genes related to xenobiotic degradation, which was even stronger in centenarians and supercentenarians (aged 104-109 years) (46). It is noteworthy to mention that this functionality was assigned to commensal bacteria that belong to the more general human core microbiome (46). The authors speculated that this observation was due to an adaptive response of the gut microbiota to the increased exposure to xenobiotics in these long-lived subjects. Exposure to xenobiotics is related to an increased risk of autoimmune disease and cancer (47, 48), but also to intestinal diseases (49). Therefore, an increased capacity of the gut microbiota to degrade xenobiotics might therefore be considered as a health-promoting microbial shift, particularly with regard to the aging process, as accumulation of xenobiotics may occur in long-lived people. Hence, the performance of studies in this field of 'toxicomicrobiomics' is relevant particularly with regard to the aging process.

### Disentangling the mechanisms underlying healthy aging through probiotics

Given the fact that the influence of host physiology plays a major role in shaping gut microbiota composition (12, 13), it could be speculated that prevention of age-related changes in intestinal physiology is a useful target to improve intestinal health, instead of, for example, focus on dietary strategies. On the other hand, this approach also poses limitations. For example, techniques to determine changes in human intestinal physiology might be challenging due to technical or ethical concerns, especially in elderly. Moreover, not all bacterial species rely on nutrients derived from the food ingested by the host, but rather on alternative sources that are independent of diet. A good example includes the group of mucin-metabolizing bacteria that reside in the mucus layer and degrade mucin glycans, such as strains within the genera *Bacteroides*, *Ruminococcus*, *Bifidobacterium* and *Akkermansia* (50). This, together with the observation that the colonic mucus layer decreases with age in mice (41, 51, 52) emphasizes the importance of investigating both the colonic mucus layer and mucin-degrading bacteria in the context of healthy aging. Unfortunately, current available data is mostly restricted to animal studies, which is most probably due to the practical issues of successfully isolating mucus *in vivo*. Nevertheless, an especially important candidate to manipulate the colonic mucus layer is *A. muciniphila*. In **Chapter 3**, the observed attenuated inflammation and immune-related processes in mice supplemented with *A. muciniphila* might be the result of a reinforced mucus layer induced by this bacterium, as this is a crucial factor for a strong intestinal barrier that keeps potential health-disturbing compounds at bay. However, our study design was not suitable to establish if this role was indeed causative. Therefore, a highly relevant and fundamental issue would be the mechanism underlying the increased mucus layer thickness induced by *A. muciniphila*. The combined mucin-degrading and mucus-building capacities of this bacterium seem contradictory, although both properties are well-established (53-55). With regard to the mucus layer, another question that rises is what the effect *A. muciniphila* on mucus quality would be, i.e. the effects on firmness and stability of the mucus layer, but also the presence and accessibility of glycans, amongst others. Unraveling these mechanisms is important to be able to comprehend the health-promoting effects of *A. muciniphila* and perhaps even to (pharmacologically) target the mucus layer without the use of this mucus-promoting bacterium. This could be promising, especially with regard to susceptible elderly. Although the use of commonly used probiotics is generally safe, application in (extremely) frail elderly might pose a potential risk if side effects occur. A more direct way to target the mucus layer by using drugs that act through the same mechanism as *A. muciniphila* might be a solution to prevent these probiotic-induced side effects.

### **Dysbiosis as common denominator for aging and IBD**

The existence of dysbiosis during the aging process is clear. Dysbiosis is also heavily involved in the pathogenesis of IBD (56). Obviously, fundamental differences exist in pathways involved in the aging process and IBD pathology, however, a remarkable resemblance in dysbiosis is found, characterized by a loss of health-associated species (6). This could imply that therapeutic interventions aimed to restore these beneficial species, e.g. pre- and probiotic use, might be a useful treatment for both aging- and IBD-specific dysbiosis. Speculatively, the similarity in dysbiosis might also lead to a similar shift in bacterial metabolite production. However, this speculation requires more insight in specific bacterial species and the metabolites produced. In **Chapter 2**, we found a significant decrease in an unspecified bile acid in old mice. Although our method was not sensitive enough to profile this BA more specifically, it could be ruled out that it is one of the BAs identified in our previous study (57), i.e. cholic acid, (tauro)deoxycholic acid, or chenodeoxycholic acid. In a recent study, an increased ratio of primary to secondary BAs was found in colonic content of both male and female mice, which was concomitant with a decreased relative abundance of bacteria associated with BA deconjugation and 7-dehydroxylation (58). A decreased abundance of these bacteria, and thus decreased enzymatic activity, could have led to the observed decrease in secondary BAs. Moreover, a decreased relative abundance of *Peptococcus* was found in old female mice, which is a genus involved in BA desulfation (59). Although the amount of sulfated BAs was not measured, an impaired desulfation capacity may have led to an increase in sulfated BAs, which was found to be a consequence of a dysbiosis-related decrease in enzymatic activity in IBD patients (60). Interestingly, after co-housing with young mice, both the primary to secondary BA ratio and relative abundance of *Peptococcus* restored again to a similar extent to that of young mice (58). These results highlight the potential similarities in dysbiosis, and consequently, shifts in bacterial metabolites between the aging process and IBD. However, much more research is needed to understand the fundamentals of BA-driven disease progression. In this regard, data from observational studies could serve as starting point to studies investigating the causal relationships.

