

The role of *CBL* genes in the salt stress response of *Nicotiana tabacum*

Jingjing Mao

Propositions

1. H^+ homeostasis is as important as Na^+ homeostasis for the salt tolerance of plants.

(this thesis)

2. Our current knowledge about ion distribution over different cell organelles is inadequate in understanding plant response to salinity stress.

(this thesis)

3. Statistical significance is often misused to describe physiological significance.

4. ChatGPT is harmful to researchers who lack independent thinking.

5. Caring too much about other people's opinions makes people lose themselves.

6. Moderate stress makes both plants and humans stronger.

Chapter 1

1

General Introduction

Climate change leads to increasing stresses and reduction of crop yield

Anthropogenically driven climate change is increasing the frequency of weather extremes (Cook et al., 2016), which directly and indirectly affects agricultural production. The changes in exposure of crops to abiotic environmental factors not only directly affect crop production, but climate change also affects other species such as pollinators, pests, disease vectors, and invasive species, indirectly impeding crop production (Liliane and Charles, 2020). Moreover, crops are usually not subject to a single stress, but to a combination of different stresses in the field (Mittler, 2006). These stresses lead to yield losses that threaten the increasing food needs of a growing world population (Ferguson, 2019). It is therefore of the utmost importance for plants and crops to be able to adapt to these changing conditions, and have high yields even when the growing conditions are not optimal. Knowledge about the adaptive strategies and mechanisms to changing environmental conditions is essential for breeders to develop varieties that are resilient to the changing climate.

Stress and the second messenger Ca^{2+}

Plants perceive stresses and respond appropriately through signaling pathways, which include signaling molecules such as Ca^{2+} (Bartels and Sunkar, 2005). Many years ago, researchers already showed that different environmental stimuli induced specific cytosolic Ca^{2+} concentration spikes ($[\text{Ca}^{2+}]_{\text{cyt}}$ transients) (Price et al., 1994; Haley et al., 1995; Bush, 1996; Okazaki et al., 1996; Gong et al., 1998; McAinsh and Hetherington, 1998). When triggered, the $[\text{Ca}^{2+}]_{\text{cyt}}$ increases from $\sim 10^{-7}$ M to 10^{-6} M depending on the kind of external stimulus (Costa et al., 2018), generating unique $[\text{Ca}^{2+}]_{\text{cyt}}$ signatures that initiate specific molecular and physiological responses to diverse developmental cues and environmental stimuli (Lee and Seo, 2021).

Increased $[\text{Ca}^{2+}]_{\text{cyt}}$ is caused by the release of Ca^{2+} from storage compartments such as the vacuole and the apoplast (Stael et al., 2012). The central vacuole is the main intracellular Ca^{2+} store and contributes to changes in $[\text{Ca}^{2+}]_{\text{cyt}}$ (Stael et al., 2012). Vacuolar Ca^{2+} release in the cytosol leads to the propagation of systemic Ca^{2+} waves

throughout the whole plant (Choi et al., 2014; Evans et al., 2016; Lee and Seo, 2021). The apoplast is another important Ca^{2+} storage location and Ca^{2+} can be quickly transported through the plant by means of the water transpiration stream (Stael et al., 2012). The endoplasmic reticulum (ER) is well known for its important calcium storage role in humans and animals, while relatively little is known about the Ca^{2+} storage properties of the plant ER. The plant ER was reported to act as a Ca^{2+} source for the generation of a cytosolic Ca^{2+} transient (Shkolnik et al., 2018; Luo et al., 2020) as well as a Ca^{2+} sink that contributes to the dampening of Ca^{2+} transient (Bonza et al., 2013; Corso et al., 2018; Resentini et al., 2021).

The $[\text{Ca}^{2+}]_{\text{cyt}}$ increase requires specific signals and Ca^{2+} transport routes from the apoplastic fluid or intracellular compartments into the cytosol (Navazio et al., 2000; Vincent et al., 2017). With advanced bioimaging techniques, stress-sensing machinery components have been identified, such as lipid-binding proteins, membrane-anchored kinases, and Ca^{2+} channels (Lee and Seo, 2021). These molecular sensors recognize external cues such as osmotic stress, ionic stress, pathogens, extracellular ATP, and reactive oxygen species (ROS), initiating a corresponding Ca^{2+} influx in the cytosol (Lee and Seo, 2021).

CBL-CIPK network decodes Ca^{2+} signals

The transduction of Ca^{2+} signals triggered by environmental stimuli to downstream adaptive responses depends on Ca^{2+} -sensor proteins (Trewavas and Malhó, 1998). To date, five major classes of Ca^{2+} sensor proteins have been characterized in plants: calmodulins (CaMs), CaM-like proteins (CMLs), calcium-dependent protein kinases (CDPKs), calcium- and calmodulin-dependent protein kinases (CCaMKs), and calcineurin B-like proteins (CBLs) (Yip Delormel and Boudsocq, 2019). All of these Ca^{2+} -sensor families are known to transmit stress signals (Zhu, 2000; Snedden and Fromm, 2001; Luan et al., 2002; Singh and Parniske, 2012). In *Arabidopsis thaliana*, 7 CaMs (McCormack et al., 2005), 50 CMLs (McCormack et al., 2005), 34 CDPKs (Hrabak et al., 2003), and 10 CBLs (Kolukisaoglu et al., 2004) have been identified.

CCaMKs are absent in *Arabidopsis* and are required for both root nodule and arbuscular mycorrhiza symbioses in legumes (Singh and Parniske, 2012). CBLs act together with CIPKs (CBL-interacting protein kinases) by activating CIPK phosphorylation, and each CBL-CIPK module triggers specific downstream responses. CBLs and CIPKs thus are interwoven in a complex but flexible Ca^{2+} -signal-decoding hub in plants (Figure 1). Therefore, the CBL family plays an essential role in regulating physiological development and the response to external stress stimuli in plants (Luan, 2009; Weinl and Kudla, 2009).

Figure 1 The CBL-CIPK regulatory network in *Arabidopsis thaliana*. The figure is modified based on (Ma et al., 2020; Mao et al., 2022). AtCBLs can be divided into three types (type I, II, and III) (Kleist et al., 2014). Pointed and blunt arrowheads indicate activating and inhibitory connections, respectively. The dotted lines indicate proposed connections that still require validation.

For Ca^{2+} -binding, CBL proteins feature four EF-hands that are formed by conserved α -helix-loop- α -helix structures (Sánchez-Barrena et al., 2013). The Ca^{2+} binding affinity of EF-hands can vary within and between CBLs, which is assumed to enable specific and appropriate responses to the specific $[\text{Ca}^{2+}]_{\text{cyt}}$ signatures of different stimuli. When bound with Ca^{2+} , the molecular surface properties of CBL change. This

change contributes to the interaction of the CBL protein with the NAF domain (named after the highly conserved amino acids Asn (N), Ala (A), Phe (F)) of the CIPK, (Sánchez-Barrena et al., 2013). Once combined with its CBL counterpart, the phosphorylation site located in the CIPK activation loop is uncovered, turning its auto-inhibited state into an active state and thereby authorizing it to phosphorylate downstream substrates (Guo et al., 2001; Nunez-Ramirez et al., 2012; Sánchez-Barrena et al., 2013). This phosphorylation is reversible, which is important for organisms to modulate cellular processes in response to environmental cues. One of the better established roles of CBL-CIPK in stress tolerance is its regulation of ion homeostasis under salt stress (Figure 2).

Plant adaptation to salt stress

Salinity stress is characterized by a high concentration of soluble salts (often NaCl) in the soil with a soil electrical conductivity (EC) measured in the saturated extract (ECe) of 4 dS/m or more at 25°C, which is equivalent to approximately 40 mM NaCl (Richards, 1954). Glycophytes including the most important food crops often have growth and yield penalties already at 5 dS/m, while halophytes can withstand much higher salinity levels and may have optimal growth at soil salinity ranging from 20-40 dS/m (Flowers and Colmer, 2015; Joshi et al., 2015).

Salt stress imposes both osmotic stress and ionic stress on plants (Munns, 2005). The osmotic effect triggered by salt stress is similar to that triggered by drought stress. The osmotic effect makes it harder for roots to take up water because of the difference in osmotic potential between the saline soil and roots. At the cellular level, both stresses cause cellular dehydration, leading to a decrease in the cytosolic and vacuolar volumes (Bartels and Sunkar, 2005; Munns and Tester, 2008). The stress from water deficiency also affects the electron-transport chains of mitochondria and chloroplasts, which results in excessive ROS production and oxidative stress. This secondary oxidative stress modifies cellular structures and metabolism, leading to a decrease in photosynthesis and/or an increase in plant hormones such as ABA and

ultimately cell and tissue damage (Bartels and Sunkar, 2005).

In addition to osmotic stress, salinity leads to ion accumulation in plants (Munns, 2005; Munns and Tester, 2008). Na^+ appears to reach a toxic concentration before Cl^- does for most species (Munns and Tester, 2008), so most studies focus on Na^+ accumulation in different plant tissues when it comes to salt stress. Under continuous salt stress, Na^+ is transported to the leaf blades with the transpiration stream and is deposited there, because only a small proportion of the Na^+ can be recirculated to roots through phloem for most plants (Tester, 2003). Na^+ and Cl^- accumulate over time, and become toxic when they reach a threshold (Munns and Tester, 2008). The threshold of cytosolic Na^+ and Cl^- concentration varies between plant species. Some reports claim that the threshold of cytosolic Na^+ concentration is ~ 30 mmol/L while others suggest a range between 50 and 200 mmol/L (Wu, 2018). The toxic threshold of the cytosolic Cl^- concentration is reported to be 4-7 mg/g DW (~ 11 -19 mmol/L) for Cl^- sensitive species and 15-50 mg/g DW (~ 42 -141 mmol/L) for Cl^- -tolerant species (Tavakkoli et al., 2010).

Adaptation to salinity requires many complex physiological changes, including reduced photosynthesis and transpiration, attenuated growth, accumulation of compatible solutes and protective proteins, and increased levels of antioxidants (Bartels and Sunkar, 2005). Plants have developed many strategies to minimize damage from salt stress, such as enhancing tolerance to osmotic stress, promoting Na^+ exclusion from leaf blades, and enhancing tissue tolerance to Na^+ accumulation (Munns and Tester, 2008). Minimizing the net delivery of Na^+ into the root xylem and minimizing the concentration of salt in the cytoplasm are particularly important for plants to survive (Munns, 2005). The inhibition of Na^+ accumulation in the cytoplasm entails salt excretion and salt compartmentalization.

Using Ca^{2+} -imaging techniques, plants were shown to be able to distinguish osmotic and ionic stress by different sensing modules and induce corresponding specific Ca^{2+} signals (Lee and Seo, 2021). Ionic stress and osmotic stress stimulate different

primary Ca^{2+} signals through different pathways of the stress-sensing machinery. The osmotic stress-sensing machinery includes the hyperosmolality-gated Ca^{2+} -permeable channel OSCA1 localized at the plasma membrane (Yuan et al., 2014). OSCA1 is anchored to the lipid bilayer and can perceive membrane tension changes induced by turgor pressure (Jojoa-Cruz et al., 2018; Liu et al., 2018; Maity et al., 2019). The sphingolipid GIPCs (glycosylinositol phosphorylceramide) are the major constituents of the outer layer of the lipid bilayer in the plasma membranes of plants and are important components of the ionic stress-sensing machinery under salt stress. GIPCs can directly bind with Na^+ and other ions that have a single positive charge, such as K^+ and Li^+ (Cacas et al., 2016; Jiang et al., 2019; Mamode Cassim et al., 2021). Direct binding of Na^+ by GIPCs and directly/indirectly interacting between GIPC and Ca^{2+} channels are essential in plant Na^+ sensing and the increase of $[\text{Ca}^{2+}]_{\text{cyt}}$ that lead to salt-tolerance responses (Jiang et al., 2019; Steinhorst and Kudla, 2019).

CBL-CIPK pathways and salt stress response

For different Ca^{2+} signals triggered by different degrees of stress, plants employ different Ca^{2+} sensors (Mehra and Bennett, 2022; Steinhorst et al., 2022). Steinhorst et al. (2022) found that the amplitude of the Ca^{2+} signal as well as the speed of the resulting Ca^{2+} wave is proportional to the intensity of salt stress, and different intensities of Ca^{2+} waves may be decoded by different CBL members (Mehra and Bennett, 2022; Steinhorst et al., 2022).

AtCBL4 is well known to work with AtCIPK24 to phosphorylate and activate the Na^+/H^+ antiporter SOS1 (the SOS (Salt Overly Sensitive) pathway), resulting in Na^+ extrusion from the roots into the root environment and Na^+ loading into the xylem for long-distance transport driven by the transpiration stream from root to shoot (Figure 2) (Shi et al., 2002). The SOS pathway has also been identified in many other plant species (Martinez-Atienza et al., 2007; Tang et al., 2010; Hu et al., 2012). Recently, AtCBL8 was suggested to be a Ca^{2+} -sensor switch for enhanced efficiency of the

SOS pathway based on the following experimental evidence (Mehra and Bennett, 2022; Steinhorst et al., 2022): *At-cbl8* mutants only exhibit salt sensitivity under high degrees of salt stress (75 mM or 100 mM NaCl), while *At-cbl4* mutants are sensitive to a very low degree of salt stress (25 mM NaCl). In addition, AtCBL8-AtCIPK24 was evidenced to activate SOS1 in yeast and human HEK293T cells (Mehra and Bennett, 2022; Steinhorst et al., 2022). Furthermore, different from AtCBL4, the structural conformation, interaction with AtCIPK24, and AtCIPK24-mediated phosphorylation of AtCBL8 are all Ca^{2+} dependent. These factors together all indicate that the AtCBL8-AtCIPK24 pathway activates SOS1 when a higher $[\text{Ca}^{2+}]_{\text{cyt}}$ level is reached under high salt stress (Figure 2).

AtCBL10 also functions in the SOS pathway. AtCBL10-AtCIPK8/24 complexes phosphorylate SOS1 and enhance Na^+ efflux from cells (Figure 2) (Quan et al., 2007; Lin et al., 2009; Yin et al., 2019). Moreover, the AtCBL10-AtCIPK24 complex was suggested to activate a Na^+/H^+ antiporter to sequester Na^+ into the vacuole for salt storage and detoxification of the cytosol (Kim et al., 2007), but the antiporter is not identified yet. Other research suggested that AtCBL10-AtCIPK24 may drive Na^+ compartmentalization by activating the vacuolar H^+ pump H^+ -pyrophosphatase (AVP1) and vacuolar H^+ -ATPase (VHA-A1) to generate an electrochemical gradient of H^+ (Figure 2) (Plasencia et al., 2021).

Figure 2 Schematic picture to show the important CBL-CIPK pathways in salt stress response.

Pointed arrowheads indicate activating processes. The dotted lines indicate proposed connections that still require validation. The question mark (?) means the Na^+/H^+ antiporter has not been identified yet. The red lightning sign with a "P" inside means phosphorylation.

The salt tolerance and tobacco *CBL* genes

The role of the CBL-CIPK pathway is studied well in *Arabidopsis* but much less in other crops including representatives of the *Solanaceae*. Cultivated tobacco (*Nicotiana tabacum*) is a member of the *Solanaceae* family including important crops like tomato, potato, and pepper. Identification and characterization of salt stress-related tobacco genes can unlock their potential to improve the salt stress tolerance of tobacco, and the results are potentially translatable to other *Solanaceae* crops thus benefiting the sustainable production of these important vegetable crops. *N. tabacum* is a natural allotetraploid derived from the maternal genome donor *N. sylvestris* and the paternal genome donor *N. tomentosiformis* (Murad et al., 2002; Yukawa et al., 2006). Tobacco can generate up to 170 tons/ha of green tissue and 600 kg/acre of seeds that can be used for producing biomass, biofuel, seed oil, and antibodies (Schillberg et al., 2003; Andrianov et al., 2010; Grisan et al., 2016). In

addition, tobacco is widely considered to be a model plant for fundamental research, because of its available high-quality genome sequence, easily-operated genetic transformation, and short reproduction cycle. This makes tobacco an interesting model plant to study the role of *CBL* genes as decoding hubs of salt stress stimuli.

Objectives and scope of this thesis

The research described in this thesis was initiated to enhance our understanding of the roles of tobacco *NtCBL* genes in the response to salt stress, and their possible contribution to salt tolerance. The present thesis consists of six chapters including this general introduction (**Chapter 1**).

In **Chapter 2**, we reviewed the role of the CBL-CIPK network in the physiological crosstalk between plant growth and stress adaption.

In **Chapter 3**, a genome-wide analysis of the *NtCBL* gene family in tobacco was performed to identify *CBL* family members in tobacco. Their genic and protein structural features were discussed, and expression profiles in different tissues at different developmental stages and under salt stress were analyzed. The *NtCBL4A-1* gene from the ancestral *N. sylvestris* genome was characterized in more detail because of its potential role in the salt stress response.

In **Chapter 4**, we focused on another member of the CBL family that was suggested to play a role in salt tolerance: CBL5. Tobacco plants overexpressing *NtCBL5A* were evaluated under saline conditions and were shown to be hypersensitive to salinity (expressed as highly necrotic leaves). This hypersensitive phenotype was shown to be potentially linked to abnormal Na⁺ compartmentalization, plant photosynthesis, and plant immune response triggered by the constitutive overexpression of *NtCBL5A*.

The results described in Chapter 3 and Chapter 4 suggest that the (ectopic) overexpression of *NtCBL4A-1* and *NtCBL5A* may interfere with the function of other CBL-CIPK modules. In **Chapter 5**, we assessed the salt tolerance of *NtCBL4A-1::NtCBL5A* co-overexpressing lines and *NtCBL10A::NtCBL5A* co-overexpressing lines. Results showed that co-overexpression of *NtCBL4A-1* and *NtCBL5A* has an

additive effect on the salt sensitivity of transgenic tobacco, while *NtCBL10A* overexpression greatly relieved the salt sensitivity of *NtCBL5A*-OE lines. This indicates that the salt sensitivity caused by *NtCBL4A-1* overexpression and *NtCBL5A* overexpression may be linked to the function of *NtCBL10A*. This was corroborated by the fact that *NtCBL4A-1*, *NtCBL5A*, and *NtCBL10A* interact with the same *NtCIPK24* in the yeast two-hybrid system. Increased salt sensitivity of *Nt-cbl10a* single mutants and *Nt-cbl10b* single mutants, and the hypersensitivity of the *Nt-cbl10acb10b* double mutants further demonstrate that *NtCBL10A* and *NtCBL10B* are key components for salt tolerance of tobacco.