### **Secondary bile acids as drivers or preventers of intestinal inflammation: sulfation feeds the controversy**

The implication of BAs on disease progression has been subject to controversy, given the contrasting results found in several studies investigating BAs. For example, secondary BAs have been shown to cause higher intestinal permeability in Caco-2 cells (61, 62) and in mice (63). Furthermore, secondary BAs were also related to higher colon cancer incidence (64, 65). On the other hand, secondary BAs

were shown to have anti-inflammatory properties in mice (66, 67) and *in vitro* studies (60, 68). These contradictive results could indicate that the effects of BAs are context-dependent, for example the concentration and type of BA, and the tissue where the BAs are present. In the case of secondary BAs, multiple subtypes are present in the body, for example secondary BAs conjugated with taurine, glycine or sulfate-groups (69, 70). However, these conjugated secondary BA are less prevalent compared to their unconjugated form, which might be a plausible cause of the relatively low amount of studies performed on their potential health effects. In the context of the aforementioned dysbiosis-related decrease in enzymatic activity in IBD patients (60), we aimed to investigate the causal role of sulfated secondary BAs on IBD progression in **Chapter 4**. The choice to investigate this type of BA may add to the general BA controversy, since it is generally accepted that sulfation is a process to detoxify and eliminate the normally cytotoxic secondary BAs (71). Therefore, the hypothesized involvement of sulfated BAs in IBD progression might sound counterintuitive, which is emphasized by the fact that only a low amount of studies have been published on the role of sulfated BAs in any disease. The literature that is available is often dated, as most studies are published over 40 years ago. The first matter of debate is the question whether sulfated BAs are absorbed by the intestinal cells, due to their hydrophilic character. In **Chapter 4**, we found that expression of FXR-target genes in intestinal cells was not altered after exposure to sulfated LCA and sulfated DCA, indicating that these BAs are most probably not taken up by the cells to activate FXR. On the other hand, sulfated BAs may possibly activate TGR5, since this is a membrane-bound BA receptor and might therefore be activated without intracellular uptake of the ligand. Unfortunately, we were not able to measure TGR5 activity. It would have been worthwhile to investigate this, for example by a luciferase reporter assay or by measuring intracellular cAMP levels, which is induced by TGR5 (72). This is particularly important, since several studies showed that TGR5 is implicated in, amongst others, intestinal barrier integrity (73) and regeneration of injured intestinal tissue in intestinal stem cells (74). Moreover, TGR5 is also implicated in immune response, since this receptor is expressed on immune cells (68), and both natural TGR5 agonists (DCA and LCA) as well as a synthetic TGR5 agonist suppressed TNF- $\alpha$  production in macrophages via the TGR5-cAMP pathway (75). Potentially, IL-10 plays an important role, since TGR5 was shown to regulate *IL-10* gene expression in a macrophage cell line (76). Although sulfated BAs had only minor effects on intestinal barrier function in **Chapter 4**, our results pointed towards an abolishment of anti-inflammatory effects exerted by secondary BAs. Future studies should focus on molecular pathways underlying these effects and the implication on IBD progression. Furthermore, a more detailed exploration of the effects on the mucus layer would also be highly relevant, given the important role of the mucus layer in intestinal health. In **Chapter**

4, we only investigated the expression of *MUC2* and *MUC5AC*, while examination of other relevant parameters regarding mucus quantity and quality will provide more complete information. However, with regard to in-depth investigation of the mucus layer, more effort should first be made towards the establishment of relevant and reproducible techniques.

### Challenges of investigating the mucus layer

Although it is clear that the mucus layer plays an extremely important role in health and disease, obtaining mechanistic insight is not straightforward. For example, mucins are extremely big proteins (*MUC2* is 540 kDa) and are subject to complex post-transcriptional modifications (77, 78). Moreover, isolation of the mucus layer also faces some technical challenges. For example, mucus is transparent and has a high water content, which makes isolation and preservation of the mucus layer challenging and therefore requires specialized expertise (79). Where other aspects of the intestinal barrier are relatively easily performed, i.e. a FITC-dextran assay to measure intestinal permeability, suchlike assays to investigate the mucus layer *in vivo* are not widely described yet. Currently, animal models are commonly used, that allow the collection of intestinal tissue and analysis of the mucus layer upon sacrifice. In **Chapter 3**, we used histological techniques, including a Carnoy fixation of intestinal tissue to preserve the mucus layer, and subsequently a PAS/Alcian blue to stain mucins. The dependency on intestinal tissue to investigate mucus poses an important disadvantage, since it is not possible to measure the mucus layer *in vivo* at different time points. The relevance of time-dependent mucus measurements is important given the fact that the mucus layer thickness is highly dynamic (80). Consequently, a single measurement could lead to incomplete or false interpretations. Alternatively, it is possible to isolate mucus derived from colonic biopsies and determine the mucus quality in an *ex vivo* manner, as described previously in IBD patients (79). This study indicates that it is possible to isolate mucus samples in humans, however, the feasibility remains doubtful due to the invasiveness of taking a biopsy. Furthermore, it could be questionable whether the use of *ex vivo* techniques to investigate mucus characteristics are completely representative for the *in vivo* the mucus layer, or if, for example, the composition of isolated mucus changes once outside the body. Importantly, as an increasing number of studies are focusing on the involvement of the mucus layer in health and disease, it is of utmost importance to establish methods to successfully isolate mucus *in vivo*, preferably in a non-invasive manner. Although speculative, a potential direction in this regard could be the use of biomarkers to assess mucus quantity and/or quality. Mucus is excreted via feces, implicating that mucus can be directly isolated from feces. Indeed, mucus isolation from feces was described in a previous study, although the authors aimed to examine colonocyte numbers

present in mucus instead of investigating mucus properties (81). Subsequent methods to assess mucus quantity could be to measure total mucin content, for example by an Alcian Blue Mucin Assay (82). Besides, measuring other factors present in mucus that are indispensable for a strong mucus layer might also provide useful information on mucus quality. Obviously, the usefulness of these potential novel measurements should be investigated and optimized carefully before it can be applied in studies.

### **Modeling the *in vitro* mucus layer: from static to dynamic conditions**

Since *in vivo* methods to investigate the mucus layer are to be optimized and *ex vivo* techniques also require specialized equipment and expertise, *in vitro* models still remain a useful alternative to investigate mucus properties. However, in commonly used *in vitro* models representing the intestine, the mucus layer is often overlooked, and if present, poorly representative. For example, frequently used colonic cell lines, including Caco-2 and T84 cells, produce only a limited amount of gel-forming mucins, which makes them irrelevant when used as a mono-culture. When grown in a co-culture with a mucus-producing cell line, e.g. HT29-MTX, the representativeness is slightly improved. However, important disadvantages of HT29-MTX cells is that, when grown statically, only a thin mucus layer is secreted, which predominantly exists of MUC5AC, which is a mucin typically present in the stomach and lungs (83). The intestinal MUC2 is also present, but to a lesser extent (84). An important factor that impedes the *in vitro* translatability of the *in vivo* situation is that current *in vitro* models are often static, while in the *in vivo* situation is highly dynamic. To overcome this, Navabi and colleagues established the semi-wet interface with mechanical stimulation (SWMS) method that resulted in a thick and adherent mucus layer, which predominantly consisted of MUC2 (84). In **Chapter 5**, we confirmed that the SWMS method indeed resulted in a shift in mucin composition, i.e. a higher MUC2/MUC5AC ratio. However, the exact mechanisms by which the SWMS method resulted in increased mucus production remain elusive. The aim in **Chapter 5** was to improve our understanding in the underlying mechanisms, which could ultimately help to improve the representativeness of the *in vitro* mucus layer. We found that SWMS culture conditions resulted in increased cell growth and a shift towards a more aerobic cell metabolism, which might be the driving factors behind the increased mucus production. With regard to the implications for SWMS methods in current *in vitro* cell culture models, the obvious question that rises is if this method indeed results in an improved model. Based on our findings, the SWMS method can indeed result in an improved mucus layer with regard to the mucin composition. Therefore, if a model is needed that only requires the presence of a mucus layer, e.g. drug-disposition studies or the exposure of bacterial metabolites, the SWMS

method is a relatively simple yet effective strategy. In **Chapter 4**, we deemed the SWMS method suitable to apply in our study design, since we aimed to establish a physiological relevant *in vitro* model representing the inflammatory situation as observed during IBD. As first line of defence, the mucus layer is indispensable for intestinal barrier function and is therefore crucial to include in an IBD model. By using activated DCs to create a pro-inflammatory environment, we hypothesized that both the mucus layer and intestinal epithelial cell layer were negatively affected. Indeed, we found a significantly increased intestinal permeability of the monolayer. In addition, we found a strong decreased expression of *MUC2* and *MUC5AC* in intestinal cells exposed to activated DCs compared to unexposed control cells. However, we did not dive deeper into mucus properties, as we were unable to isolate the mucus layer from the cell culture inserts.