In **Chapter 6**, I summarized all findings and discussed our hypothesis on the salt-sensitive phenotypes induced by the overexpression of *NtCBL4A-1*, *NtCBL5A*, and the knock-out of *NtCBL10*. In addition, I discussed some findings in our research, which are useful to understand the salt stress response of plants.

Published in Plant, Cell, & Environment (2022)

ABSTRACT

Plants have evolved to deal with different stresses during plant growth, relying on complex interactions or crosstalk between multiple signaling pathways in plant cells. In this sophisticated regulatory network, Ca^{2+} transients in the cytosol ($[\text{Ca}^{2+}]_{\text{cyt}}$) act as major physiological signals to initiate appropriate responses. The CALCINEURIN B-LIKE PROTEIN (CBL)-CBL-INTERACTING PROTEIN KINASE (CIPK) network relays physiological signals characterized by $[\text{Ca}^{2+}]_{\text{cyt}}$ transients during plant development and in response to environmental changes. Many studies are aimed at elucidating the role of the CBL-CIPK network in plant growth and stress responses. This review discusses the involvement of the CBL-CIPK pathways in two levels of crosstalk between plant development and stress adaptation: direct crosstalk through interaction with regulatory proteins, and indirect crosstalk through adaptation of correlated physiological processes that affect both plant development and stress responses. This review thus provides novel insights into the physiological roles of the CBL-CIPK network in plant growth and stress adaptation.

Keywords: CBL, CIPK, crosstalk, plant development, abiotic stress, biotic stress, stress adaptation

1 INTRODUCTION

During their lifecycle, plants are continuously exposed to a plethora of abiotic and biotic stresses. Being sessile, plants need to develop defense mechanisms to adapt to these stresses and not only survive but also grow and reproduce (Shanker and Venkateswarlu, 2011). Stress responses typically come at the cost of growth and yield in crops (Huot et al., 2014; Karasov et al., 2017). More and more studies show that the negative correlations between growth and defense are partially caused by crosstalk between sophisticated molecular regulatory pathways (Karasov et al., 2017). These regulatory networks connect plant growth and stress tolerance, enabling a rapid adaptation of plant metabolism to mitigate the effects of the constantly changing environmental conditions. Campos et al. (2016) have shown

that it is in principle possible to uncouple pathways involved in the crosstalk between plant growth and defense, thus considerably reducing the trade-off of growth for defense. Knowledge of the integration of the molecular regulatory networks related to stress response and plant development may therefore be crucial for yield improvement of crops in a changing environment.

Ca^{2+} is a vital secondary messenger for both plant development and early stress responses (Hepler, 2005; Kudla et al., 2010; Reddy et al., 2011; Steinhorst and Kudla, 2014). Specific $[\text{Ca}^{2+}]_{\text{cyt}}$ transients are triggered in the cytoplasm when plants are exposed to environmental stimuli (Price et al., 1994; Haley et al., 1995; Okazaki et al., 1996; Gong et al., 1998). The $[\text{Ca}^{2+}]_{\text{cyt}}$ transients are recognized by calcium sensors that relay the Ca^{2+} signals to downstream response pathways. These sensors include CALCINEURIN B-LIKE PROTEINs (CBLs) that bind Ca^{2+} through EF-hand motifs (Sánchez-Barrena et al., 2013). The naming "EF-hand" describes its helix-loop-helix structure that resembles a right hand with the thumb (F-helix) and the forefinger (E-helix) extended at 90° (Kretsinger and Nockolds, 1973). Upon binding Ca^{2+} , the molecular surface properties of the CBL proteins are modified (Sánchez-Barrena et al., 2013). This facilitates the interaction of CBL with the NAF domain of a CBL-INTERACTING PROTEIN KINASE (CIPK) (Sánchez-Barrena et al., 2013). The Ca^{2+} -induced interaction of CBL with CIPK uncovers a phosphorylation site located in the activation loop of the CIPK protein (Sánchez-Barrena et al., 2013). The exposed activation loop of the CIPK protein is assumed to be phosphorylated and activated by as yet unknown upstream kinases (Sanyal et al., 2015). The activated CIPK protein typically phosphorylates and thus regulates multiple downstream targets (Sánchez-Barrena et al., 2013), including ion channels and enzymes (Nunez-Ramirez et al., 2012; Drerup et al., 2013). An exception for this general activation mechanism of CBL-CIPK was reported for potassium channel AKT2, which was shown to be activated by the interaction with but not the phosphorylation by the CBL-CIPK complex (Held et al., 2011).

The CBL-CIPK modules, as part of environmental signaling pathways, are well-

conserved across the plant kingdom. With the availability of the whole-genome sequence data of many plant species, the evolution of the CBL-CIPK network (from green algae to flowering plants) can be studied (Weinl and Kudla, 2009; Kleist et al., 2014; Edel and Kudla, 2015). A single CBL-CIPK pair is present in green algae *Chlorella spec.*, suggesting that the prototype of this signaling module may date back to single-cell plant ancestors (Weinl et al., 2009; Edel and Kudla, 2015; Tang et al., 2020a). The number of CBL and CIPK members expanded from lower plants to higher plants by gene duplication and whole-genome duplication events, indicating that the CBL-CIPK network plays an essential role in plant adaptation to a changing environment (Kleist et al., 2014).

Numerous expression and functional studies have demonstrated the broad involvement of the CBL-CIPK network in plant development and stress response. Recently, more and more studies indicate that the CBL-CIPK network connects plant development and stress adaptation at two levels. At the first level, the CBL-CIPK complexes directly interact with regulatory components involved in plant development and stress response. At the second level, the physiological adaptations regulated by CBL-CIPK pathways in response to stress affect plant growth and development, and vice versa.

2 LEVEL 1: The CBL-CIPK MODULES CONNECT PLANT DEVELOPMENT AND STRESS ADAPTATION BY INTERACTING WITH REGULATORY PROTEINS

The SALT OVERLY SENSITIVE (SOS) pathway is the first CBL-CIPK pathway that was uncovered in *Arabidopsis thaliana* and it is a well-studied example of crosstalk through direct interaction of components involved in plant development and stress adaptation. Under saline conditions, the induced Ca^{2+} transient promotes the phosphorylation activity of the AtCBL4-AtCIPK24 complex which activates the plasma membrane (PM)-localized Na^+/H^+ antiporter AtSOS1, leading to Na^+ extrusion from the roots into the root environment and Na^+ loading into the xylem for long-distance transport (Qiu et al., 2002; Shi et al., 2002; Nunez-Ramirez et al.,

2012). The SOS pathway is conserved in other plant species such as rice, poplar, and apple (Mao et al., 2021). Of all AtCIPKs, AtCIPK8 resembles AtCIPK24 the most (60.9% AA pairwise identity) (Kleist et al., 2014), and it has been shown that the AtCBL10-AtCIPK8 complex also functions in the SOS pathway, positively regulating AtSOS1 activity to extrude excess Na^+ from cells in the shoot under saline conditions (Yin et al., 2019).

Under normal conditions, the SOS pathway is suppressed by several proteins including 14-3-3, BRASSINOSTEROID INSENSITIVE 2 (BIN2), and GIGANTEA (GI). These proteins interact with AtCIPK24 and repress its kinase activity (Kim et al., 2013; Zhou et al., 2014; Yang et al., 2019; Li et al., 2020), thus working as molecular switches of the SOS pathway during dynamic growth and floral transition under varying soil salinity (Figure 1) (Kim et al., 2013; Park et al., 2013).

Plant 14-3-3 proteins, like their highly conserved homologs in mammals, function by binding to phosphorylated target proteins and thus modulating their function (Denison et al., 2011). Under normal conditions, AtCIPK11 phosphorylates Ser²⁹⁴ of AtCIPK24 and this promotes the interaction of AtCIPK24 with 14-3-3 proteins, which blocks AtCIPK24 activity and shuts down the SOS pathway. Under saline conditions, the interaction between 14-3-3 and AtCIPK11 is stimulated, releasing AtCIPK24 (Yang et al., 2019). The released AtCIPK24 then interacts with Ca^{2+} -binding AtCBL4, thus activating downstream AtSOS1 to regulate cellular Na^+ homeostasis (Qiu et al., 2002; Shi et al., 2002; Nunez-Ramirez et al., 2012).

The SOS pathway is also linked to plant growth through BIN2, a GLYCOGEN SYNTHASE KINASE 3 (GSK3)-like kinase. BIN2 phosphorylates and represses the transcription factors BRASSINAZOLE RESISTANT 1 (BZR1) and BRI1-EMS-SUPPRESSOR (BES1) and thus retards plant growth under salt stress (Li et al., 2020). In the rapid recovery phase after salt stress, however, AtCBL4 and AtCBL10 interact with BIN2 and recruit it to the PM. BIN2 then phosphorylates AtCIPK24 and inhibits the kinase activity of AtCIPK24, effectively switching off the AtSOS1-induced

Na⁺ efflux. At the same time, the repression of the transcriptional activity of BZR1/BES1 by BIN2 is released, and growth is restored (Li et al., 2020).

Figure 1 | SOS pathway is involved in the crosstalk between plant growth and salt stress response.

(A) The interaction between GI and SOS pathway (Kim et al., 2013; Park et al., 2013). Under normal conditions (left side of the figure), GI interacts with AtCIPK24 and inhibits its activity, therefore AtCIPK24 does not interact with AtCBL4 and cannot phosphorylate AtSOS1. Salt stress (right side of the figure) induces the degradation of GI, releasing AtCIPK24. AtCIPK24 then interacts with PM-localized Ca²⁺-binding AtCBL4 and activates AtSOS1. At the same time, salt-dependent degradation of GI retards or abolishes the initiation of flowering. **(B)** A proposed working model of the role of the SOS pathway in the dynamic growth of plants when switching between normal and salinity conditions (Li et al., 2020). Under normal conditions, AtCIPK11 phosphorylates AtCIPK24 and promotes its interaction with 14-3-3, inhibiting AtCIPK24 activity. BZR1/BES1 stimulates plant growth. Under salt stress, AtCBL4/AtCBL10 recruits

AtCIPK24 to the PM to activate AtSOS1. BIN2 is disassociated from the PM to phosphorylate and inhibit BZR1/BES1, thus retarding plant growth. In the recovery phase, AtCBL4/AtCBL10 recruits BIN2 to the PM to inhibit the activity of phosphorylated AtCIPK24. This reduces Na⁺ efflux and releases BZR1/BES1 to stimulate plant growth. Black pointed and blunt arrowheads indicate activating and inhibiting interactions, respectively.

AtCIPK24 also interacts with GI, a nuclear protein that functions to promote the elicitation of photoperiod-dependent flowering (Park et al., 1999; Oliverio et al., 2007; Kim et al., 2013). Under normal conditions, GI interacts with AtCIPK24 and prevents AtCIPK24 from phosphorylating AtSOS1. Under saline conditions, however, the AtCIPK24-GI complex disintegrates and GI is then degraded, leading to delayed flowering (Figure 1). At the same time, the SOS pathway is activated to regulate Na⁺ homeostasis and Na⁺ extrusion (Kim et al., 2013; Park et al., 2013). This is consistent with the finding that *GI*-overexpressing *Arabidopsis* plants exhibited a salt-sensitive phenotype and *gi* mutants had increased salt tolerance (Kim et al., 2013).

One CIPK can be regulated by different proteins (AtCIPK24 by AtCIPK11, GI, 14-3-3, and BIN2). These interactions of CIPKs with other proteins provide the molecular basis for the first level of direct crosstalk between plant growth and stress response.

3 LEVEL 2: THE CBL-CIPK MODULES CONNECT PLANT DEVELOPMENT AND STRESS ADAPTATION BY MODULATING CORRELATED PHYSIOLOGICAL PROCESSES

To adapt to stress conditions, new biochemical pathways are activated and others that are characteristic of the non-stressed state are repressed in plants (Bohnert and Sheveleva, 1998). Protective metabolic adaptation of plants includes changes in phytohormones, ion homeostasis, and the concentration of metabolites such as sugars, sugar alcohols, low-complexity carbohydrates, tertiary amines, sulfonium compounds, and amino acids (Bohnert et al., 1998; Wolters and Jurgens, 2009). These metabolic adaptations of plants to stress alter their physiology (Bohnert et al., 1998), and affect plant development at the same time. Therefore, the CBL-CIPK

network connects plant growth and stress adaptations by modulating correlated physiological processes, including mediating phytohormone signals (Guo et al., 2002; Pandey, 2005; Song et al., 2005; Pandey et al., 2008) and regulating the homeostasis of sugar and various ions (Ma et al., 2019a; Ma et al., 2019b; Dong et al., 2021).

3.1 Phytohormone-related plant development and stress adaptation connected by CBL-CIPK network

Phytohormones are central regulators of plant growth and stress response. ABSCISIC ACID (ABA) stimulates dormancy during seed maturation (Sano and Marion-Poll, 2021), and also accumulates under osmotic stress to promote stomatal closure and reduce water loss (Luan, 2002). It has been reported that the CBL-CIPK network affects ABA-regulated plant development and abiotic stress response.

ABSCISIC ACID REPRESSOR 1 (*ABR1*) is a repressor of the ABA response because disruption of *ABR1* leads to a hypersensitive response to ABA in seed germination (Pandey, 2005). The AtCBL9-AtCIPK3 complex was found to activate *ABR1* in the nucleus, suppressing ABA-dependent dormancy and stimulating seed germination (Figure 2A) (Pandey, 2005; Pandey et al., 2008; Sanyal et al., 2017b). When treated with ABA or under osmotic stress, *At-cbl9*, *At-cipk3*, *At-cbl9cipk3*, and *At-abr1* mutants all showed reduced germination frequency but also impaired early seedling development (Pandey, 2005; Pandey et al., 2008). The germination impairment of these mutants under osmotic stress could be caused by the osmotic stress-induced increase in ABA levels. In addition, *At-abr1* adult seedlings exhibited smaller stomatal aperture after ABA treatment, which could be the reason why they had less water loss and showed a tolerant phenotype under drought stress (Sanyal et al., 2017b).

ETHYLENE RESPONSE FACTOR 7 (*AtERF7*) also represses the ABA response of plants. The RNAi-mediated suppression of *AtERF7* led to increased ABA sensitivity during seed germination, while the *AtERF7*-overexpressing lines had less stomatal

closure and higher sensitivity to drought stress than wild-type seedlings (Song et al., 2005). AtCIPK15 has been shown to phosphorylate AtERF7 and this may further repress the ABA response (Figure 2A) (Song et al., 2005). *At-cipk15* RNAi lines exhibited a series of ABA hypersensitivity phenotypes, including delayed seed germination, arrested early seedling development, and dramatically reduced stomatal pores and leaf transpiration (Guo et al., 2002; Song et al., 2005). The reduced water loss of the *At-cipk15* RNAi lines may also enhance its drought tolerance.

Figure 2 | Representative CBL-CIPK pathways involved in the crosstalk between plant development and stress adaptation. (A-C) CBL-CIPK pathways involved in phytohormone-related (A), ion homeostasis-related (B), and sucrose homeostasis-related (C) crosstalk between plant development and stress adaptation. Black pointed and blunt arrowheads indicate activating and inhibitory processes, respectively. The dotted lines indicate proposed processes. The green color in the text indicates plant development processes, while the red color in the text indicates plant stress responses.

3.2 Ion homeostasis-related plant development and stress adaptation connected by CBL-CIPK network

2

Bioinformatic analysis showed that the algal CIPKs are likely to be the closest orthologs of AtCIPK24, a key regulator of Na⁺ homeostasis when interacting with AtCBL4 (Kleist et al., 2014; Edel and Kudla, 2015). All CIPKs from *Physcomitrium patens* and *Selaginella moellendorffii* are orthologs of AtCIPK24 and AtCIPK23 (Weinl et al., 2009). AtCIPK23 is a key regulator of K⁺ homeostasis when interacting with AtCBL1 and AtCBL9 (Xu et al., 2006). In addition, algal CBLs feature the dual-lipid modification motif (or relicts of this motif) MGCXXS/T that presents in *Arabidopsis* AtCBL1/AtCBL9/AtCBL4 for PM localization (Kleist et al., 2014). This indicates that the ancestral role of the CBL-CIPK network is linked to the regulation of ion transport across the PM (Weinl et al., 2009; Kleist et al., 2014; Edel and Kudla, 2015).

From lower to higher plants, the number and complexity of CBLs and CIPKs increase (Weinl et al., 2009; Kleist et al., 2014), but the physiological functions of most CBL-CIPK pathways are still linked to ion homeostasis regulation (Dong et al., 2021). As the regulation of ion transport and homeostasis is essential in growth, development, as well as adaptation to stress conditions, it is not unexpected that the adaptation of ion transport regulated by CBL-CIPK pathways in stress response affects plant growth and development, and vice versa.

Ion homeostasis regulated by the CBL1/CBL9-CIPK23 pathway

Potassium (K⁺) is a vital nutrient that affects many biochemical and physiological processes in plants. K⁺ not only regulates plant growth and metabolism, but also contributes greatly to plant defense against various stresses (Wang et al., 2013).