In mucus research, not only the mucus quantity is important, but also the mucus quality. Although the determinants of mucus quantity are sufficiently established (e.g. mucus layer thickness and mucin content), some methods to measure mucus quality are described, however, these methods are not widely used yet. An explanation for this could be similar to the aforementioned example, i.e. the specialized expertise needed to perform such methods. A relevant method with regard to mucus quality is to measure mucus penetrability using fluorescent beads that have a similar size as bacteria. This method, described by Gustafsson et al. (80), provides useful information on an important functional property of mucus, i.e. the capacity to avoid penetration of bacteria into the mucus layer. Until now, this method is only described using tissue explants grown *ex vivo* on a perfusion chamber (80). It would be highly relevant if suchlike methods could be applied in *in vitro* settings as well. In **Chapter 5**, we attempted to use this method on HT29-MTX-E12 cells grown on Transwell membranes. Although the preliminary outcomes seemed promising, we were unable to further optimize this protocol, due to time constraints and practical issues regarding laboratory equipment. Therefore, we considered the data not fully complete to be included in this chapter.

If the mucus layer should play a more central role in the model, e.g. in studies investigating the effects of specific compounds on mucus quality and quantity, the SWMS method might not be the best method. In this case, more relevant options include the use of *ex vivo* derived mucus (79), or the use of organoid or gut-on-a-chip models (82, 85), amongst others. Importantly, when using these more sophisticated models, researchers should not take for granted that the mucus layer is automatically representative. Instead, the mucus layer should be carefully investigated with regard to thickness, evenness, stability and composition. Furthermore, it should be taken into account that often extensive study set-ups are needed to achieve sufficient mucus yield to be able to perform quantity and quality assays. Importantly, the significance of the mucus layer in health and disease

requires more scientific interest and therefore more research should be carried out to be able to investigate the mucus layer into more detail. For example, these models can be used to investigate the influence of dietary or microbial components on mucus properties. Eventually, these models could also be relevant to investigate the potential of (newly discovered) therapeutic interventions.

### The importance of approaching intestinal health from different perspectives

The role of the intestine in a plethora of diseases and disorders emphasizes that intestinal health reaches much further than the intestinal tract alone. Increased scientific insight in underlying mechanisms is therefore crucial to keep the intestine in a healthy condition. In this thesis, we took a multiperspective approach to investigate intestinal health by focusing on the aging process, gut microbiota and bile acids. As schematically depicted in Figure 1, an intricate relationship exists between these factors.

**Figure 1** A schematic overview of the interplay between parameters of intestinal health: intestinal barrier function, gut microbiota composition, bacterial metabolites and inflammation. In this thesis, we investigated the effects of the aging process on these aspects and evaluated the use of the probiotic *Akkermansia muciniphila* to improve intestinal health during the aging process. We also investigated the effect of bacterial metabolites (bile acids) on intestinal barrier function in the context of inflammatory bowel disease (IBD).

Intervening in these processes, for example by bacterial supplementation (e.g. *A. muciniphila*) might be a promising strategy to improve intestinal health. Importantly, investigation into the role of bacterial

metabolites (e.g. bile acids) is crucial to understand the consequences of the gut microbiota during health and disease, such as IBD. *In vitro* models described in this thesis might be relevant for future research that aims to investigate the role of bacterial metabolites in intestinal health.

# Summary

It is widely acknowledged that the intestine plays an essential role in the maintenance of overall health. A well-regulated balance exists in the intestine, where on the one hand the uptake of nutrients is ensured, and on the other hand the entrance of bacteria and potentially harmful compounds is restricted. The intestinal barrier is responsible to carry out these highly important, but complex tasks. The intestinal barrier include the mucus layer, the intestinal epithelial cell layer and the immune cell 'layer. In a healthy condition, the trillions of micro-organisms that are present in the intestinal tract have a beneficial relationship with the host. However, in case these highly regulated processes are impaired, the risk of (intestinal) diseases increases. As the prevalence of intestinal disorders is increasing worldwide, there is a high urgency to increase the scientific knowledge in the field of intestinal health. The aim of this thesis was to investigate the effects of relevant aspects that are known to be involved in intestinal health: the aging process, gut microbiota, and bile acids. To investigate this, we used relevant *in vivo* and *in vitro* models.

The life-expectancy of humans has increased over the past centuries. However, the aging process increases the risk of disease, including intestinal disorders. To improve healthy aging, it is important to gain insight in the mechanisms underlying aging-related impaired intestinal health. In **Chapter 2**, we investigated the effects of the aging process on different aspects of intestinal health using C57BL/6J mice aged 6, 12, 24 and 28 months. We found pronounced changes in gut microbiota composition during aging, including an enrichment of potential pathobionts and a decline in health-promoting bacteria, such as *Akkermansia* spp. Transcriptome analysis of colonic scrapings pointed towards a decreased intestinal immune response during aging. To explore interactions between the gut microbiota and host colonic gene expression, a comprehensive integrative analysis was performed. The observed correlations between specific bacterial genera and host gene expression may serve as a starting point for future studies investigating the exact host-microbe interactions that take place in the vicinity of the colonic wall.