The CBL1/CBL9-CIPK23-AKT1 pathway connects K⁺ homeostasis to plant growth, which is conserved in several plant species. CBL1 and CBL9 are two CBL proteins that have strong sequence similarity and have functional redundancy in ion uptake and transport. In *Arabidopsis*, AtCBL1/AtCBL9-AtCIPK23 complexes are important

positive regulators of root K^+ uptake through phosphorylation of K^+ transport systems HAK5 or AKT1 under different external K^+ concentrations (Xu et al., 2006; Aleman et al., 2011; Ragel et al., 2015). Leaf development and growth of *At-cbl1cbl9* double mutant, *At-cipk23* mutant, and *At-akt1* mutant were extremely impaired under K^+ deficiency (Figure 2B) (Xu et al., 2006). Rice (*Oryza sativa*) *OsCIPK23* RNAi lines and *Os-akt1* mutant showed similar K^+ -deficient symptoms under low K^+ conditions, including reduced K^+ content, leaf brown spots, and growth inhibition (Li et al., 2014). In addition, *OsCIPK23* RNAi lines had irregularly shaped pollen grains without any starch granules, which is typical for rice sterile pollen and may be related to impaired K^+ loading ability into the pollen (Yang et al., 2008). In grapevine (*Vitis vinifera*), the VvCBL1-VvCIPK4 complex (homologs of AtCBL1-AtCIPK23 complex) can activate the AKT1 ortholog VvK1.2, potentially mediating whole plant K^+ transport and translocation in fleshy fruit development (Cuellar et al., 2010; Cuellar et al., 2013). A dysfunctional SICBL1/SICBL9-SICIPK23-LKT1 (AKT1 ortholog) pathway in tomato (*Solanum lycopersicum*) did not affect growth, but the tomato *lkt1* mutant displayed sensitivity to excessive Mg^{2+} with chlorosis at leaf margins (Amo et al., 2021). This may be linked to impaired K^+ accumulation in the cytosol (Amo et al., 2021): Mg^{2+} is preferentially stored in vacuoles (Shaul, 2002), and impaired K^+ loading may affect the osmotic adjustment that compensates for the increased osmotic pressure in the vacuole caused by the accumulation of metal ions (Wang et al., 2013).

The K^+ nutritional status of plants affects their drought tolerance by regulating stomatal aperture, osmotic adjustment, and REACTIVE OXYGEN SPECIES (ROS) scavenging (Wang et al., 2013). AtCBL1/AtCBL9-AtCIPK23 complexes activate AKT1 and increase K^+ influx from leaf apoplast to guard cells, leading to stomatal opening and increased leaf transpiration (Figure 2B) (Cheong et al., 2007; Nieves-Cordones et al., 2012). Mutants with a disabled AtCBL1/AtCBL9-AtCIPK23-AKT1 pathway had decreased stomatal opening, which contributes to drought tolerance (Cheong et al., 2007; Nieves-Cordones et al., 2012). In addition, the NO_3^- transporter CHLORATE RESISTANT 1 (CHL1) is also activated by the AtCBL1/AtCBL9-

AtCIPK23 complexes, switching on high-affinity nitrate transport under low external NO_3^- concentrations (Liu and Tsay, 2003; Ho et al., 2009; Leran et al., 2015). The decreased nitrate accumulation in the guard cells may also contribute to stomatal closure and reduced transpiration rates in the mutants with a disabled AtCBL1/AtCBL9-AtCIPK23-AKT1 pathway. Indeed, there is evidence for enhanced drought tolerance in *At-chl1* mutants, with reduced stomatal opening and transpiration rates (Guo et al., 2003). It should be noted that the behavior of mutants with an impaired CBL1/CBL9-CIPK23 pathway under drought stress may vary between plant species. For instance, the *OsCIPK23* RNAi lines with reduced *OsCIPK23* expression were more sensitive to drought stress compared to wild-type plants rather than more tolerant, which is different from the phenotype of *At-cipk23* (Cheong et al., 2007; Yang et al., 2008). Possibly, the K^+ deficiency of *OsCIPK23* RNAi lines negatively affected their ability for osmotic adjustment or ROS detoxification.

Ion homeostasis regulated by the CBL4-CIPK6 pathway

Regulation of K^+ homeostasis also affects disease infection by inducing the synthesis of molecules like ROS and phytohormones (Ashley et al., 2006; Amtmann et al., 2008). AKT2 is a phloem-expressed weakly rectifying K^+ channel that is active in a wide membrane potential range and can mediate both influx and efflux of K^+ (Lacombe et al., 2000). The AtCBL4-AtCIPK6 complex regulates K^+ allocation by modulating the activity of AKT2 for both K^+ loading in the source and unloading in the sink (Figure 2B) (Lacombe et al., 2000; Held et al., 2011). *At-cipk6* mutants had enhanced disease resistance with increased ROS production and SA accumulation compared to wild-type plants after the infection of the bacterial pathogen *Pseudomonas syringae* pv. *tomato* DC3000 (Sardar et al., 2017). Increased ROS production and SA accumulation in *At-cipk6* mutants may be caused by disruption of the AtCBL4-AtCIPK6 regulated K^+ transport and allocation.

Different from the general activation mechanism of CBL-CIPK, the activation of AKT2 is dependent on the interaction but not the phosphorylation by the AtCBL4-AtCIPK6

complex. AKT2 is activated when it is translocated from the endoplasmic reticulum to PM and this translocation depends on AtCBL4 (Held et al., 2011). Aberrant K⁺ transport and allocation in the *At-cbl4*, *At-cipk6*, and *At-akt2* mutants were accompanied by reduced rosette size and delayed flowering phenotypes (Held et al., 2011). The *At-cipk6* mutants also had a remarkably decreased shoot-to-root and root basipetal auxin transport, resulting in fused cotyledons, swollen hypocotyls, and compromised lateral root growth (Tripathi et al., 2009).

Ion homeostasis regulated by CBL2/CBL3-CIPK3/CIPK9/CIPK23/CIPK26 pathway

Vacuolar ion homeostasis affects ion compartmentalization, vacuole inflation, and polar growth, which are required for multiple physiological processes in plant development and stress adaptation, including metal ionic tolerance, stomatal movement, pollen germination, and polarized pollen tube growth.

Tonoplast-localized AtCBL2 and AtCBL3, another two partly functionally redundant CBLs, work as crucial regulators of vacuolar ion homeostasis. Ion compartmentalization of *At-cbl2cbl3* double mutant was affected, thus its abilities of ionic tolerance (to excessive Ca²⁺, Fe³⁺, Cu²⁺, K⁺, and Zn³⁺) and micronutrient storage (of Ca²⁺, Mg²⁺, Mn²⁺, Fe³⁺) were compromised (Tang et al., 2012). It was suggested that AtCBL2 and AtCBL3 positively regulate the activity of vacuolar H⁺-ATPase (V-ATPase) (Figure 2B) (Tang et al., 2012), which is the major proton pump in establishing and maintaining an electrochemical proton gradient across the tonoplast to drive ion transport (Lüttge et al., 2001). However, a more recent study showed that AtCBL2 and AtCBL3 regulate Mg²⁺ compartmentalization together with multiple AtCIPKs (AtCIPK3/AtCIPK9/AtCIPK23/AtCIPK26) through a V-ATPase-independent pathway (Figure 2B) (Tang et al., 2015), indicating that AtCBL2 and AtCBL3 regulate ion homeostasis through several different downstream pathways. Recently, more pathways under the control of AtCBL2 and AtCBL3 were discovered: AtCBL2/AtCBL3-AtCIPK3/AtCIPK9/AtCIPK26 negatively regulates the transport activity of vacuolar Mn²⁺ transporter AtMTP8, inhibiting Mn²⁺ transport from the cytoplasm to the vacuole (Ju et al., 2022).

In addition, AtCBL2/AtCBL3-AtCIPK3/AtCIPK9/AtCIPK23/AtCIPK26 complexes were found to activate the vacuolar two-pore K⁺ channels AtTPKs for K⁺ remobilization to the cytoplasm under low-K⁺ stress (Tang et al., 2020b), explaining why the *At-cbl2cbl3* double mutants retain more K⁺ even though they showed more sensitive to K⁺ deficiency than wild-type (Tang et al., 2012; Tang et al., 2020b). The mutation of *AtCIPK9* alone leads to a discernible vacuolar K⁺ conductance reduction and sensitivity to K⁺ deficiency, suggesting that *AtCIPK9* might be a dominating *AtCIPK* in the regulation of vacuolar K⁺ homeostasis (Tang et al., 2020b). The importance of *AtCIPK9* for vacuolar K⁺ homeostasis is exemplified by the study of Song et al. (2018), in which the *At-cipk9* mutant had reduced vacuolar K⁺ influx through K⁺/H⁺ antiporter AtNHX1 and AtNHX2 but not defective vacuolar K⁺ release through AtTPK1, resulting in ABA-hypersensitive stomatal closure and thus enhanced drought tolerance (Song et al., 2018).

Interestingly, Tang et al. (2012; 2020b) reported on contrasting phenotypes of the *At-cbl2cbl3* double mutant under low-K⁺ stress. In their earlier study, they reported *At-cbl2cbl3* double mutant was more tolerant than WT under low-K⁺ (50 μM, 100 μM, 200 μM) conditions (Tang et al., 2012), while they recently observed the *At-cbl2cbl3* double mutant was more sensitive than WT under low-K⁺ (10 μM, 100 μM) conditions (Tang et al., 2020b). The different NH₄⁺ concentrations used in root media (20 mM in the previous study and 1 mM in the recent study) were suggested as the cause for the contradicting phenotypes (Tang et al., 2020b), as NH₄⁺ toxicity might mask the true phenotype of mutants under low-K⁺ stress (Shi et al., 2020). It is well known that NH₄⁺ toxicity enhances the plant sensitivity to low-K⁺ stress while K⁺ relieves plant sensitivity to NH₄⁺ toxicity (Shi et al., 2020), while the *At-cbl2cbl3* double mutant exhibited a more tolerant phenotype than the wild-type under the more severe combined stress conditions (low-K⁺ and high NH₄⁺), suggesting that AtCBL2 and AtCBL3 might also be involved in the regulation of NH₄⁺ homeostasis. For another study, however, *At-cbl3* and *At-cipk9* mutant were reported to be more tolerant than wild-type under K⁺ deficiency even when NH₄⁺ concentration in root media was as

low as 1.25 mM (Liu et al., 2013), indicating the possible role of CBL-CIPK network in regulating K^+ and NH_4^+ homeostasis is worth exploring in more detail.

Both *At-cbl2cbl3* double mutants and *At-cipk3/9/23/26* quadruple mutants were severely inhibited in growth (Tang et al., 2012; Tang et al., 2020b), and the *At-cbl2cbl3* double mutant also displayed leaf tip necrosis, underdeveloped roots, shorter siliques, fewer seeds, and defective embryonic development (Tang et al., 2012; Eckert et al., 2014), which are symptoms that may be related to micronutrient deficiency (e.g. Ca^{2+} , Mg^{2+} , Mn^{2+} , Fe^{3+}) or abnormal vacuolar K^+ homeostasis (Song et al., 2018; Tang et al., 2020b). In addition, *At-cbl2*, *At-cbl3*, *At-cbl2cbl3*, and *At-cipk12* mutant lines all showed dramatically reduced pollen germination rates and altered tonoplast morphologies in pollen tubes. This suggests that AtCBL2, AtCBL3, and AtCIPK12 play a role in maintaining vacuole inflation and polar growth, which is required for essential processes for reproduction like pollen germination, polarized tube growth, and vacuolar morphology (Steinhorst et al., 2015). This reproduction barrier in *At-cbl2*, *At-cbl3*, *At-cbl2cbl3*, and *At-cipk12* mutants therefore may also be resulting from abnormal vacuolar ion homeostasis in pollen.

3.3 Sugar homeostasis-related plant development and stress adaptation connected by CBL-CIPK network

Sugars are the main carbon- and energy-containing molecules needed for plant growth and development, and they are substrates for cell wall construction as well as cellular solutes for osmotic balance (Griffiths et al., 2016). Several CBL-CIPK complexes were shown to play roles in the phosphorylation of sugar transporters and regulation of sugar homeostasis. For example, cotton (*Gossypium hirsutum*) GhCBL2-GhCIPK6 was reported to promote sugar (glucose) accumulation via interaction with the tonoplast sugar transporter TONOPLAST SUGAR TRANSPORTER 2 (TST2) (Deng et al., 2020). The *GhCIPK6*-overexpressing lines had more energy for growth under starvation treatment (a 10-day dark treatment followed by a 3-day recovery period) compared to the wild-type that had a withering

phenotype (Deng et al., 2020).

In apple (*Malus domestica*), the overexpression of *SUCROSE TRANSPORTER 2.2* (*MdSUT2.2*) improves sucrose accumulation and tolerance to salt stress and drought stress (Ma et al., 2019a; Ma et al., 2019b). The enhanced salt and drought tolerance of *MdSUT2.2*-overexpressing apple seedlings were shown to be dependent on the phosphorylation of *MdSUT2.2* by *MdCIPK13* and *MdCIPK22*, respectively (Figure 2C) (Ma et al., 2019a; Ma et al., 2019b). In addition, the overexpression of *MdCIPK13* and *MdCIPK22* improved sugar accumulation, as well as the salt stress and drought stress tolerance of transgenic apple seedlings, respectively (Ma et al., 2019a; Ma et al., 2019b). This may be related to osmotic adjustment through increased sucrose accumulation in these *MdCIPK13*- and *MdCIPK22*- overexpressing apple seedlings in response to osmotic stress (Figure 2C) (Ma et al., 2019a; Ma et al., 2019b). Sugar content also influences fruit flavor, color, and other quality traits in apple. Transient overexpression of *MdCBL1* and *MdCIPK13* increased the sugar content of apple fruit, whereas transient suppression of these genes decreased the sugar content of apple fruit (Jiang et al., 2021). These are clear examples of the CBL-CIPK pathway regulating the response to salt and drought stress (through osmotic adjustment) while also affecting apple growth and fruit quality.

Sugar accumulation during cold acclimation may contribute to the stabilization of membranes, protecting plants from cold-induced cellular damage (Thomashow, 1999). In *Arabidopsis*, *AtCBL1* was predicted to regulate sugar metabolism by interacting with *AtCIPK7* to target sucrose synthase (Chikano et al., 2001; Huang et al., 2011). The *At-cbl1* mutant was sensitive to low temperature and exhibited much more severe wilting symptoms than the wild-type (Huang et al., 2011). The wilting symptoms of *At-cbl1* under cold stress may be related to cold-induced cellular damage caused by deficient sugar accumulation (Huang et al., 2011). More research needs to be done to confirm the involvement of *AtCBL1-AtCIPK7* in sugar metabolism during cold stress.

Soluble sugars are substrates for glycolysis, producing pyruvate that enables alcohol dehydrogenase (Adh) to reoxidize NADH to produce ATP under hypoxia conditions like flooding stress (Zabalza et al., 2009). Rice *OsCIPK15* is necessary for the expression of α -amylase genes (α Amy3, α Amy7, and α Amy8) and *Adh2* and the production of α -amylase and Adh under flooding stress, which are required for sugar production and fermentation (Lee et al., 2009). Energy deficiency of the *Os-cipk15* mutant leads to sensitivity to flooding stress at both the germination stage and seedling growth stage (Lee et al., 2009). Another further study showed that OsCBL4 is the partner of OsCIPK15 in regulating the expression of α Amy3 (also named *RAmy3D*) (Ho et al., 2017) (Figure 2C). Knowledge about the role of the CBL-CIPK network in sugar homeostasis is as yet limited, but it deserves more attention considering the important physiological roles of sugars in plant development and stress adaptation.

4 PROSPECTS: BREEDING STRATEGIES TARGETING COMPONENTS OF THE CBL-CIPK NETWORK

Developing crops with improved stress tolerance is a highly sustainable strategy to meet the food demand of an increasing human population. Genome-editing based on the CRISPR-Cas9 technique is regarded as a new plant breeding technology that can help achieve this goal. However, few genes have been successfully used for improving stress tolerance without yield penalties under normal conditions in field trials. One of the reasons is that the molecular regulatory networks of plant growth and stress tolerance are complicated and their crosstalk is poorly understood. The CBL-CIPK network is involved in both stress response and plant development, and components of this network can be a target for plant breeding. More detailed knowledge about how the CBL-CIPK network connects with other pathways can help us to better target and modulate the components in the CBL-CIPK network for breeding varieties with optimized stress tolerance and a minimal yield penalty.

The information presented in this review indicates that constitutive overexpression

or complete knockout of *CBL* and *CIPK* genes is likely to interrupt other signaling pathways and thus may lead to unwanted side effects. For example, the *At-cipk6* mutant exhibits enhanced disease resistance (Sardar et al., 2017), but the growth and development of the *At-cipk6* mutant are disrupted, showing reduced rosette size and later flowering (Held et al., 2011). In this case, an alternative approach would be to modify the gene expression or protein function rather than knocking out or constitutively overexpressing the gene.

4.1 Modify gene expression through promoter-editing

Gene promoter provides a rich source of targets for genome-editing, contributing to dissecting tradeoff effects in crop breeding (Song et al., 2022). The DNA double-strand break in the target locus generated through CRISPR-Cas9 genome editing can be repaired through the high-fidelity homology-directed repair, stimulating precise sequence alteration. Based on this, promoter fragment insertion and swap can be generated when a DNA repair template is exogenously supplied (Shi et al., 2017). This would enable fine-tuning the gene expression to a specific tissue, under a specific stress condition, or at a specific developmental stage to reduce the trade-off between disease defense and growth.

The promoter of a gene can be replaced with a tissue-specific driving promoter. For instance, with a phloem-specific expression, *AtCIPK6* is still able to regulate the activity of phloem-expressed AKT2 to ensure the K⁺ nutrition for plant growth, and the loss of *AtCIPK6* in leaves will increase resistance to the pathogen infection. This effectively uncouples the tradeoff between plant growth and disease response connected by *AtCIPK6*. In some cases, *cis*-regulatory elements in a promoter can be deleted through CRISPR-Cas9 to alter the tissue-specific gene expression by avoiding the inhibition of tissue-specific expressed transcription factors, thus uncoupling linkage traits (Song et al., 2022).

In addition, stress-inducible promoters can also be used so that the gene is highly expressed only under specific stress without yield loss under normal conditions (Pino

et al., 2007). For example, AtCBL2 and AtCBL3 positively regulate plant tolerance to Mg^{2+} toxicity (Tang et al., 2015), but their overexpression interferes with pollen germination and tube growth (Steinhorst et al., 2015). In this case, an Mg^{2+} toxicity-inducible promoter with a higher driving activity under Mg^{2+} toxicity stress will help to resolve this tradeoff. Another alternative approach would be to insert Mg^{2+} toxicity-responsive *cis*-regulatory elements in the native promoter of *AtCBL2* and *AtCBL3*.