Since a detrimental shift in gut microbiota composition is frequently observed during aging, manipulation of the gut microbiota in the aged population could be a strategy to enhance healthy aging. A highly promising candidate is *Akkermansia muciniphila*, since a wide range of studies showed that this bacterium has beneficial effects on low-grade inflammation and (cardio)metabolic disorders. However, the effects of *A. muciniphila* on intestinal health parameters are not widely investigated yet. In **Chapter 3**, we supplemented progeroid *Ercc1<sup>Δ-17</sup>* mice with *A. muciniphila* for 10 weeks and investigated histological, transcriptional and immunological aspects of intestinal health. We found that the thickness of the colonic mucus layer increased about 3-fold in supplemented mice compared to the control group that did not receive supplementation. Moreover, both transcriptomic

and immunological analysis revealed an improved immune status. These results highlight the potential anti-inflammatory properties of *A. muciniphila*, which serve as a starting point for future studies investigating the use of this bacterium as a therapeutic intervention in the elderly population.

The involvement of the gut microbiota in inflammatory disorders of the intestine, such as IBD, is widely acknowledged. Bacterial metabolites, which are the end products of bacterial metabolism, have a great influence on intestinal health, such as immune response and intestinal barrier function. Therefore, the shift in bacterial metabolite composition as a result of IBD-related dysbiosis could play a role in IBD pathology. In a previous study, increased levels of sulfated BAs were found in IBD patients, but the exact effect of sulfated BAs on disease progression has not been investigated yet. In **Chapter 4**, we aimed to investigate the effects of sulfated secondary bile acids on intestinal barrier function and immune response. We first established a novel inflammatory *in vitro* human intestinal model which was exposed to sulfated deoxycholic acid (DCA), sulfated lithocholic acid (LCA) and their unsulfated forms. Sulfated BAs had a minor effect on intestinal barrier function. In line with previous studies, we found evidence that pointed towards anti-inflammatory effects of LCA and DCA. However, these effects were not observed for sulfated LCA and DCA. These findings might imply that impaired metabolism of BAs is involved in IBD progression.

In commonly used *in vitro* models used to investigate intestinal health, the mucus layer is often overlooked or underrepresented. However, the mucus layer is a highly important with regard to intestinal barrier function. To this end, it is highly important to improve the physiologically representativeness of *in vitro* intestinal models, for example by applying special culturing strategies. A previous study described a semi-wet interface with mechanical stimulation (SWMS) method to increase mucus production in the mucus-producing cell line HT29-MTX-E12. In **Chapter 5**, we aimed to investigate the underlying (molecular) mechanisms of this method. We found that SWMS culture conditions resulted in increased cell growth and a shift towards a more aerobic cell metabolism, which might be the driving factors behind the increased mucus production. This SWMS culturing method might be a simple, yet effective strategy to apply in *in vitro* intestinal models that require the presence of a mucus layer, e.g. studies investigating drug-disposition or the exposure of bacterial metabolites. In order to improve the physiological representativeness of the mucus layer even more, further research should focus on the qualitative aspects of the *in vitro* mucus layer.

In this thesis we investigated intestinal health from different perspectives. We focused on the effects of the aging process, gut microbiota and bile acids on important intestinal health parameters. We showed that the aging process has profound effects on gut microbiota composition and that supplementation with *Akkermansia muciniphila* might be a potential strategy to improve healthy

aging. Besides, bacterial metabolites, such as secondary bile acids, play a crucial role in intestinal health and disease. Although the studies presented in this thesis contribute to our understanding with regard to intestinal health, still much remains to discover. An important aspect of future research on intestinal health should be to focus on the exact underlying mechanisms. To this end, the *in vitro* intestinal model described in this thesis could be a useful model. Ultimately, increased knowledge of intestinal health will contribute to the development of therapeutic strategies to treat, or even prevent intestinal disorders.

# Acknowledgements

## Dankwoord

Eindelijk is het dan zover, het allerlaatste onderdeel van dit proefschrift! En natuurlijk kan geen enkel proefschrift zonder dankwoord. Aan het einde van mijn PhD realiseer ik me nog maar eens extra wat een leuke en lieve mensen ik tot mijn collega's, vriendenkring en familie mag rekenen. Dank allemaal voor jullie bijdrage aan de leuke momenten tijdens de afgelopen jaren!

Ten eerste wil ik graag **Wilma** bedanken. Wij gaan al best een tijdje mee samen! Jij hebt me begeleid tijdens mijn MSc thesis, Research Master Track, stage en vervolgens natuurlijk tijdens mijn PhD. Ik heb de afgelopen jaren enorm veel van je geleerd en daar ben ik je heel dankbaar voor. Je bent altijd scherp, snel van begrip, oplossingsgericht en behulpzaam. Onze vele overleggen samen waren altijd gezellig, soms zelfs zo gezellig dat de tijd al bijna voorbij was voordat we het over ook maar iets wetenschappelijks hadden gehad. Maar altijd liep ik weer vol inspiratie en motivatie je kantoor uit. Bedankt dat ik altijd op je kon rekenen!