4.2 Fine-tune protein function through gene-editing

Generating single-nucleotide polymorphism (SNP) is able to modify a protein function, which could be another way to reduce the growth-defense tradeoff. A reference case is about RESISTANCE OF RICE TO DISEASES1 (ROD1), which is a Ca^{2+} sensor that can scavenge ROS by stimulating catalase activity and thus suppress rice immunity (Gao et al., 2021). ROD1 inhibits ROS production under normal conditions to avoid the growth penalty, while it was degraded upon pathogen infection to ensure proper plant defense. Therefore, constitutively activated immunity in *rod1* mutants increased the pathogen resistance but compromised plant growth, leading to reduced grain yield (Gao et al., 2021). The researchers found that a natural SNP mutation of *ROD1* attenuated its ROS scavenging ability, contributing to improved basal defense without yield penalty (Gao et al., 2021). In this theory, inducing targeted mutations can potentially attenuate the protein kinase activity of AtCIPK6, retaining basal defense and plant growth at the same time.

4.3 Modify the expression of splice variants

Alternative splicing (AS) of genes is a key regulatory mechanism for plants to adapt to the environment (Rigo et al., 2019). The analysis of genome sequencing results has shown that AS-induced splice variants widely exist in *CBL* and *CIPK* families (Kolukisaoglu et al., 2004; Kanwar et al., 2014; Hu et al., 2015). It was reported that splice variants of *AtCIPK3* showed transcript and interaction preference (Sanyal et al., 2017a), which may lead to different expression patterns, protein kinase activity, and downstream targets. The splice variants of some *CBLs* (eg. *AtCBL4*) may have

different protein localization and interactors because of the difference in the N-terminus and EF domain of their encoded proteins (Figure S1). AS of CBL-CIPK components could play roles in the crosstalk between growth and defense, thus overexpressing or knocking out a specific splice variant could be another possibility to tune the gene function and relieve the growth-defense tradeoff.

In summary, to take optimal advantage of these powerful strategies to target the CBL-CIPK network, advanced knowledge about the roles of the CBL-CIPK network and its crosstalk with other pathways is essential. With more research and deeper insight into the physiological roles of splice variants of these genes, the potential for the moderation of CBL-CIPK gene functions may be exploited in the future for breeding climate-proof crop varieties.

CONFLICT OF INTEREST STATEMENT

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

AUTHOR CONTRIBUTIONS

J.M. conceived the original writing plans; J.M., C.G.V.L., and Q.W. completed the writing; H.L., Q.W., and C.G.V.L. co-supervised the writing; Z.M., Y.G., and H.X. provided ideas and joined discussion; R.G.F.V. and Y.B. helped with manuscript revision. H.L. and Q.W. agree to serve as the authors responsible for contact and ensure communication. All authors contributed to the article and approved the submitted version.

FUNDING

This work was supported by the National Natural Science Foundation of China (32170387), International Foundation of Tobacco Research Institute of CAAS (IFT202102), Key Funding of CNTC (No. 110202101035(JY-12)) and YNTI (No. 2020JC03, 2022JY03), China Scholarships Council (CSC No. 201803250083), and

International Exchange Scholarship of the GSCAAS.

ABSTRACT

The *CALCINEURIN B-LIKE PROTEIN* family genes (*CBLs*) encode a group of plant-specific calcium sensor proteins that play critical roles in plant development and stress response. Although genome-wide analysis of *CBL* family genes has been conducted in several diploid plant species, less is known about their functions in allopolyploid plant species. This study conducted a detailed analysis of tobacco *CBL* family genes. Of the 24 *NtCBL* genes identified, 14 were derived from the maternal genome donor *N. sylvestris*, and 10 were from the paternal genome donor *N. tomentosiformis*. Phylogenetic analysis revealed that *NtCBLs* could be clustered into three different groups with distinct N-terminal characteristics. All *NtCBLs* contain EF-hand motifs, but amino acid substitutions and configuration changes may be responsible for variations in their Ca^{2+} -binding abilities. Alternative splicing is common for *NtCBL* gene transcripts, which may contribute to variations in translation efficiency or protein interaction preferences. Several *NtCBL* genes exhibited shoot- or root-predominant expression patterns, and some were responsive to salt and/or drought stress. *NtCBL4A-1*, an ortholog of *Arabidopsis thaliana AtCBL4* (SOS3), was predominantly expressed in roots and exhibited a lower gene expression level under salt stress. Further functional analysis showed that overexpression of *NtCBL4A-1* increased the sensitivity of transgenic tobacco to Na^{+} -induced salt stress, which is inconsistent with the role of *AtCBL4* in contributing to salt tolerance. This study provides data for identifying *CBL* gene functions and selecting candidate stress-tolerant genes in *N. tabacum*. Additionally, the results may aid gene function studies in other allopolyploid plant species.

Keywords: tobacco; CBL; EF-hand; splicing variants; gene expression; salt stress; drought stress

INTRODUCTION

Climate change directly impedes crop production by affecting water availability and weather extremes (Kang et al., 2009; Reynolds, 2010), and indirectly impedes crop production by affecting other species such as pollinators, pests, disease vectors, and invasive species (Liliane and Charles, 2020). Moreover, crops are often subjected to a combination of different stresses in the field (Mittler, 2006). It is therefore of the utmost importance that crops are able to adapt to these changing conditions, and maintain high yields even under adverse growing conditions. Dissection of abiotic stress sensing and signaling networks and the downstream adjustments in metabolism and development continues to provide knowledge that contributes to solutions for crop improvement (Vanderschuren et al., 2013; Brozynska et al., 2016).

The CALCINEURIN B-LIKE PROTEIN (*CBL*) family genes encode plant-specific Ca^{2+} sensor proteins that interpret and relay intracellular Ca^{2+} signals triggered by external stimuli. CBL proteins transmit various Ca^{2+} signals during plant development and in response to stress by interacting with different CBL-INTERACTING PROTEIN KINASE PROTEINs (CIPKs) to evoke downstream responses (Luan, 2009). CBL proteins detect and recognize the Ca^{2+} signals using the Ca^{2+} -binding EF-hand (Shanker and Venkateswarlu, 2011; Sánchez-Barrena et al., 2013). When CBLs bind Ca^{2+} , their molecular surface properties are modified, enabling interaction with the NAF domain (named for its highly conserved amino acids Asn (N), Ala (A), and Phe (F)) of CIPK proteins (Sánchez-Barrena et al., 2013). CIPK proteins are subsequently activated to phosphorylate downstream targets such as ion transporters and enzymes involved in plant development and the stress response (Guo et al., 2001; Nunez-Ramirez et al., 2012; Sánchez-Barrena et al., 2013).

The typical structure of CBL proteins includes four EF-hands composed of two α -helixes and an intervening loop that resembles a right hand with the thumb (F-helix) and the forefinger (E-helix) extended at 90° (Kretsinger and Nockolds, 1973; Batistic and Kudla, 2009; Sánchez-Barrena et al., 2013). The subcellular location of the CBLs partially depends on motifs in their N-terminus (Kleist et al., 2014). CBL

proteins whose N-termini harbor a dual lipid modification motif can be anchored to the plasma membrane (PM) (Batistic et al., 2008; Held et al., 2011; Saito et al., 2018). CBL proteins harboring a conserved tonoplast targeting sequence (TTS) are generally tonoplast-targeted (Batistic et al., 2012). CBL10 is a special CBL protein that contains a transmembrane helix in its N-terminus, so that it can be localized to both PM and tonoplast (Kleist et al., 2014). The FPSF domain in the C-termini of CBL proteins is another conserved motif containing a Ser (S) residue, which is the phosphorylation target of CIPKs (Hashimoto et al., 2012). The phosphorylation status of CBLs affects the stability of some CBL-CIPK complexes, such as AtCBL10-AtCIPK24 and AtCBL1/9-AtCIPK23, but not AtCBL4-AtCIPK24 (Hashimoto et al., 2012).

One CBL may interact with different CIPKs, and vice versa. Thus, CBLs and CIPKs form an intricate CBL-CIPK signaling network. The prototype of the CBL-CIPK signaling modules dates back to single-cell green algae, in which only one single CBL-CIPK signaling module exists (Weinl and Kudla, 2009; Kleist et al., 2014). The ancestral function of CBL-CIPK signaling module is likely to regulate ion homeostasis (Kleist et al., 2014). The number of CBL and CIPK members expanded from lower plants to higher plants (Kleist et al., 2014). CBL and CIPK members have been widely identified in many plant species and most extensively studied in *Arabidopsis thaliana*. The key roles of identified CBLs in plant development and stress response indicate that CBL family genes may have great potential as targets for crop stress tolerance improvement (Mao et al., 2022).

The genome-wide analysis of CBL family genes has been conducted in several plant species, including *Arabidopsis*, rice, pineapple, tea, apple, turnip, and grapevine (Kolukisaoglu et al., 2004; Xi et al., 2017; Yin et al., 2017; Aslam et al., 2019; Liu et al., 2019; Chen et al., 2021). However, this analysis has been rarely done for allopolyploid species. In allopolyploid plants, the expression of genes from the homoeologous chromosomes needs to be orchestrated to enable the parental genomes to coexist harmoniously and contribute to growth vigor and broader

phenotypic diversity (Feldman and Levy, 2009; Akhunova et al., 2010). Homoeologs, the 'corresponding' genes derived from different species in an allopolyploid (Glover et al., 2016), may have redundant or different functions depending on their sequence similarity and expression profile. This makes the functional characterization of a specific gene in allopolyploidy more complicated. Researchers must consider the functional relevance and dominance of homoeologs when deciding whether to knock out all the homoeologs together when constructing mutants. In most cases, it is more efficient to construct both the single mutant and the double/multiple mutant. Without considering these factors, it is very likely that the single mutant appears relatively normal or exhibits only a mild phenotype because of redundancy/compensation (Peng, 2019), with no evidence that the gene is non-functional or less functional. Therefore, a detailed overview of family genes at the level of individual homoeologs in allopolyploidy is helpful, particularly in the design and interpretation of forward and reverse genetic functional studies.

Cultivated tobacco (*Nicotiana tabacum*) is a typical allotetraploid species that is derived from the maternal genome donor *N. sylvestris* and the paternal genome donor *N. tomentosiformis* (Murad et al., 2002; Yukawa et al., 2006). The functional identification and characterization of *CBL* genes in *N. tabacum* are scarce. The only report shows that overexpression of *NtCBL5A* increases the salt sensitivity of transgenic tobacco (Mao et al., 2021). This study provides a detailed analysis of individual *NtCBL* homoeologs. It includes identification and structural analysis of *NtCBL* family members, prediction of subcellular localization and Ca^{2+} -binding ability of *NtCBL* proteins, identification of key amino acid sites for the functions of *NtCBL* proteins, examination of gene structure and splicing variants (contributing to variation in translation efficiency or preference of protein interaction) of *NtCBL* genes at the level of individual homoeologs. In addition, this study investigates the expression profiles of *NtCBL* genes in different tissues, at different developmental stages, as well as under salt and drought stresses. *NtCBL4A-1*, an ortholog of *AtCBL4* (SOS3) that was identified as a key component in plant salt stress response, was identified as responsive to salt stress and studied in more detail. This study

provides insight into the *NtCBL* family genes and the *NtCBL* gene homoeologs from the two parental genomes, serving as a guide for further detailed functional characterization of individual *NtCBL* family genes.

MATERIALS AND METHODS

Identification of NtCBL genes

The amino acid sequences of ten *Arabidopsis* CBL genes were obtained from the TAIR database (<https://www.arabidopsis.org/>). Using these sequences as queries, the *NtCBL* protein sequences from the *N. tabacum* genome were identified in the NCBI database (<https://www.ncbi.nlm.nih.gov/>) with the BLASTP method (E-value cutoff was $1e^{-5}$). Redundant entries resulting from alternative splicing were manually removed, and the remaining sequences were used as new queries for a second BLASTP search. After sequence alignment and SMART analysis (<http://smart.embl-heidelberg.de/>), sequences lacking CBL-specific motifs were removed. The ExPASy tool (<https://web.expasy.org/protparam/>) was used to calculate the molecular weight, isoelectric point, and amino acid number of the identified proteins.

Classification of NtCBL genes

To classify the *NtCBLs*, *AtCBL* and *NtCBL* protein sequences were used in the phylogenetic analysis. The phylogenetic tree was constructed using the Neighbor-Joining method with default parameters in MEGA6 (bootstrap replicates=1000). Multi-sequence alignment was conducted using Clustal Omega (<https://www.ebi.ac.uk/Tools/msa/clustalo/>) and the result was presented by GeneDoc (Nicholas, 1997).

Prediction of conserved motifs and analysis of 3D protein structure

The conserved motifs of *NtCBLs* were predicted using SMART (<http://smart.embl-heidelberg.de/>) (Letunic et al., 2021). The 3D protein structures of *NtCBLs* were predicted with SWISS-MODEL (<https://swissmodel.expasy.org/>) (Waterhouse et al., 2018). The EF-hand backbones and potential Ca^{2+} -binding sites were visualized using Swiss-Pdb Viewer (Guex and Peitsch, 1997).

Analysis of cis-acting elements in the promoter of NtCBL genes

To find *cis*-acting elements localized in the promoter region of *NtCBL* genes, 3000 bp of promoter regions upstream of the 5'-UTR of *NtCBL* genes were queried. The *cis*-acting elements were predicted by PlantCARE (<http://bioinformatics.psb.ugent.be/webtools/plantcare/html/>) (Rombauts et al., 1999) and presented with a heatmap by Tbtools (Chen et al., 2020).

Plant materials, growth conditions, and application of salt and drought treatment

N. tabacum L. cv. Zhongyan 100 cultivar was used as plant material in this study. For determining the expression profiles of *NtCBL* genes in different tobacco tissues at a young stage, tobacco plants were grown in 2019 at Unifarm, Wageningen University & Research in the Netherlands. The conditions of the greenhouse were 16 h light / 8 h dark at 25/23°C and 70% relative humidity. The shortwave radiation level was maintained in the greenhouse compartment using artificial PAR (photosynthetically active radiation) when the incoming shortwave radiation was below 200 Wm⁻² (Mao et al., 2021). Tobacco seeds were first sown in the soil. At 20 days after germination (DAG), the young tobacco plants were transplanted in rock-wool plugs within float trays for hydroponic cultivation (1/2 Hoagland's nutrient solution). After 6 days of acclimatization (at ~30 DAG), different tissues (leaf blades: all leaves with main veins removed; main veins: main veins from all leaves; stems; roots) of young tobacco plants were sampled at 35 DAG and frozen in liquid nitrogen.

For determining the expression profiles of *NtCBL* genes under salt and drought stresses, tobacco plants were grown in 2022 at the Tobacco Research Institute of the Chinese Academy of Agricultural Sciences in China. The climate chamber was set to maintain 24 h lighting (with an intensity of 7500 lux) at a temperature of 25°C and 70% relative humidity. Tobacco seeds were initially sown in the soil, and for the salt treatment, young tobacco plants were transplanted into rock-wool plugs within float trays for hydroponic cultivation (1/2 Hoagland's nutrient solution) at 20 DAG. After a period of 6 days of acclimatization (at ~30 DAG), the nutrient solution was supplemented with NaCl to a concentration of 50 mM on the first day to avoid salt

shock, with the final NaCl concentration of 100 mM being achieved on the following day.

At 1 day after the start of 100 mM NaCl treatment, leaves from both the control and salt-stressed plants were sampled and immediately frozen in liquid nitrogen. For the drought treatment, young tobacco plants were transplanted into pots at 24 DAG. After 6 days of acclimatization (at ~30 DAG), watering was stopped until the leaves began to show slight wilting. At 5 days after the start of the treatment, leaves from both the control and drought-stressed plants were sampled and immediately frozen in liquid nitrogen.

Real-time quantitative PCR

Total RNA was extracted from tissues of young tobacco plant tissues using the RNeasy Plus Mini Kit (Qiagen, Cat No./ID: 74134) and purified according to the manufacturer's protocol. The RT-qPCR protocol used was described by Mao et al. (2021). RNA was reverse transcribed into cDNA using Evo M-MLV Mix Kit with gDNA Clean for qPCR (Accurate Biotechnology (Hunan) Co., Ltd, Cat No./ID: AG11728, Changsha, China), and the cDNA was amplified using SYBR Green *Pro Taq* HS qPCR Premix (Accurate Biotechnology (Hunan) Co., Ltd, Cat No./ID: AG11701, Changsha, China) on the LightCycler® 96 Instrument (F. Hoffmann-La Roche Ltd, Switzerland). All the primers used for RT-qPCR are listed in Table S1. Amplification reactions were carried out in a total volume of 10 µl, containing 5 µl 2×SYBR Green *Pro Taq* HS qPCR Premix, 0.6 µl forward and reverse primers (10 µM), 1 µl cDNA (10 times diluted), and 3.4 µl ddH₂O. The RT-qPCR amplification program was as follows: 95°C for 10 min, followed by 40 cycles of amplification at 95°C for 10 s, 60°C for 30 s. Relative gene expression data were analyzed using the 2^{-ΔC_t} method (Livak and Schmittgen, 2001).

Generation of NtCBL4A-1-OE plants

The coding sequence of *NtCBL4A-1* (NCBI reference sequence: XM_016613931.1) was first amplified from cDNA synthesized from RNA extracted from roots of *N. tabacum* L. cv. Zhongyan 100 with the primer pair NtCBL4A-1F/NtCBL4A-1R (Table

S1). The *NtCBL4A-1* cDNA was firstly cloned into the pMD19-T vector for sequencing and then was amplified with primer pair NtCBL4A-1F-*Kpn* I /NtCBL4A-1R-*Xba* I (Table S1). The gel-purified amplicon was digested with *Kpn* I and *Xba* I and cloned into the binary recombinant vector pCHF3 to generate the vector pCHF3-NtCBL4A-1. To generate the *NtCBL4A-1*-overexpressing lines, pCHF3-NtCBL4A-1 plasmid was transformed into *Agrobacterium tumefaciens* EHA105 and then was introduced into Zhongyan 100 by the *Agrobacterium*-mediated leaf disc transformation method (Horsch et al., 1985).

Nine positive transgenic plants of the T0 generation were identified by PCR with the primers pCHF3-62F and NtCBL4A-1R (Table S1). The expression of endogenous *NtCBL4A-1* was determined by RT-qPCR with the primer pair NtCBL4-qF/NtCBL4A-1qR, and the expression of exogenous *NtCBL4A-1* was determined by using the primers NtCBL4A-1-qF and pCHF3-Allcheck-2 (Shi et al., 2021). Six lines with high *NtCBL4A-1* overexpression were selected for propagation. The screening strategy of homozygous plants was mentioned in our previous publication (Mao et al., 2021). Two independent homozygous lines (OE-2 and OE-9) were selected for the evaluation of stress tolerance. The ion and osmotic stress evaluation of different tobacco lines were conducted as previously described (Mao et al., 2021).

RNAseq data expression analysis

Expression profiles of *NtCBL* genes in leaves (SRA accession ID: SRX2655430, SRX2655478, SRX2655480, SRX2655632, SRX2655633, SRX2655634) and roots (SRA accession ID: SRX4407884, SRX4407877, SRX4407878) of tobacco at the adult stage were analyzed from published RNA-seq data (Li et al., 2017; Qin et al., 2020).

Statistical analysis

Statistical analysis was done using IBM SPSS Statistics 23 software. Significant differences were examined by Student's *t* test or one-way ANOVA with LSD test at $p < 0.05$ and $p < 0.01$. The figures were drawn by GraphPad Prism 6.0.

RESULTS AND DISCUSSION

Identification and designation of *NtCBLs*

The protein sequences of ten *A. thaliana* *AtCBLs* were used as queries to identify *NtCBL* genes in the *N. tabacum* genome in the NCBI database (<https://www.ncbi.nlm.nih.gov/>). Twenty-four *NtCBL* gene loci were found in total. Generally, these *NtCBLs* were numbered based on the names of the most similar *AtCBL* genes (Figure 1A, Table 1). *NtCBL6* is an exception because it does not have close homologs in *Arabidopsis* (a detailed explanation is provided in section 3.4). It was numbered as “6” because that was the only unoccupied number from “1” to “10”. Of the 24 *NtCBLs* analyzed, 15 showed the greatest sequence similarity to the *CBLs* of the maternal tobacco progenitor *N. sylvestris*, and were therefore labeled as “A”. The remaining 9 *NtCBLs* were more similar to *CBLs* of the paternal tobacco progenitor *N. tomentosiformis*, and were labeled as “B” (Mao et al., 2021). *NtCBLs* with the highest similarity to the same *AtCBL* protein were numerically ordered. For example, the three *NtCBL* genes that were found to be most similar to *AtCBL1* were named *NtCBL1A-1*, *NtCBL1A-2*, and *NtCBL1A-3*. (Figure 1A, Table 1). For brevity, we refer in this paper to all the homoeologous genes of one specific *NtCBL* when “A” or “B” is not specially indicated.

The number of amino acids (AA), theoretical isoelectric point (pI), and molecular weight (MW) of the *NtCBLs* are listed in Table 1. Some *NtCBL* genes (*NtCBL2/4A-1/4A-2/5/9B*) encode splicing variants that are translated into proteins of different lengths. For these, one encoded protein was selected as a representative. More information about other variants is provided in section 3.4. The amino acid number of the 24 *NtCBLs* ranged from 210 to 260, with MW ranging from 23.79 kDa to 30.00 kDa, and pI ranging from 4.57 to 5.20. The sequence alignment shows that all the *NtCBLs* have four EF-hands and an FPSF domain (named by its highly conserved amino acids Phe (F), Pro (P), Ser (S), and Phe (F)), but vary in length at their N-terminal sides (Figure S1).

Table 1 Properties of *NtCBLs*

AA, the number of amino acids; pI, theoretical isoelectric point; MW, molecular weights. The AA, pI, and MW were calculated with the ExPASy tool (<https://web.expasy.org/protparam/>).

Figure 1. Phylogenetic tree and N-terminal sequence alignments of the NtCBLs and AtCBLs. (A) Phylogenetic analysis of NtCBLs and AtCBLs. The amino acid sequences of AtCBLs were downloaded from TAIR (<https://www.arabidopsis.org/>). The phylogenetic tree was constructed by MEGA6 using the Neighbor-Joining method. **(B-D)** N-terminal sequence alignments of the NtCBLs and AtCBLs. The key Cys (C) residues in CBLs for S-acylation and the key Gly (G) residue in CBLs for N-myristoylation were marked with hollow dots and full dots, respectively. The numbers above these dots mean the positions of these residues in the amino acid sequences of the first CBLs. The hydrophilic and hydrophobic amino acids in panel D were shaded with blue and pink, respectively.

Classification and subcellular localization analysis of NtCBLs

Similar to AtCBLs (Kleist et al., 2014), NtCBLs are classified into three types based on the phylogenetic analysis and the characteristics of their N-terminal sequences (Figure 1). The N-terminal motif is critical for the subcellular localization of CBLs (Kleist et al., 2014), and CBLs often affect the function of CIPKs by recruiting CIPKs

to specific subcellular locations (Luan, 2009).

Type I includes 15 NtCBL members (Figure 1A, Table 1) that are the orthologs of AtCBL1/4/5/8/9. Most of them contain the dual lipid modification motif (MGCXXS/T) for *N*-myristoylation at the Gly residue (G at position 2) and *S*-acylation of the Cys residue (C at position 3) in their N-terminal regions (Figure 1B). NtCBL1/4/5/9 have the same G and C residues for dual lipid modification that ensures the plasma membrane (PM) localization of AtCBL1/4/5/9 (Batistic et al., 2008; Held et al., 2011; Saito et al., 2018), suggesting that these NtCBLs might be associated to the PM as well. It needs to be noted that the N-terminal dual lipid modification of CBLs is not a PM-specific localization signal, because AtCBL4 and AtCBL5 are also distributed in the cytoplasm and nucleus (Batistic et al., 2010). The subcellular localization of NtCBL8A-1, NtCBL8A-2, NtCBL8B-1, and NtCBL8B-2 might have different subcellular localization from those of other NtCBLs in type I, because none of them has the C residue (position 3) and NtCBL8A-2 and NtCBL8B-2 do not have the G residue (position 2) (Figure 1B). Their ortholog AtCBL8 was shown to be mainly distributed in the cytoplasm and nucleus, and it also has a PM association (Batistic et al., 2010), indicating that CBL8 might have a unique mechanism for PM localization.

Type II includes 7 NtCBL members (Figure 1A, Table 1) that are the orthologs of AtCBL2/3/6/7. NtCBL2/3 contain the consensus tonoplast targeting sequence (TTS, MSQCXDGXKHXCXSXXXC_F) (Figure 1C) that is also present in AtCBL2 and AtCBL3 (Tang et al., 2012). In *Arabidopsis*, AtCBL2, AtCBL3, and AtCBL6 have been reported to localize to the tonoplast (Batistic et al., 2010). The *S*-acylation of the C residues at position 4 and position 18 is necessary for effective tonoplast targeting, while the substitution of C residue at position 12 of AtCBL2 resulted in the presence of a fraction of this protein in the cytoplasm and nucleus (Batistic et al., 2012). NtCBL2/3 have C residues at positions 4 and 18 but not at position 12, indicating they may be primarily but not exclusively localized to the tonoplast. AtCBL7 diverges from other type II-AtCBLs in the phylogenetic tree because it contains a deletion in

its N-terminus (Figure 1A-B) (Kleist et al., 2014). The key C residue at position 4 is not present in AtCBL7, which might be the reason for its diffused nuclear and cytosolic localization (Batistic et al., 2010). NtCBL7A/7B also have deletions in their N-termini, but they still have both key conserved C residues for tonoplast localization, therefore they might still be tonoplast-localized. NtCBL6A also has a short deletion in its N-terminus between the C residues at positions 4 and 18 (Figure 1C). Whether this deletion affects NtCBL6A localization to the tonoplast remains to be clarified.

NtCBL10A/10B belong to type III (Figure 1A, Table 1). Both NtCBL10A and NtCBL10B are predicted to contain a transmembrane (TM) helix for membrane association, similar to AtCBL10 (Figure 1D). AtCBL10 was found to be localized to the PM, as well as endosomal and tonoplast compartments (Kim et al., 2007; Quan et al., 2007; Batistic et al., 2010). The tonoplast association of AtCBL10 also requires S-acylation of the C residue at position 38 (Figure 1D) and appears to be essential in response to salt stress (Chai et al., 2020). The substitution of this C residue to Ser (S) in AtCBL10 leads to cytoplasmic and nuclear localization and dysfunction under salt stress (Chai et al., 2020). Both NtCBL10A and NtCBL10B contain the key C residue (at position 38 in AtCBL10). In addition, NsYL10, an *N. sylvestris* CBL protein with the same amino acid sequence as NtCBL10A and three amino acids difference from NtCBL10B, was verified to associate with the PM (Dong et al., 2015). Therefore, it is highly possible that NtCBL10A and NtCBL10B are also localized to the PM, as well as to the endosomes and tonoplast.

Prediction of tertiary structure and Ca^{2+} -binding affinity of NtCBLs

The presence of EF-hands in the CBL proteins confers the ability to bind Ca^{2+} and respond to Ca^{2+} -mediated environmental cues. Whether they bind Ca^{2+} also depends on the spatial location of the EF-hands in the folded CBL protein. However, little is known about the tertiary structure of CBL proteins. Until now, only the crystallographic structures of AtCBL2 and its binary complex with the C-terminus of AtCIPK14, as well as AtCBL4 and its binary complex with the C-terminus of

AtCIPK24 have been determined (Nagae et al., 2003; Sanchez-Barrena et al., 2005; Sanchez-Barrena et al., 2007; Akaboshi et al., 2008). We predicted the tertiary structures of NtCBLs using the SWISS-MODEL (Waterhouse et al., 2018) to further assess the diversity of the EF-hand functionality in the NtCBL family. The tertiary structures of several NtCBLs fit together, which are NtCBL4/5/8A-2/8B-2, NtCBL2/3/6A, NtCBL1/7/9/10, and NtCBL8A-1/8B-1. The backbones of their EF-hands are displayed in Figure 2.

Figure 2. The tertiary structure of EF-hands of NtCBLs. The tertiary structures were built based on the whole protein backbones, and only the backbones of EF-hands were displayed.

EF-hands are composed of two α -helices and an intervening loop, and several key amino acids in the intervening loop are important for Ca^{2+} -binding affinity (Batistic and Kudla, 2004). In *Arabidopsis* CBLs, the loop regions of EF2/3/4 consist of 12 amino acids while that of EF1 is extended to 14 amino acids. Positions 1, 5, 7, 9, 11, and 14 of the EF1 loop as well as positions 1, 3, 5, 7, 9, and 12 of EF2/3/4 loop are coordinates X, Y, Z, -Y, -X, -Z for Ca^{2+} -binding (Nagae et al., 2003; Batistic et al., 2009). Among them, coordinate -X of the EF-hand is a hydrophilic amino acid that binds Ca^{2+} via a water molecule, while other coordinates bind Ca^{2+} via side-chain donor oxygen or main-chain carbonyl oxygen (Nagae et al., 2003; Batistic et al., 2009; Sánchez-Barrena et al., 2013). The positions of the key amino acids for Ca^{2+} -binding in the loop region of EF-hands in NtCBLs (14 amino acids for the EF1 loop and 12 amino acids for the loops of EF2, EF3, and EF4) are predicted and listed in Table 2. The conserved amino acid sequences of EF-hands are presented in Figure

3. Based on the analysis, EF1/2/4 of NtCBLs were predicted to have two types of Ca^{2+} -oxygen (Ca-O) binding ways (marked with red or green squares in Figure 3), while EF3 of NtCBLs has one. The representative Ca-O binding structures are displayed correspondingly on the right of the panels (Figure 3).

Table 2 The positions of Ca^{2+} -binding amino acids in the loop region of EF-hands and their Ca^{2+} -binding ways

Name	Ca^{2+} -binding amino acids of EF1	amino acids of EF2	Ca^{2+} -binding amino acids of EF3	Ca^{2+} -binding amino acids of EF4

Numbers in the table indicate the positions of Ca^{2+} -binding amino acids in the loop region of EF1, 2, 3, and 4. Twice the same number (12, 12) in one EF-hand means the amino acid at position 12 in the loop region binds Ca^{2+} with two oxygens. “—” means that no Ca^{2+} -binding amino acid was detected. Red or green squares displayed on the right of the numbers represent different Ca^{2+} -oxygen binding ways displayed in Figure 3. The amino acids for Ca^{2+} -binding were predicted by the SWISS-MODEL online tool (<https://swissmodel.expasy.org/>).

Figure 3. The Ca²⁺-binding sites in the loop region of EF-hands. (A-D) The amino acid sequence alignments and tertiary structures of the loop region with predicted Ca²⁺-binding sites of EF-hands EF1 (A), EF2 (B), EF3 (C), and EF4 (D). Numbers above the aligned sequences indicate the position of predicted Ca²⁺-binding sites in EF-hand loops. Squares at the right side of the aligned sequences indicate different Ca²⁺-oxygen binding ways (red or green), with an example of each Ca²⁺-binding structure for this EF-hand displayed on the right of the panels. The tertiary structures were predicted by SWISS-MODEL (<https://swissmodel.expasy.org/>) (Waterhouse et al., 2018) and visualized via Swiss-Pdb Viewer (Guex et al., 1997).

The amino acid sequence of the EF-hand is not the only factor to influence Ca^{2+} -binding ability. For example, the EF3 of NtCBL2 is predicted to bind Ca^{2+} through positions 1, 6, 7, and 12. However, the EF3 of NtCBL7, with the same amino acid sequence as that of NtCBL2, is predicted to lack Ca^{2+} -binding ability (Figure 3C). To better understand the requirements for Ca^{2+} -binding affinity, the tertiary structures of NtCBL EF3 hands were examined in more detail. NtCBLs with similar EF3 tertiary structures (Figure 2) and the same Ca^{2+} -binding amino acids (Figure 3) are represented by one of them for analysis. To be specific, NtCBL2A is selected for NtCBL2/3, NtCBL1A-1 for NtCBL1/7/10, NtCBL4A-1 for NtCBL4/8A-2/8B-2, NtCBL5A for NtCBL5, and NtCBL8A-1 for NtCBL8A-1/8B-1. It was predicted that the EF3 of NtCBL2A binds Ca^{2+} with the oxygen atoms of amino acids D130, G135, F136, and E141 (providing 2 oxygen atoms) (Figure 4A). But the EF3 hand of NtCBL6A might possess an impaired Ca^{2+} -binding ability, because it has a G129 spatially positioned in the place of E141 (Figure 4B). G122 and F123 in NtCBL1A-1 spatially replace G135 and F136 of NtCBL2A (Figure 4C), which induce the spatial change of donor oxygen, thereby might strongly affect the Ca^{2+} -binding abilities. Similar changes were also predicted in the EF3 of NtCBL4/5/8/9 (Figure 4D-F). In summary, the spatial position of donor oxygens in the loop region of EF-hands might also be important for Ca^{2+} -binding.

Figure 4. Predicted Ca^{2+} -binding sites in loop regions of EF3 of NtCBLs. The tertiary structures of EF3 were predicted by SWISS-MODEL (<https://swissmodel.expasy.org/>) (Waterhouse et al., 2018), and the potential Ca^{2+} -binding sites were visualized via Swiss-Pdb Viewer (Guex et al., 1997).

In addition, the interaction with CIPKs may also affect the Ca^{2+} -binding affinity of CBL by modifying the tertiary structure of an EF-hand (Sánchez-Barrena et al., 2013). The analysis of the crystal structure showed that AtCBL2 in free form (without binding AtCIPK) binds two Ca^{2+} ions while the AtCBL2-AtCIPK14 C-terminus complex binds four; EF2 and EF3 of AtCBL2 in free form do not bind Ca^{2+} but they are occupied by Ca^{2+} in the AtCBL2-AtCIPK14 complex (Nagae et al., 2003; Akaboshi et al., 2008). Another example is about AtCBL4. Free AtCBL4 binds four Ca^{2+} ions while the AtCBL4-AtCIPK24 C-terminus complex only binds two; EF2 and EF3 of AtCBL4 in free form bind Ca^{2+} but lose the Ca^{2+} -binding ability when AtCBL4 is bound to AtCIPK24 (Sanchez-Barrena et al., 2005; Sanchez-Barrena et al., 2007). Those findings indicate that the interaction of CBLs with CIPKs might in turn affect the Ca^{2+} -binding properties of CBLs. Hereby, it is important to note that the Ca^{2+} -binding ability of NtCBLs in this study is predicted for the free form, and that this binding ability may change when the CBL is part of a protein-protein complex. The EF-hands without Ca^{2+} -binding ability in free form may regain Ca^{2+} -binding ability when the tertiary structures of NtCBLs are modified by interacting proteins.

Analysis of gene structure and splicing variants of NtCBLs

The presence of differentially spliced isoforms of *CBL* and *CIPK* genes introduces additional complexity to the CBL-CIPK signaling system. A previous study showed that the splicing variants of *AtCIPK3* were differentially regulated, and their encoded proteins displayed distinct interaction preferences. Specifically, *AtCIPK3.1* and *AtCIPK3.4* variants were found to be relatively more induced by ABA and drought treatment, and *AtCIPK3.1* and *AtCIPK3.2* showed an interaction preference for ABSCISIC ACID-RESPONSIVE 1 (ABR1) (Sanyal et al., 2017). Nevertheless, information on alternative splicing of CBL and CIPK families is still limited, and the

biological significance of the resulting diversity in protein isoforms is not yet fully understood (Kolukisaoglu et al., 2004).

In this study, the gene structures of *NtCBLs* were predicted with the gene structure annotation pipeline in the NCBI database (<https://www.ncbi.nlm.nih.gov/>). The predicted introns, exons, and splicing variants are depicted in Figure 5. Eighteen *NtCBLs* were predicted to have splicing variants, except *NtCBL3A*, *NtCBL6A*, *NtCBL7A*, *NtCBL7B*, *NtCBL10A*, and *NtCBL10B*. Remarkably, only *NtCBL2/4A-1/4A-2/5/9B* (5 of the 18 *NtCBLs*) encode splicing variants that are translated into proteins of different lengths. Most of the *NtCBL* genes were predicted to have introns in their 5'-untranslated region (UTR): a single intron in most type I members (*NtCBL1/4B/8A-1/8B-1/8B-2/9*), and two introns in most type II members (*NtCBL2/3/7*). In addition, homoeologous genes from parental genomes have 5'-UTRs that differ in length and intron presence.