**Sander**, je hebt me regelmatig de sturing gegeven die ik op dat moment nodig had om mijn onderzoek een stap verder te brengen. Als geen ander beheers je de kunst om de juiste vragen te stellen die meer dan eens leiden tot interessante inzichten. Dank voor al je hulp de afgelopen jaren!

I would also like to thank **Jerry Wells**, **Jan Knol**, **Paul de Vos** and **Hans Bouwmeester** for their willingness to be part of my committee. Thank you for critically reviewing and judging my PhD thesis.

**Merel**, ik vind het zo leuk dat wij elkaars paranimfen zijn! Heel erg bedankt dat jij als paranimf aan mijn zijde wilt staan. Jij staat echt altijd voor iedereen klaar en met je docentenskills kan je alles ook nog eens heel goed uitleggen. Ik ben je enorm dankbaar voor de vele labtechnieken die je mij door de jaren heen hebt geleerd. Het is alleen wel verstandiger om ons samen niet meer te wagen aan 'moeilijke' berekeningen, want dat gaat gegarandeerd mis ;-). De ontelbare koffie-haalmomentjes, wandelingen, spelletjesavonden, borrels en barbecues waren onvergetelijk. Uiteraard kan ik **Ingmar** dan ook niet vergeten te bedanken! Jullie kwaliteiten om feestjes te organiseren zijn echt onvoorstelbaar goed. Of het nou om een trouwfeest, verjaardag of voetbal/fiets-kijkavond gaat, het ontbrak werkelijk nooit aan iets! Het is fantastisch om ongeveer bij elkaar in de achtertuin te wonen, laten we nog heel veel gezellige momenten beleven met z'n allen, inclusief **Tristan**!

**Janneke**, wat een toeval dat wij een aantal jaren geleden bij elkaar gebracht zijn door onze gemeenschappelijke interesse: mucus. En wat blijkt, de sticky eigenschappen van mucus hebben

ervoor gezorgd dat wij sindsdien bij elkaar zijn blijven plakken! Het bleek namelijk niet onze enige overeenkomst, en van mucusmaatjes werden we al snel framemaatjes. Tijdens de duizenden kilometers die wij samen op de fiets hebben doorgebracht, kwamen we vaak achter nóg meer gemeenschappelijke interesses. Dit resulteert nog steeds regelmatig in het feit dat ik na afloop van onze fietsritjes vaak vermoeider ben van het kletsen dan van het fietsen zelf. Ik bewonder je tomeloze energie en inzet, je rotsvaste vertrouwen dat er een Elfstedentocht aankomt en uiteraard je onophoudelijke stroom aan woordgrappen. Ik vind het super dat jij mij wilt bijstaan als paranimf, heel erg bedankt daarvoor!

Daarnaast wil ik graag al mijn (oud)-collega's bedanken! **Xanthe** en **Mara**, wij gaan al terug tot onze Masters! Samen stortten wij ons in het avontuur van de RMT en begonnen daarna (ongeveer) gelijktijdig aan onze PhDs. Het was ontzettend fijn om deze tijd samen met jullie mee te maken en wat hebben we een leuke momenten beleefd! Xanthe, ons tripje naar Barcelona (incl. onze dagelijkse patatas bravas) zal ik nooit vergeten. Net zoals onze imitaties van internetgekkies en slappe lach over Xasse en Besse ;-). Mara, nog een darm-partner in crime! Dankjewel dat ik altijd met jou kon sparren over darm-vraagstukken! Onze wandelingetjes, borrels, barbecues of 'walking dinners' waren altijd super gezellig. Hopelijk gaan we nog vaak samen herinneringen ophalen met z'n allen! **Charlotte**, ook wij hebben ontelbaar veel gezellige momenten beleefd tijdens borrels, etentjes, 5 mei-feestjes, nog meer borrels, enzovoorts. Ongetwijfeld gaan er nog veel meer volgen, ik kijk er nu al naar uit! En uiteraard heel erg bedankt voor je hulp met alle vragen die ik had over het in elkaar zetten van dit boekje ;-). **Danny**, I always enjoyed our conversations about the differences between China and the Netherlands. I really admire the way you adapted so quickly to the Dutch culture. If you want to have more tips on sightseeing in the Netherlands, you can always contact me! **Anouk, Brecht, Frank** (speciale dank voor het bijbrengen van de fijne kneepjes van het DC-vak), **Lisa, Miranda, Monique, Montse, Tessa, Xiaolin, Philip, Antwi, Susanne** en **Shauna** ontzettend bedankt/thank you all voor alle gezelligheid op werk, op het lab en natuurlijk tijdens de lunch, picknicks en borrels!

**Karin**, het was altijd gezellig om met je te kletsen op werk of in de moestuin (tijdens het meditatief onkruidwieden). De jaarlijkse tomatenplanten en moestuinoogst heb ik altijd zeer gewaardeerd! **Mechteld**, nog een fietsende collega! Dankjewel dat je altijd voor me klaarstond om te helpen tijdens mijn experimenten. Het was niet alleen gezellig met je op het lab, maar ook op de mountainbike of racefiets! Ik hoop dat we nog veel ritjes gaan maken in de toekomst. **Mieke**, enorm bedankt voor alle gezelligheid, hulp en af en toe een luisterend oor. Het was top om samen met jou de celkweek

filmpjes op te nemen. Wij hebben nu eeuwige roem en daar mogen we heel trots op zijn! **Jenny**, het kweken van organoids, cellen, co-culturen, niks was ons te gek! Ik vond het heel leuk met je samen te werken, bedankt voor de gezellige momenten! **Shohreh**, you already supervised me during my MSc thesis, longggg time ago. I really appreciate that you were always willing to help, and of course thanks for all the cookies and candy :-)

**Marlies**, als overbuurvrouw wil ik jou ook bedanken voor alle gezelligheid en je interesse. Wij namen altijd stevast het weekend door op de maandagochtend, dat ga ik zeker missen! **Guido**, bij jou kon ik altijd terecht voor prangende vragen over alles wat met data analyse te maken had. Ook wist ik je te vinden als ik weer eens een GEO nummer nodig had. Daarnaast heb ik je nuttige en leerzame feedback op mijn resultaten tijdens de labmeetings en Gut Health meetings altijd zeer gewaardeerd, dank daarvoor! **Carolien**, jij hebt me van begin af aan geholpen in het lab en ik kon me geen betere begeleider wensen! Ik ben je ontzettend dankbaar voor alles wat ik van je heb geleerd. Daarnaast was het ook nog eens heel gezellig om je collega te zijn!

**Dieuwertje**, wij hebben elkaar ook al tijdens mijn Master thesis leren kennen. Ik heb veel van je geleerd in de periode dat wij parallel aan de IDEAL samples werkten. Dank voor de momenten waarop we samen over de resultaten konden sparren! **Jocelijn**, bedankt voor je hulp en feedback op mijn *in vitro* darmmodellen. Ook je grondige feedback op de bile acid paper was zeer nuttig!

**Rinke**, ik gok dat 9 van de 10 gesprekken die wij voerden over de fiets gingen :-)

Dankjewel voor de gezelligheid en uiteraard ook voor je hulp/ideeën over de experimenten met de DCs. **Lydia**, ook onze gesprekken gingen vaak over uiteenlopende onderwerpen. Maar er was altijd genoeg om het met je over te hebben en het was in ieder geval altijd erg gezellig, dank hiervoor!

**Pieter, Mark, Klaske, Michiel, Marco, Nhien**, bedankt voor jullie interesse in mijn onderzoek! **Nikkie**, ik vind het leuk dat je weer (deels) terug bij Humane Voeding bent teruggekomen. Dank voor je interesse en dat je me op gang hebt geholpen met de organoids!

**Anna**, so nice that you joined our group! I really like working together with you and talk about our experiments. Thanks a lot for your help in the lab and your interest in my research!

**Rieneke**, onze gesprekken bij de koffiemachine gingen uiteraard altijd over onze gezamenlijke passie: sport! Ik vond het heel leuk om jouw inzichten en ervaringen hierover te horen. Wie weet komen we elkaar nog een keer tegen bij een RBR of triatlon!

**Pol**, wij hebben de afgelopen jaren ook heel wat onvergetelijke momenten op de fiets meegemaakt, zoals onze 200 km-rit, samen tegeltjes zoeken, op KOM/QOMetjes jacht, MTB met hongerklop (incl. saucijzenbroodje-to-the-rescue) en zo kan ik nog wel even doorgaan :-)

Maar altijd met serieuze en soms minder serieuze gesprekken. Heel erg bedankt voor alle gezelligheid, en natuurlijk ook dat ik af en toe even in je wiel mocht kruipen!

**Aafke**, het was super fijn om als groentje naast zo'n ervaren aio te mogen zitten op kantoor. Dank voor al je wijze raad! Daarnaast konden we goed

met elkaar over ons onderzoek sparren, daar heb ik veel van geleerd! **Maarten**, wat was het altijd relaxed om met jou het practicum in goede banen te leiden. Jij had altijd wel een goede oplossing als het in de soep dreigde te lopen. Ook op de fiets hebben we heel wat gezellige momenten beleefd, dankjewel daarvoor! **Maartje**, wat ben ik blij dat je ik je heb mogen begeleiden tijdens je stage! Jouw gedrevenheid, motivatie, labskills, harde werk en natuurlijk je gezelligheid heb ik altijd enorm gewaardeerd. Dank voor al je hulp tijdens mijn onderzoeken!

**Clara**, de afgelopen jaren hebben wij heel wat keren samengewerkt. Heel erg bedankt voor je hulp op microbiologisch gebied en natuurlijk voor de kans die je me gegeven hebt om aan de *Akkermansia* studie te werken!