Alternative splicing in 5'-UTRs can regulate translation efficiency by producing mRNA variants that differ in terms of upstream open reading frames (uORFs) or riboswitches (the metabolite-sensing gene-control elements that are typically located in the noncoding portion of mRNAs) (Roy and Arnim, 2013; Srivastava et al., 2018). Whether the alternative splicing in 5'-UTRs of *NtCBLs* affects gene expression and translation efficiency at the post-transcriptional level remains to be established. This is worth exploring because posttranscriptional regulation may be useful in the activation of stress tolerance mechanisms and developmental transitions (Srivastava et al., 2018).

Figure 5. Gene structure of *NtCBL* genes. The information on exon-intron organizations was obtained from NCBI (<https://www.ncbi.nlm.nih.gov/>) and visualized with the Gene Structure Display Server (GSDS, <http://gsds.cbi.pku.edu.cn/>) of *NtCBL* family genes. The coding sequences (CDSs) and genomic sequences were obtained from NCBI.

Most identified *NtCBL* genes have seven introns in their coding regions (Figure 5),

while the gene structure of *NtCBL6A* differs from the others. *NtCBL6A* was predicted to be intronless, which was confirmed by PCR using genomic DNA as a template. This lack of introns is highly unusual for plant *CBL* genes. No intronless *CBL* member has been identified in *Arabidopsis* or rice genomes (Kolukisaoglu et al., 2004). These findings suggest that *NtCBL6A* may have lost its introns after the evolutionary divergence of *N. tabacum* from *Arabidopsis* and rice (Kolukisaoglu et al., 2004). Further analysis showed that *NtCBL6A* does not have an ortholog in the paternal progenitor *N. tomentosiformis* (Table 1), nor does it have close homologs in *N. attenuata* and other *Solanaceae* crops (*Solanum tuberosum*, *S. lycopersicum*, *S. pennellii*, and *Capsicum annuum*) (Figure S2). These results indicate that *NtCBL6A* may be a unique gene in *solanaceae* plants. However, more information is required to determine whether *NtCBL6A* has any function in tobacco.

Analysis of *cis*-acting elements in the promoter regions of *NtCBLs*

CBLs play important roles in plant development and stress responses, and their expression is regulated by plant hormones and stress-related transcription factors (Albrecht et al., 2003; Guo et al., 2010). Therefore, the promoter sequences of *NtCBLs* were analyzed, and the predicted hormone- and stress-responsive *cis*-acting elements in the 3 kb upstream sequences of *NtCBL* coding sequences were displayed in Figure 6. Many hormone-responsive and stress-responsive elements were found in the promoter regions of *NtCBLs*. Among these, ABRE, STRE, and MYC elements are widespread and abundant in most promoters of *NtCBLs* (Figure 6A). The promoters of *NtCBL1A-2/1A-3* and *NtCBL4A-1/4B* are rich in ABRE elements, the *NtCBL8B-1* promoter is rich in TGACG-motifs, and the *NtCBL10B* promoter has multiple ERE elements (Figure 6A), indicating the expression of these genes may be greatly regulated by ABA, MeJA, and ethylene, respectively. The promoters of *NtCBL8B-2* and *NtCBL4B* are enriched in Myb and W-box elements, respectively (Figure 6A), suggesting their expression level might be regulated by Myb and WRKY transcription factors.

To explore the *NtCBLs* with potentially similar expression profiles, the *NtCBLs* were clustered based on the presence of the *cis*-acting elements in their promoters (Figure 6B). It was found that some genes are clustered together (e.g. *NtCBL7A/8A-1*, *NtCBL5/7B/8A-2*, *NtCBL2A/3A/6A/9A*, *NtCBL1A-2/4A-2*, *NtCBL4B/4A-1*, *NtCBL1A-3/3B/8B-2*, and *NtCBL1A-1/1B/2B/9B/10*) (Figure 6B), suggesting these genes might be responsive to the same hormones and stress factors. For instance, there are many STREs (stress response elements) present in the promoter region of the clustered *NtCBL5/7B/8A-2*, and ABRE (*cis*-acting element involved in the abscisic acid responsiveness) in the promoter region of the clustered *NtCBL4B/4A-1*. Interestingly, most homoeologous *NtCBL* gene promoters from the two ancestral genomes do not have a highly similar *cis*-acting element presence (except *NtCBL10A/10B* and *NtCBL5A/5B*) (Figure 6B), suggesting that they may have differential expression responses to hormones and stress. This is consistent with the previous reports that the expression of genes from parental genomes needs to be orchestrated for their harmonious co-existence in allopolyploidy (Feldman and Levy, 2009; Akhunova et al., 2010).

Figure 6. Analysis of *cis*-acting elements in the promoters of *NtCBL* genes. (A) Heatmap of *cis*-acting elements in *NtCBL* promoter regions ordered based on the phylogenetic relationship of the genes. (B) Heatmap of *cis*-acting elements in *NtCBL* promoter regions ordered based on similarity of *cis*-acting element presence. The intensity of the color represents the number of *cis*-acting elements in the *NtCBL* gene promoters. ABRE (*cis*-acting element involved in the abscisic acid responsiveness), AuxRR-core (the core of the auxin response region), ERE (ethylene-responsive *cis*-acting), TCA-element (*cis*-acting

element involved in salicylic acid responsiveness), TGACG-motif (*cis*-acting regulatory element involved in the methyl jasmonate (MeJA)-responsiveness), STRE (stress response element), ARE (anaerobic induction element), LTR (low-temperature-responsive element), TC-rich repeats (involved in defense and stress responsiveness), MBS (MYB binding site involved in drought-inducibility) (Sugimoto et al., 2000), Wun-motif (wound-responsive element), Myb (MYB-binding site) (Sugimoto et al., 2000), MYC (MYC recognition element), W-box (WRKY binding site) (Liu et al., 2016), WRE3 (wound-responsive element) (Yu et al., 2021), DRE1 (dehydration-responsive element).

Expression profiles of *NtCBL* genes in different tobacco tissues at the young stage and adult stage

The ancestral function of *CBL* genes is the regulation of ion homeostasis, and this has diversified during evolution (Kleist et al., 2014; Edel and Kudla, 2015). Functional diversification of *CBL* genes is reflected not only in the structural differences of proteins but also in the expression differences of genes. For example, *Arabidopsis* AtCBL4 and AtCBL10 mediate two independent salt tolerance pathways in different tissues because of their tissue-predominant expression patterns (Yang et al., 2019). *AtCBL4* is expressed and exerts its function in roots while *AtCBL10* is mainly expressed and functional in shoot green tissues (Kim et al., 2007; Quan et al., 2007). *AtCBL2* and *AtCBL3* on the other hand have largely overlapping expression patterns (Eckert et al., 2014) and their encoded proteins are structurally similar, so they were shown to be functionally redundant in both plant development and stress response (Tang et al., 2012; Steinhorst et al., 2015; Tang et al., 2015; Song et al., 2018; Tang et al., 2020b; Ju et al., 2022).

To get insight into the potential functions of *NtCBL* genes, we monitored their expression profiles in different tissues (leaf blade, main vein, stem, and root) of young tobacco plants (35 days after germination) by RT-qPCR (Figure 7A-D, primers are listed in Table S1). In young plants, *NtCBL2/3/7/10/1A-3/4A-1* had higher expression levels (Figure 7A), *NtCBL8/9/4A-2/4B* had medium expression levels (Figure 7B), and *NtCBL1A-1/1A-2/1B/4A-2/4B/5/8A-1/8A-2/8B-2* had very low

expression levels (Figure 7C). The expression of *NtCBL6A* was not detected in any sampled tissues in this study, but *NtCBL6A* may be expressed in some other tissues or at some specific developmental stages. In addition, several *NtCBL* genes exhibited a shoot- or root-predominant expression pattern: *NtCBL10* was predominantly expressed in shoot tissues while *NtCBL4A-1/8B-1/9* were mainly expressed in roots. The tissue-predominant expression patterns of *NtCBL4A-1* and *NtCBL10* are similar to that of their orthologs in *Arabidopsis* (Kim et al., 2007; Quan et al., 2007; Eckert et al., 2014), which suggests that they might have similar roles.

The expression profiles of 24 *NtCBL* genes in different tissues (leaf, root) of adult plants were also analyzed using published RNA-seq data (Figure S3). Results showed that the expression profile of most *NtCBL*s at the adult stage is similar to that at the young plant stage, but *NtCBL4B* appeared to have a much higher expression level in both leaf and root at the adult stage (Figure S3), indicating that *NtCBL4B* may function at later developmental stages of the tobacco plant.

The interaction between homoeologous genomes in allopolyploidy orchestrates gene expression genome-wide, contributing to growth vigor and the broader phenotypic diversity of allopolyploid species (Feldman and Levy, 2009; Akhunova et al., 2010). We found that *NtCBL1A-3/4A-1/7A/9A/10A* from the maternal genome (*N. sylvestris*) and *NtCBL3B/5B/8B-1* from the paternal genome (*N. tomentosiformis*) are the dominant homoeologs in young plants (Figure 7). However, *NtCBL4B* and *NtCBL9B* are dominant in adult leaves and roots, respectively (Figure S3). These results indicate that the homoeologs of some *NtCBL* genes are differentially expressed at the mRNA level (Hovav et al., 2007).

Figure 7. Expression profiles of *NtCBL* genes in different tissues of tobacco at the young stage. (A–C) Relative expression analysis of *NtCBL* genes in leaf blade (L), main vein (V), stem (S), and root (R) of young tobacco plants determined by RT-qPCR, which were grouped in three panels according to their expression levels (highest in panel A, lowest in panel C). The expression of these genes is relative to that of the reference gene *NtL25* (Schmidt and Delaney, 2010). The tobacco plants used for sampling were cultivated in a hydroponic system. Different tissues (leaf blade: leaf with main veins removed; main vein; stem; root) were sampled at 35 days after germination. Error bars indicate \pm SD (n=6 for gene expression detection), and different letters above bars (a, b, and c) indicate significant statistical differences of a *NtCBL* gene expression in different tissues (one-way ANOVA with the LSD test, p<0.05).

Expression profiles of *NtCBL* genes in leaves from young tobacco plants under salt and drought stress

CBL proteins are reported to be involved in multiple stress responses (Tang et al., 2020a), and many hormone- and stress-responsive *cis*-acting elements were

identified in the promoter regions of *NtCBL* genes. Therefore, we analyzed the expression of *NtCBL* genes in young tobacco leaves under salt stress and drought stress using RT-qPCR (Figure S4). Under salt stress, the expression levels of *NtCBL3A/3B/7A/7B/8B-1/10A/10B* in leaves were increased, and the expression levels of *NtCBL1A-2/2A/4A-1/7A/7B/8B-2* in roots were reduced (Figure 8A). Under drought stress, the expression levels of *NtCBL2A/2B/3A/3B/4B/7A/7B* were reduced, while the expression of *NtCBL10B* was upregulated (Figure 8B).

Arabidopsis AtCBL10 and *N. sylvestris NsylCBL10* (GeneBank accession number: KF667488.1), the orthologs of *NtCBL10*, were reported to be positive regulators of salt tolerance (Kim et al., 2007; Dong et al., 2015). The loss-of-function mutant of *AtCBL10* exhibited growth defects under saline conditions (Kim et al., 2007), and overexpression of *NsylCBL10* improved the salt tolerance of transgenic *Arabidopsis* (Dong et al., 2015). In this study, the expression levels of *NtCBL10A* and *NtCBL10B* are upregulated under salt stress. These results strongly suggest that *NtCBL10A* and *NtCBL10B* may play a role in the salt tolerance of tobacco as well. Under drought stress, the loss-of-function mutant of *AtCBL10* had increased drought tolerance in *Arabidopsis* (Kang and Nam, 2016), which is inconsistent with the up-regulation of *NtCBL10B* expression reported here. Further functional analysis is needed to understand the role of *NtCBL10B* in response to drought stress.

AtCBL4 (also known as SOS3), interacts with *AtCIPK24* (also known as SOS2) to activate the PM-localized Na^+/H^+ exchanger *AtSOS1*, transporting Na^+ out of the root cell and enhancing the salt tolerance of *Arabidopsis* (Qiu et al., 2002; Shi et al., 2002; Nunez-Ramirez et al., 2012). *CBL4* has been reported to contribute to salt stress tolerance in many other plant species including *Oryza sativa* (Martinez-Atienza et al., 2007), *Setaria italica* (Zhang et al., 2017), *Brassica napus* (Liu et al., 2015), *Solanum lycopersicum* (Cho et al., 2021), and *Tamarix hispida* (Liu et al., 2020). In our study, the expression of *NtCBL4A-1* in roots was inhibited by salt stress, which does not seem consistent with the conserved role of *CBL4* in other plant species. This may point to a different function for *NtCBL4A-1* under salt stress compared to *AtCBL4*.

Figure 8. Expression profiles of *NtCBL* genes in tobacco leaves under salt stress and drought stress were determined by RT-qPCR. (A and B) Relative expression analysis of significantly regulated *NtCBL* genes in leaf blades and roots under salt stress (1 day after the start of 100 mM NaCl treatment), respectively. **(C)** Relative expression analysis of significantly regulated *NtCBL* genes in leaf blades under drought stress (5 days after stopping water). The expression of these genes is relative to that of the reference gene *NtL25* (Schmidt et al., 2010). Error bars indicate \pm SD (n=3), every biological replicate is a mixed pool of 3 plants. Asterisks indicate statistically significant differences (Student's *t* test, **p*<0.05 and ***p*<0.01).

Overexpression of *NtCBL4A-1* leads to Na⁺-induced salt sensitivity of transgenic tobacco plants

To better understand the role of *NtCBL4A-1* in the salt stress response of tobacco, two independent *NtCBL4A-1*-overexpressing (*NtCBL4A-1*-OE) lines (OE-2, OE-9) (Figure 9A, B) were selected and evaluated for salt tolerance. Under control conditions, wild-type (WT) and two *NtCBL4A-1*-OE lines exhibited similar growth vigor (Figure 9C-F). Under 100 mM NaCl treatment, however, *NtCBL4A-1*-OE lines exhibited salt-sensitive phenotypes with severe necrotic lesions on their leaves (Figure 9C). In addition, the plant height and shoot fresh/dry weight of *NtCBL4A-1*-OE lines were slightly lower than that of WT plants under salt stress (Figure 9D-F). Ion content analysis (Na⁺, K⁺, and Ca²⁺ in the 5th leaf blades) revealed that K⁺ and Ca²⁺ contents of all three lines were significantly reduced under salt stress, but there is no significant ion content difference between WT and *NtCBL4A-1*-OE lines (Figure 9H, I). The Na⁺ content of *NtCBL4A-1*-OE lines is only slightly higher than that of WT (Figure 9G).

Figure 9. The detection of *NtCBL4A-1* expression and above-ground phenotype of wild-type (WT) and *NtCBL4A-1*-overexpressing (OE) lines (OE-2 and OE-9) under control conditions and salt stress (100 mM NaCl). Scale bars=10 cm. **(A and B)** Relative expression analysis of endogenous and exogenous *NtCBL4A-1* determined by RT-qPCR in leaves. The expression of *NtCBL4A-1* is relative to the reference gene *NtL25*. The reverse primer pCHF3-Allcheck-2 (Shi et al., 2021) used for amplifying exogenous *NtCBL4A-1* was designed according to the sequence of the overexpression vector pCHF3. **(C)** The shoot phenotype of WT and *NtCBL4A-1*-OE lines at 9 DAT. **(D-F)** The plant height, shoot fresh weight, and shoot dry weight of WT and *NtCBL4A-1*-OE lines at 9 DAT. Error bars indicate \pm SD ($n=3$ for gene expression detection, $n=6$ for plant height and shoot fresh/dry weight determination). **(G-I)** The Na⁺, K⁺, and Ca²⁺ contents of the 5th leaves of WT and *NtCBL4A-1*-OE lines. Error bars indicate \pm SD ($n=3$), every biological replicate is a mixed pool of 3 plants. Different letters above bars (a, b, and c) indicate significant statistical difference based on one-way ANOVA with LSD test ($P<0.05$).

Salt stress imposes both osmotic stress and ionic stress on plants (Munns, 2005). To identify which stress component (osmotic or ionic) is responsible for the necrotic phenotype of *NtCBL4A-1*-OE lines under 100 mM NaCl conditions, a 15% PEG6000-mimic osmotic treatment (osmotic pressure is similar to 100 mM NaCl) and ionic treatments (100 mM NaCl, 100 mM NaNO₃, 100 mM KNO₃, and 100 mM KCl) were conducted. Compared with WT, *NtCBL4A-1*-OE lines exhibited necrotic lesions and growth penalties only under treatments of 100 mM NaCl and NaNO₃, but not under osmotic stress or 100 mM KNO₃ and KCl (Figure 10). These results indicate that the increased salt sensitivity of *NtCBL4A-1*-OE lines is Na⁺ dependent.

Figure 10. Ion and osmotic stress evaluation on wild-type (WT) and *NtCBL4A-1*-overexpressing lines (OE-2 and OE-9) at 9 days after the start of treatment. Scale bars=10 cm. **(A-F)** The phenotype of WT and *NtCBL4A-1*-OE lines under control condition (1/2 Hoagland's nutrient solution), osmotic stress (1/2 Hoagland's nutrient solution added 15% PEG6000, ion stresses (1/2 Hoagland's nutrient solutions added 100mM NaCl, 100mM NaNO₃, 100mM KCl, and 100mM KNO₃, respectively). Scale bars=10cm. **(G-J)** The plant height, shoot fresh weight, 5th leaf width, and 5th leaf length of WT and *NtCBL4A-1*-OE lines at 9 DAT Error bars indicate \pm SD (n=6). Asterisks indicate statistically significant differences (Student's *t* test, **p*<0.05 and ***p*<0.01).

CBL4 and CBL5 share high sequence similarity and they belong to the type I CBLs (Figure 1A). In *Arabidopsis* and *S. italica*, both *CBL4* and *CBL5* were reported to be responsible for the salt tolerance of plants (Zhu, 2000; Cheong et al., 2010; Zhang et al., 2017; Yan et al., 2022). However, our results showed that the overexpression of *NtCBL4A-1* and *NtCBL5A* enhanced the salt sensitivity of transgenic tobacco plants based on this study and our previous report (Mao et al., 2021). Both *NtCBL4A-1*- and *NtCBL5A*-OE lines exhibited necrotic lesions on leaves under salt stress. In addition, the Na⁺ content increases in both *NtCBL4A-1*- and *NtCBL5A*-OE lines were only slightly higher than that in WT under salt stress, indicating that the overexpressing lines exhibit higher Na⁺ sensitivity than WT. Therefore, we speculate that the Na⁺-sensitive mechanisms underlying the salt sensitivity of *NtCBL4A-1*-OE lines might be similar to that of *NtCBL5A*-OE lines, which is still unclear until now. A possible hypothesis is that the ectopic (over)expression of *NtCBL5A* might compete with other components of the CBL-CIPK network for Na⁺ vacuolar compartmentalization, leading to abnormal Na⁺ distribution (Mao et al., 2021). Considering many photosynthetic machinery-related genes were strongly inhibited and plant defense-related genes were induced under salt stress, the Na⁺ sensitivity of *NtCBL5A*-OE lines may also be related to defective photosystems or induced plant immune response. The next step would be to identify the common interacting proteins of *NtCBL4A-1* and *NtCBL5A*, some of which could be key components in the salt tolerance system of tobacco (Mao et al., 2021). The elucidation of these

questions will broaden our knowledge of the CBL-CIPK network and the salt stress response of plants.

CONCLUSIONS

In this study, a detailed analysis of *NtCBL* family genes was conducted by bioinformatic analysis and expression profile analysis. The homoeologous genes from the two parental genomes were predicted to encode proteins with key amino acids and similar tertiary structures for subcellular localization and Ca^{2+} -binding ability. Some *NtCBL* homoeologs from the two parental genomes are differentially regulated at the transcriptional level. The bioinformatics-supported information will serve as a basis for further research, including the characterization of family genes by using gene overexpressing or knock-out plants, elucidating their roles in stress response and growth trade-off, and accessing allelic variation to improve crop performance through breeding. In addition, the genetic experiment of *NtCBL4A-1* indicates the potential role of *CBL* genes in salt stress response. In summary, this study lays a good foundation for the functional characterization of *NtCBL* genes, and knowledge about these genes in tobacco will therefore likely support breeding efforts for improved *Solanaceae* crops under suboptimal conditions.

FUNDING INFORMATION

This work was supported by the National Natural Science Foundation of China (32170387); International Foundation of Tobacco Research Institute of CAAS (IFT202102); Key Funding of CNTC (No. 110202101035(JY-12)); Key Funding of YNTI (No. 2020JC03, 2022JY03); and International Exchange Scholarship of the GSCAAS.

CREDIT AUTHORSHIP CONTRIBUTION STATEMENT

J.M. designed the research plan, carried out the experiments, and analyzed the data; J.M., C.G.V.L., and Q.W. completed the writing; H.L., Q.W., and C.G.V.L. co-supervised the writing; Y.G., K.H., H.X., and W.Z. provided ideas and joined discussion; R.G.F.V. and Y.B. helped with manuscript revision. H.L. and Q.W. agree

to serve as the authors responsible for contact and ensure communication. All authors contributed to the article and approved the submitted version.

DECLARATION OF INTERESTS

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

DATA AVAILABILITY

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found in the article/supplementary material.

ACKNOWLEDGMENTS

We would like to acknowledge the support of the PhD Education Programs between The GSCAAS and WUR. We would like to thank Jiangtao Chao from Tobacco Research Institute, Chinese Academy of Agricultural Sciences (CAAS) for helping to analyze the RNAseq data.

Supplementary Material

Figure S1. The domain analysis of NtCBLs. Amino acid sequence alignment of NtCBLs. The amino acid sequences alignment of NtCBLs were performed using Clustal Omega (<https://www.ebi.ac.uk/Tools/msa/clustalo/>) and displayed by GeneDoc (Nicholas, 1997). The domains of NtCBLs were predicted by the SMART online tool (<http://smart.embl-heidelberg.de/>).

Figure S2. Phylogenetic analysis of the CBL families in *N. tabacum*, *A. thaliana*, *S. tuberosum*, *S. lycopersicum*, *S. pennellii*, and *C. annuum*. The amino acid sequences were downloaded from NCBI (<https://www.ncbi.nlm.nih.gov/>). The phylogenetic tree was constructed by MEGA6 using the Neighbor-Joining method.

Figure S3. Expression profiles of *NtCBL* genes in different tissues of tobacco plants at the adult stage. Gene expression level of *NtCBL* genes in leaves **(A)** (SRA accession ID: SRX2655430, SRX2655478, SRX2655480, SRX2655632, SRX2655633, SRX2655634) and roots **(B)** (SRA accession ID: SRX4407884, SRX4407877, SRX4407878) of tobacco at the adult stage that determined by published RNA-seq data (Li et al., 2017; Qin et al., 2020). The six biological replicates (every two replicates for upper, middle, and lower leaves) of leaves are sampled at 15 days after topping (75 days after transplanting) (Li et al., 2017), while the three biological replicates of roots are sampled at 0 h after topping (56 days after transplanting) (Qin et al., 2020).

Figure S4. Expression profiles of *NtCBL* genes in tobacco leaves under salt stress and drought stress were determined by RT-qPCR. (A and B) Heatmap pictures display the expression profiles of *NtCBL*s in leaf blades and roots under salt stress (1 day after the start of 100 mM NaCl treatment), respectively. **(C)** Heatmap pictures display the expression profiles of *NtCBL*s in leaf blades under drought stress (5 days after stopping water). The genes were ordered based on the similar expression response to stresses. The expression of these genes under salt and drought stress is relative to that of the reference gene *NtL25* (Schmidt et al., 2010).

Table S1 | Primers used for RT-qPCR

Primer name	Sequence (5' to 3')	Description
NtCBL1A-1qF	GTTCTTCCTCGTTTGT CGTCCT	Forward primer for <i>NtCBL1A-1</i> , this primer was designed based on the 5'-UTR sequence of <i>NtCBL1A-1</i>
NtCBL1A-1qR	ACAGCTCAAACAATG CCTCAAC	Reverse primer for <i>NtCBL1A-1</i>
NtCBL1A-2qF	CCCTTTTATTGCTGGT TACTAG	Forward primer for <i>NtCBL1A-2</i> , this primer was designed based on the 5'-UTR sequence of <i>NtCBL1A-2</i>
NtCBL1B-qF	CTGTTCAGTGGACGG TCT	Forward primer for <i>NtCBL1B</i> , this primer was designed based on the 5'-UTR sequence of <i>NtCBL1B</i>
NtCBL1-qR	GAACAGCTCAAACAAT GC	Common reverse primer for <i>NtCBL1A-2</i> and <i>NtCBL1B</i>
NtCBL1A-3qF	ATTGGGTGGGGAGGA TGCTA	Forward primer for <i>NtCBL1A-3</i> , this primer was designed based on the 3'-UTR sequence of <i>NtCBL1A-3</i>
NtCBL1A-3qR	ACAGCATGCGTATCG TTCCA	Reverse primer for <i>NtCBL1A-3</i> , this primer was designed based on the 3'-UTR sequence of <i>NtCBL1A-3</i>
NtCBL2A-qF	CAGATTCATCTTATTT AGTCGTTT	Forward primer for <i>NtCBL2A</i> , this primer was designed based on the 5'-UTR sequence of <i>NtCBL2A</i>
NtCBL2B-qF	CATATTAGCATCCGTC TCC	Forward primer for <i>NtCBL2B</i> , this primer was designed based on the 5'-UTR sequence of <i>NtCBL2B</i>
NtCBL2-qR	CTCCGGATCTTCAAAG C	Common reverse primer for <i>NtCBL2A</i> and <i>NtCBL2B</i>
NtCBL3-qF	GACCCCTTCAGTATCTT AAGGAC	Common forward primer for <i>NtCBL3A</i> and <i>NtCBL3B</i>
NtCBL3A-qR	AACTCAGAATAGATGA GCAAGAC	Reverse primer for <i>NtCBL3A</i> , this primer was designed based on the 3'-UTR sequence of <i>NtCBL3B</i>
NtCBL3B-qR	GAAC TCAAAAATATAT GAGCAAAA	Reverse primer for <i>NtCBL3B</i> , this primer was designed based on the 3'-UTR sequence of <i>NtCBL3B</i>
NtCBL4-qF	GCACTGCTGCATGAA TC	Common forward primer for <i>NtCBL4A-1</i> , <i>NtCBL4A-2</i> , and <i>NtCBL4B</i> , even though this primer has a SNP with the CDS sequence of <i>NtCBL4A-2</i>

Chapter 3

3

Primer name	Sequence (5' to 3')	Description
NtCBL4A-1qR	GCATCATCACTGTGG AATAT	Reverse primer for <i>NtCBL4A-1</i> , this primer was designed based on the 3'-UTR sequence of <i>NtCBL4A-1</i>
NtCBL4A-2qR	AACTCCTTTGCACTCC ATAG	Reverse primer for <i>NtCBL4A-2</i> , this primer was designed based on the 3'-UTR sequence of <i>NtCBL4A-2</i>
NtCBL4B-qR	CTAATGTCTTTTTTGA TTCTTGA	Reverse primer for <i>NtCBL4B</i> , this primer was designed based on the 3'-UTR sequence of <i>NtCBL4B</i>
NtCBL5A-UTR-31F	TTTGCTAATAAACCCA TCTTTG	For the identification of endogenous <i>NtCBL5A</i> , NtCBL5A-UTR-31F was designed based on the 5'-UTR sequence of <i>NtCBL5A</i> (Mao et al., 2021)
NtCBL5A-81R	TCCAAAGAAAAATGTG TCTGAG	
NtCBL5B-595F	TTGTGCTGAATACAGA AGCG	Forward primer for <i>NtCBL5B</i>
NtCBL5BUTR-82R	TTCCTTTGATATTCGT GCAG	Reverse primer for <i>NtCBL5B</i> , this primer was designed based on the 3'-UTR sequence of <i>NtCBL5B</i>
NtCBL6A-qF	ATGAGCAACAATGCA GGGAC	Forward primer for <i>NtCBL6A</i>
NtCBL6A-qR	CCCGTTGTGCTTTGTG ACG	Reverse primer for <i>NtCBL6A</i>
NtCBL7A-qF	AATCTCCGTTTACATA TATAGCTC	Forward primer for <i>NtCBL7A</i> , this primer was designed based on the 5'-UTR sequence of <i>NtCBL7A</i>
NtCBL7B-qF	GAATCTCCGTATACTC ATAAAACA	Forward primer for <i>NtCBL7B</i> , this primer was designed based on the 5'-UTR sequence of <i>NtCBL7B</i>
NtCBL7-qR	GCCTAAAATCAAGATC ACAAC	Common reverse primer for <i>NtCBL7A</i> and <i>NtCBL7B</i>
NtCBL8A-1qF	TCCGAGCTTTGTCCTG	Forward primer for <i>NtCBL8A-1</i>
NtCBL8A-1qR	AAACAGATTTTCCACT ACGAC	Reverse primer for <i>NtCBL8A-1</i> , this primer was designed based on the 3'-UTR sequence of <i>NtCBL8A-1</i>
NtCBL8A-2qF	GCCAAATTCTATCCTG CTACTGC	Forward primer for <i>NtCBL8A-2</i> , this primer was designed based on the 3'-UTR sequence of <i>NtCBL8A-2</i>

Primer name	Sequence (5' to 3')	Description
NtCBL8A-2qR	ACCAGAAATGAAGAA AAAGGGAAA	Reverse primer for <i>NtCBL8A-2</i> , this primer was designed based on the 3'-UTR sequence of <i>NtCBL8A-2</i>
NtCBL8B-1qF	TCCGAGCTTTGTCCTA	Forward primer for <i>NtCBL8B-1</i>
NtCBL8B-1qR	AGATGTTTCCGATACG CT	Reverse primer for <i>NtCBL8B-1</i> , this primer was designed based on the 3'-UTR sequence of <i>NtCBL8B-1</i>
NtCBL8B-2qF	TTGATCCAGAAGAGT GGAAGG	Forward primer for <i>NtCBL8B-2</i>
NtCBL8B-2qR	AGAATTTTGGCAGTTG GCACC	Reverse primer for <i>NtCBL8B-2</i> , this primer was designed based on the 3'-UTR sequence of <i>NtCBL8B-2</i>
NtCBL9-qF	CAAATCTGAATGGCG AAG	Common forward primer for <i>NtCBL9A</i> and <i>NtCBL9B</i>
NtCBL9A-qR	TTTTGAACTAGCATTT CCTATTA	Reverse primer for <i>NtCBL9A</i> , this primer was designed based on the 3'-UTR sequence of <i>NtCBL9A</i>
NtCBL9B-qR	CTAATTCTGAACTACA TTTTCTACTC	Reverse primer for <i>NtCBL9B</i> , this primer was designed based on the 3'-UTR sequence of <i>NtCBL9B</i>
NtCBL10A-qF	CTTTCTCTCTCTCTCT CTGAATT	Forward primer for <i>NtCBL10A</i> , this primer was designed based on the 5'-UTR sequence of <i>NtCBL10A</i>
NtCBL10B-qF	ACCACATAAAAAACACA CACCTTT	Forward primer for <i>NtCBL10B</i> , this primer was designed based on the 5'-UTR sequence of <i>NtCBL10B</i>
NtCBL10-qR	GCTATTATTGGGAAAA ATGC	Common reverse primer for <i>NtCBL10A</i> and <i>NtCBL10B</i>
NtCBL4A-1F	ATGGGCTGCTTTCACT CC	Used for the clone of <i>NtCBL4A-1</i> CDS
NtCBL4A-1R	TTAGACTTCCAAATCT TCAACC	
NtCBL4A-1F- Kpn I	GGGTACCATGGGCTG CTTCACTCC	Used for the construction of plasmid pCHF3-NtCBL4A-1
NtCBL4A-1R- Xba I	CTCTAGATTAGACTTC CAAATCTTCAACC	

Chapter 3

Primer name	Sequence (5' to 3')	Description
pCHF3-62F	GCACAATCCCACTATC	For the identification of NtCBL4A-1-OE transgenic tobacco with NtCBL4A-1R
	CTTCG	
NtCBL4A-1-qF	AGTTCTTTCAGATGAT	For the identification of exogenous <i>NtCBL4A-1</i> , pCHF3-Allcheck-2 (Shi et al., 2021) was designed based on the
	GTTGTCG	
pCHF3-	GATGATACGAACGAA	sequence of 3'-UTR of exogenous gene
Allcheck-2	AGCTCTGC	

For the gene with splicing variants, the primer pair was designed from the common sequence of splicing variants of a gene.

Chapter 4

Overexpression of *NtCBL5A* leads to necrotic lesions by enhancing Na^+ sensitivity of tobacco leaves under salt stress

ABSTRACT

Many tobacco (*Nicotiana tabacum*) cultivars are salt-tolerant and thus are potential model plants to study the mechanisms of salt stress tolerance. The CALCINEURIN B-LIKE PROTEIN (CBL) is a vital family of plant calcium sensor proteins that can transmit Ca^{2+} signals triggered by environmental stimuli including salt stress. Therefore, assessing the potential of *NtCBL* for genetic improvement of salt stress is valuable. In our studies on *NtCBL* members, constitutive overexpression of *NtCBL5A* was found to cause salt supersensitivity with necrotic lesions on leaves. *NtCBL5A*-overexpressing (OE) leaves tended to curl and accumulated high levels of reactive oxygen species (ROS) under salt stress. The supersensitivity of *NtCBL5A*-OE leaves was specifically induced by Na^+ , but not by Cl^- , osmotic stress, or drought stress. Ion content measurements indicated that *NtCBL5A*-OE leaves showed sensitivity to the Na^+ accumulation levels that wild-type leaves could tolerate. Furthermore, transcriptome profiling showed that many immune response-related genes are significantly upregulated and photosynthetic machinery-related genes are significantly downregulated in salt-stressed *NtCBL5A*-OE leaves. In addition, the expression of several cation homeostasis-related genes were also affected in salt-stressed *NtCBL5A*-OE leaves. In conclusion, the constitutive overexpression of *NtCBL5A* interferes with the normal salt stress response of tobacco plants and leads to Na^+ -dependent leaf necrosis by enhancing the sensitivity of transgenic leaves to Na^+ . This Na^+ sensitivity of *NtCBL5A*-OE leaves might result from the abnormal Na^+ compartmentalization, plant photosynthesis, and plant immune response triggered by the constitutive overexpression of *NtCBL5A*. Identifying genes and pathways involved in this unusual salt stress response can provide new insights into the salt stress response of tobacco plants.

INTRODUCTION

Soil salinity causes serious yield losses because of its widespread occurrence and severe effects on crop physiology and metabolism (Munns and Tester, 2008). The potential crop yield losses induced by moderate salinity (8~10 dS/m) are about 55%, 28%, and 15% in corn, wheat, and cotton, respectively (Satir and Berberoglu, 2016). It is estimated that about 30% of irrigated lands are salt-affected and thus commercially unproductive (Zaman and Heng, 2018). There are several strategies for the utilization of salt-affected lands, one of which is to breed or genetically engineer new varieties suitable for saline soils (Gong et al., 2020). Therefore, understanding the mechanisms underlying the plant salt stress response is of fundamental importance to mitigating the negative impact of soil degradation.

Salt stress can be divided into two phases, the first of which is the osmotic or water-deficit stress (Munns, 2005; Van Zelm et al., 2020). When exposed to salinity stress, plants experience an immediate osmotic effect around root cells that impairs water uptake and disturbs associated cell growth and metabolism, similar to the effects of drought stress. The second phase is a salt-specific ion toxicity effect (Munns, 2005; Van Zelm et al., 2020). At prolonged exposure to salinity, Na^+ and Cl^- are transported to leaf blades by the transpiration stream. When the ions accumulate to high levels, they become toxic and cause damage (Munns et al., 2008). The osmotic stress can be measured as a rapid inhibition of the rate of expansion of young leaves, while ion toxicity causes stress-induced senescence of older leaves due to either high leaf Na^+ concentrations or low tolerance of the accumulated Na^+ (Munns et al., 2008).