**Noortje**, dankjewel dat ik altijd bij je terecht kon voor mijn vragen over galzouten en *in vitro* modellen! Ik vond het altijd heel leuk om bij je langs te komen in Utrecht en te sparren over m'n onderzoek. Heel erg bedankt voor je behulpzaamheid en je goede inzichten. Wie weet mogen we in de toekomst nog eens samenwerken!

**Lianne**, wij hebben van begin af aan onze studie samen doorlopen! Ik heb zo'n goede herinneringen aan deze tijd, van samen uitbrakken in de collegezaal, ochtendzwemsessies met een Hema-ontbijtje, samen hardlopen in het Arboretum en natuurlijk alle hardloopwedstrijden. Ik vind het super dat jij ook aan een PhD bent begonnen! Ook al wonen we niet meer zo dicht bij elkaar, laten we nog heel vaak afspreken en samen gouden medailles gaan winnen!

**Lily**, als ervaringsdeskundige kon ik altijd bij je terecht voor raad en daad op het gebied van promoveren. Eerst als collega's, daarna tijdens urenlange telefoongesprekken of wandelingen met slechte cappuccino. Dankjewel voor al deze momenten en natuurlijk ook voor je cursus 'Omgaan met een PhD voor dummies' ;-). Onze epische fietsritjes (inclusief kuitkrampen, gigantische verdwalingen en irritante vouwfietzers) zullen me altijd bijblijven, ik hoop dat er nog heel veel gaan komen (maar we zijn weer op de goede weg)!

Alle supermenckies: **Frans, Gerrie, Hidde** en **Suzanne**, heel erg bedankt voor jullie gezelligheid de afgelopen jaren. Ik vond het super dat jullie altijd zo geïnteresseerd in mijn onderzoek waren. Dank voor alle fijne momenten samen! **Jasmijn**, ik vond het zo leuk dat jij er voor koos om naar Wageningen te komen om ook Voeding & Gezondheid te gaan studeren! Het was altijd gezellig om met je te kletsen over je studie en mijn PhD. Ook de etentjes samen met Bob en Thijs erbij waren erg geslaagd!

**Roel, Josta, Ilona** en **Ruben**, ik kan me geen betere broer, zus, schoonzus en zwager wensen. De bezoeken aan jullie behoren tot mijn meest favoriete bezigheden! Maar ik zal niet onder stoelen of banken steken dat **Fedde, Thijmen** en **Boris** hier een grote rol in spelen ;-). En uiteraard speciale dank voor Ruben voor de omslag van dit boekje! **Papa** en **mama**, dank voor jullie onvoorwaardelijke steun en vertrouwen in mij. Ik vond het altijd fijn om het met jullie te hebben over het wel en wee van mijn PhD. En natuurlijk dank voor de regelmatige etentjes met de hele bups, die boden altijd een welkome afleiding!

Tenslotte gaat mijn dank uit naar de allerliefste **Bob**. De afgelopen jaren hebben maar weer eens bewezen dat team B&B alles aankan. Je altijd bemoedigende woorden als het wat minder ging (*'kom op slappe'*), je 'pragmatische' instelling en natuurlijk je bijzonder gedetailleerde Excel-planningen hebben mij in het gareel gehouden, waardoor ik de eindstreep heb kunnen halen. Het leven samen met jou is een groot feest. Laten we samen nog veel avonturen gaan beleven!

## About the author

## CURRICULUM VITAE

Benthe Mathilde van der Lugt was born on June 8, 1993 in Wanroij, the Netherlands. After completing secondary school at the Merletcollege in Cuijk in 2011, she started the bachelor Nutrition and Health at Wageningen University. After successful completion in 2014, she continued with the master program Nutrition and Health with the specialization Molecular Nutrition & Toxicology. During her master program, she enrolled in the Research Master Cluster, which is a program initiated by VLAG that prepares MSc students in the process of becoming a PhD student. During the Research Master Cluster, she participated in several courses and activities and wrote a full PhD proposal. In parallel, she completed a MSc thesis at the Nutrition, Metabolism and Genomics group at Wageningen University under supervision of dr. Wilma Steegenga. She investigated the effects of a life-long intermittent diet, alternating between caloric restriction and a medium fat diet, on colonic health. For her internship, she moved out of Wageningen and ended up in the south of Germany. At the Technische Universität München, she investigated the role of the MFS transporter in IL-10<sup>-/-</sup> mouse monoassociated with *E. faecalis*, under supervision of prof. dr. Dirk Haller. In the meantime, she received the great news that her PhD proposal was selected for funding. In September 2016, after receiving her master's degree, she started her PhD project under the supervision of dr. Wilma Steegenga and prof. dr. Sander Kersten. The results of this PhD project are described in this thesis, entitled: *'Breaking down the barriers: The effects of aging, gut microbiota and bile acids on intestinal health'*.