Plants respond to the two phases of salinity stress via different signaling pathways (Bartels and Sunkar, 2005). Ca^{2+} functions as a secondary messenger to couple a wide range of extracellular stimuli to intracellular responses (Snedden and Fromm, 1998; Snedden and Fromm, 2001). Osmotic and salt stresses induce rapid $[\text{Ca}^{2+}]_{\text{cyt}}$ transients in the cytosol that trigger downstream pathways, allowing plants to adapt to these environmental changes by regulating enzymatic activity, ion channel activity,

and gene expression (Knight and Knight, 2001; Snedden and Fromm, 2001). The transduction of Ca^{2+} signals depends on Ca^{2+} -sensor proteins (Trewavas and Malhó, 1998). To date, four major classes of Ca^{2+} sensor proteins have been characterized in plants: CALMODULIN (CaM), CALMODULIN-LIKE PROTEIN (CML), CALCIUM-DEPENDENT PROTEIN KINASE (CDPK), and CALCINEURIN B-LIKE PROTEIN (CBL) (Perochon et al., 2011).

As vital Ca^{2+} -sensors, CBLs mainly function by regulating the kinase activity of their partners CBL-INTERACTING PROTEIN KINASEs (CIPKs) in response to various abiotic stresses including salt stress (Luan, 2009). So far, several CBLs from various plant species have been reported to participate in the salt stress response by facilitating Na^+ exudation and vacuolar sequestration. In the root, *Arabidopsis thaliana* AtCBL4 interacts with AtCIPK24 to unlock its kinase activity, and the activated AtCIPK24 can phosphorylate and activate the plasma membrane-localized Na^+/H^+ antiporter SALT OVERLY SENSITIVE 1 (SOS1), leading to Na^+ extrusion from root cells (Qiu et al., 2002; Shi et al., 2002; Gong et al., 2020). This so-called SOS pathway was found to be conserved in many other plant species including rice (*Oryza sativa*), poplar (*Populus trichocarpa* and *Populus euphratica*), mustard (*Brassica juncea*), and apple (*Malus domestica*) (Martinez-Atienza et al., 2007; Tang et al., 2010; Chakraborty et al., 2012; Hu et al., 2012; Lv et al., 2014). In the shoot, AtCBL10 is capable of interacting with both AtCIPK24 and AtCIPK8 to phosphorylate SOS1, and thus enhancing Na^+ efflux from cells (Quan et al., 2007; Lin et al., 2009; Yin et al., 2019). Moreover, the AtCBL10-AtCIPK24 complex was suggested to activate the tonoplast-localized Na^+/H^+ EXCHANGER (AtNHX) to sequester Na^+ into vacuole for salt storage and detoxification of the cytosol (Qiu et al., 2004; Kim et al., 2007). Orthologs of AtCBL10 in other species including wild tobacco (*Nicotiana glauca*), tomato (*Solanum lycopersicum*), and poplar (*P. trichocarpa* and *P. euphratica*) were also reported to be involved in the Na^+ tissue tolerance mechanism (Li et al., 2012a; Tang et al., 2014; Dong et al., 2015; Egea et al., 2018). There are other CBLs that may participate in the salt stress response, although their roles and

mechanisms remain to be elucidated. For instance, both *AtCBL5*- and *AtCBL1*-overexpressing (OE) plants showed enhanced tolerance to salt stress (Cheong, 2003; Cheong et al., 2010). Ectopic and constitutive expression of *CBL1* orthologs from the epiphytic orchid (*Sedirea japonica*), rape (*Brassica napus*), and soybean (*Glycine max*) in *Arabidopsis* also enhanced salt tolerance (Chen et al., 2012; Li et al., 2012b; Cho et al., 2018). However, the ectopic expression of *PeCBL1* in *Arabidopsis* led to salt sensitivity, with the transgenic lines not being able to exclude Na^+ under saline conditions (Zhang et al., 2013).

Tobacco (*Nicotiana tabacum*) has been investigated as a potential model crop to adapt to salt stress via various strategies (Sun et al., 2020). *N. tabacum* L. cv. Zhongyan 100 is of good salt tolerance which can survive under 300 mM NaCl in a hydroponic growth system (data not shown). In our studies on *NtCBL* members in Zhongyan 100, *NtCBL5A* attracted our attention because its overexpression broke the salt tolerance of Zhongyan 100 and led to salt supersensitivity with severe necrotic lesions on leaves. Studies on *CBL5* orthologs were only reported in *Arabidopsis*: overexpression of *AtCBL5* enhanced the salt tolerance of transgenic *Arabidopsis* (Cheong et al., 2010; Wang et al., 2013). In this study, we explored the mechanisms underlying the salt sensitivity of *NtCBL5A*-OE leaves at the physiological, biochemical, and molecular levels. Our results indicate that constitutive overexpression of *NtCBL5A* leads to Na^+ -dependent leaf necrosis by enhancing the sensitivity of transgenic tobacco leaves to Na^+ . This Na^+ sensitivity may be related to Na^+ compartmentalization, plant photosynthesis, and plant immune response.

MATERIALS AND METHODS

Plant material

N. tabacum L. cv. Zhongyan 100 was obtained from the Tobacco Research Institute of CAAS.

Plasmids construction

The coding sequence of *NtCBL5A* was first amplified from cDNA synthesized from RNA extracted from veins of tobacco cultivar Zhongyan 100 with primers NtCBL5A-1F and NtCBL5A-1R (Table S1) and cloned into the pMD19-T vector for sequencing. The *NtCBL5A* CDS was amplified from pMD19-T-NtCBL5A with primers NtCBL5A-3F-Sac I and NtCBL5A-3R-Kpn I (Table S1). The gel-purified amplicon was digested with Sac I and Kpn I and cloned into the pCHF3 vector, resulting in the binary recombinant vector pCHF3-NtCBL5A. To construct the promoter plasmid pBI101-ProNtCBL5A::GUS, the upstream sequence of the *NtCBL5A* gene was identified from scaffold Nsyl_scaffold38441 of the tobacco genome. The 2780 bp upstream regulatory region of *NtCBL5A* including promoter sequence (ProNtCBL5A; Figure S1B) was amplified from Zhongyan100 DNA using the primer pair NtCBL5Apro-1F-Sal I and NtCBL5Apro-1R-Sma I (Table S1) and cloned into a pMD19-T vector for sequencing. The promoter segment was subcloned from the pMD19-T-ProNtCBL5A construct using Sal I and Sma I into pBI101. All the constructs were confirmed by DNA sequencing by the BGI company. Confirmed constructs were transformed into *Agrobacterium tumefaciens* EHA105 for tobacco transformation.

Generation of transgenic plants

To generate the *NtCBL5A*-OE lines and *ProNtCBL5A::GUS* transgenic plants, *Agrobacterium* carrying pCHF3-NtCBL5A plasmid and pBI101-ProNtCBL5A::GUS plasmid were introduced into Zhongyan 100 respectively, by the *Agrobacterium*-mediated leaf disc transformation method (Horsch et al., 1985). To screen for *NtCBL5A*-OE lines, positive transgenic plants of the T0 generation were identified by PCR with the primers NtCBL5A-1F and pCHF3-R (Table S1). The overexpression levels of all positive plants were checked by Real-Time quantitative PCR (RT-qPCR), the RNA samples for RT-qPCR were isolated from mixed whole plants at 12 days after germination (DAG) under control conditions. Eight lines with high *NtCBL5A* overexpression of the original 17 transgenic lines (T0 generation) were selected for propagation. More than 200 T1 seeds from T0 plants with high gene overexpression

levels were harvested and subsequently screened on the selection medium (1/2 MS medium with 50 µg/ml kanamycin). All these lines show sensitivity to salt stress. Two T1 lines (OE-2 and OE-15) with a segregation of around 3:1 (tolerance: sensitivity) were selected for harvesting T2 seeds. More than 200 T2 seeds were screened on the selection medium. The T2 generation with 100% kanamycin resistance was considered as homozygous plants and used for the evaluation of stress tolerance. Positive *ProNtCBL5A::GUS* transgenic lines of the T0 generation were identified by PCR with the primers pBI101-F and NtCBL5Apro-1R-*Sma* I (Table S1). More than 200 seeds from T0 seedlings were harvested and subsequently screened on selection medium as described above and positive T1 plants from three independent lines were selected for GUS staining assay.

Application and phenotyping of salt and drought treatment

Salt and drought stress experiments were conducted in 2019 at Unifarm, Wageningen University & Research in the Netherlands. Conditions of the greenhouse were 16 h light / 8 h dark at 25/23°C and 70% relative humidity. The shortwave radiation level was maintained in the greenhouse compartment using artificial PAR (photosynthetically active radiation) when the incoming shortwave radiation was below 200 Wm⁻².

For the salt tolerance evaluations, tobacco seeds were sown in soil, and they germinated after about 8 days. About at 12 DAG, the young seedlings were transplanted in rock-wool plugs within float trays for 8 days, then they were transplanted to a circular flow hydroponic system filled with 1/2 Hoagland's nutrient solution (500 L). The water used to prepare 1/2 Hoagland's nutrient solution contained trace amounts of Na⁺ and Cl⁻ (5.04 µg/ml and 6.72 µg/ml, respectively). After 6 days of acclimatization (at ~ 30 DAG), NaCl was added to the nutrient solution to a concentration of 50 mM on the first day to avoid salt shock, and the final NaCl concentration of 100 mM NaCl was reached the next day. From 4 days after the start of the treatment (DAT), photographs of the plants were taken every day until harvest. For assessing salt tolerance, indicative traits such as growth traits (leaf width and

length, root length, fresh/dry biomass) and ion content were measured.

For the drought stress evaluation, a pilot experiment was conducted first to determine the wilting point of tobacco under the greenhouse conditions. Tobacco seeds were sown in soil. Young seedlings were transplanted to trays and pots at 12 DAG and 22 DAG. Sixteen days after transplantation to pots (38 DAG), watering was stopped until the leaves started to exhibit slight wilting, at a recorded Soil Water Content (SWC) of 28% Full Field Capacity (FFC) (~43 DAG). For the drought tolerance evaluation experiment, SWC was kept around 60% FFC (control conditions) and 28% FFC (drought conditions) by supplying a limited amount of water every day for 3 weeks (~64 DAG). The SWC was monitored and recorded with a Grodan Water Content Meter and a gravimetical method, where $SWC = (W_{wet} - W_{dry}) / FFC * 100\%$ (W_{wet} is the weight of wet soil and W_{dry} is the weight of dry soil). For assessing salt tolerance, shoot biomass and chlorophyll content were measured. Chlorophyll content was measured with the Minolta SPAD 502 Chlorophyll Meter (Ling et al., 2011). For chlorophyll content values, the average was taken of the measurements of 5 different areas of the 8th leaf (the first new leaf that appeared after the drought treatment started).

Ion and osmotic stress evaluation

For the ion and osmotic stress evaluation experiments, the plants were prepared as described for the salt evaluation experiments. The experiments were conducted in a hydroponic system filled with 1/2 Hoagland's nutrient solution in 3 L containers. The solution was refreshed every two days to keep enough nutrition and a stable stress treatment. After 6 days of acclimatization, the stress was built up in two steps: ion concentrations were raised to 50 mM NaCl/NaNO₃/KNO₃/KCl, and for the osmotic stress treatment to 8% PEG6000, and the final stress conditions were reached 100 mM NaCl/NaNO₃/KNO₃/KCl, 15% PEG6000 at the next day. Photographs of the plants were taken at 9 DAT.

Ion content measurement

Ion content measurement contained 3 biological replications and every biological replication is a pool of 3 plants. Root samples were rinsed in ddH₂O first, then were dried with absorbent paper to get rid of ions on the outside of the roots. Fresh samples were dried at 105°C until stable weights, then the dry tissue was crushed to powder with a grinder. 30~50 mg of dry sample was placed into a test tube. The powdered samples were ashed at 650°C for 6 hours. One milliliter of 3 M formic acid was added into the test tube and was shaken for 20 min at 5000 rpm at 99.9°C. Then 9 mL Milli-Q® was added into the test tube and mixed. Then 0.2 mL sample was taken out and added into 9.8 mL Milli-Q® for 50 times dilution. The ion contents of dilution samples were measured using the Ion Chromatography (IC) system 850 Professional (Metrohm Switzerland).

GUS and DAB staining

GUS staining was conducted using β -Galactosidase Reporter Gene Staining Kit (Beijing Leagene Biotech. Co., Ltd, Cat No./ID: DP0013, Beijing, China). Samples were placed into GUS staining solution and incubated at 37°C overnight. The tissues then were placed in 95% ethanol until chlorophyll was washed out, and samples were photographed. The tissues were stored in FAA (Formaldehyde-Acetic Acid-Ethanol) Fix Solution (Wuhan Servicebio Technology Co., Ltd, Cat No./ID: G1103-500 ML, Wuhan, China). For H₂O₂ visualization with DAB staining, leaves were put in 1 mg/ml DAB (3, 3'-Diaminobenzidine tetrahydrochloride hydrate) (Sigma-Aldrich, Cat No./ID: D5637-1G, Darmstadt, Germany) and vacuum infiltrated until DAB solution was taken up, after which the leaves were incubated in DAB staining solution for 16 h in the dark. The leaves were subsequently transferred to 95% ethanol for 24 h to remove chlorophyll. Afterwards, leaves were photographed (Kissoudis, 2016).

RNA isolation and RNA-seq analyses

At 4 DAT, the 5th leaf blades (with main veins removed) of four individual plants under control conditions and saline conditions in the daytime were sampled and frozen immediately in liquid nitrogen. Leaf blades from four individual plants were mixed

and ground to powder. RNA was isolated and purified with the RNeasy Plus Mini Kit (Qiagen, Cat No./ID: 74134, the Netherlands) following the manufacturer's protocol. RNA samples of WT and OE-2 overexpression lines from two independent salt treatment experiments were used for transcriptome sequencing. RNA integrity was assessed using the RNA Nano 6000 Assay Kit of the Bioanalyzer 2100 system (Agilent Technologies, CA, USA). RNA-seq was performed by the Novogene using Illumina Polymerase-based sequencing-by-synthesis, obtaining a read length of 150 bp and coverage of 48 to 81 million reads per sample. Raw reads of fastq format were firstly processed through in-house perl scripts so that all the downstream analyses were based on the clean data with high quality. Reference genome and gene model annotation files (ftp://ftp.solgenomics.net/genomes/Nicotiana_tabacum/edwards_et_al_2017/assembly/Nitab-v4.5_genome_Chromosome_Edwards2017.fasta.gz) were downloaded from NCBI. Index of the reference genome was built using Hisat2 v2.0.5 and paired-end clean reads were aligned to the reference genome using Hisat2 v2.0.5. The mapped reads of each sample were assembled by StringTie (v1.3.3b) (Pertea et al., 2015) in a reference-based approach. FeatureCounts v1.5.0-p3 was used to count the reads numbers mapped to each gene and then FPKM of each gene was calculated based on the length of the gene and read counts mapped to this gene. DEGs of two groups were performed using the DESeq2 R package (1.20.0) and resulting P-values were adjusted using the Benjamini and Hochberg's approach for controlling the false discovery rate. Genes with an adjusted P-value <0.05 found by DESeq2 were assigned as differentially expressed. ClusterProfiler R package was used to test the statistical enrichment of DEGs in KEGG pathways.

Real-time PCR and semi-quantitative RT-PCR

For RT-qPCR, RNA was reverse transcribed into cDNA using HiScript III RT SuperMix for qPCR (+g DNA wiper) (Vazyme Biotech. Co., Ltd, Cat No./ID: R323-01, Nanjing, China) and the cDNA was amplified using ChamQ Universal SYBR qPCR Master Mix (Vazyme Biotech. Co., Ltd, Cat No./ID: Q711, Nanjing, China) on the

LightCycler® 96 Instrument (F. Hoffmann-La Roche Ltd, Switzerland). All the primers used for RT-qPCR can be found in **Table S1**. The amplification reactions were performed in a total volume of 10 µl, containing 5 µl 2×ChamQ SYBR qPCR mix, 0.6 µl forward and reverse primers (10 µM), 1 µl cDNA (10 times diluted), and 3.4 µl ddH₂O. The RT-qPCR amplification program was as follows: 95°C for 10 min; 95°C for 10 s, 60°C for 30 s and amplification for 40 cycles. Each sample comprised 3 technical replications. Analysis of the relative gene expression data was conducted using the $2^{-\Delta C_t}$ (Livak and Schmittgen, 2001). For semi-quantitative RT-PCR, RNA was reverse transcribed into cDNA using iScript™ Reverse Transcription Supermix for RT-qPCR (BIO-RAD, Cat No./ID: 6031, California, USA) and cDNA was amplified using DreamTaq DNA Polymerase (Thermo Fisher Scientific, Cat No./ID: EP0702, Massachusetts, USA). The amplification reactions were performed in a total volume of 20 µl, containing 0.1 µl DreamTaq DNA polymerase, 2 µl 10×DreamTaq buffer, 0.4 µl dNTP mixture (5 mM each), 1 µl forward and reverse primers (10 µM), 2 µl cDNA, and 14.5 µl ddH₂O. The semi-quantitative RT-PCR amplification program was as follows: 95°C for 5 min; 95°C for 30 s, 52°C for 30 s, 72°C for 30 s (30 cycles); 72°C for 30 s.

Accession numbers

Sequence data from this article can be found under the following accession numbers. For genes from tobacco and *O. sativa*, sequences can be found in the NCBI database (<https://www.ncbi.nlm.nih.gov/>): *NtCBL5A* (XM_016642104.1), *NsylCBL5* (KM658159.1), *NtomCBL5* (XM_018767788.1), *OsCBL1* (DQ201195), *OsCBL2* (DQ201196), *OsCBL3* (DQ201197), *OsCBL4* (DQ201198), *OsCBL5* (DQ201199), *OsCBL6* (DQ201200), *OsCBL7* (DQ201201), *OsCBL8* (DQ201202), *OsCBL9* (DQ201203), *OsCBL10* (DQ201204). For genes from *S. lycopersicum*, sequences can be found in the SGN database (<https://solgenomics.net/>): *SICBL1* (Soly06g060980), *SICBL2* (Soly012g015870), *SICBL4-1* (Soly08g036590), *SICBL4-2* (Soly012g055920), *SICBL8* (Soly08g054570), *SICBL10* (Soly08g065330). For genes from *A. thaliana*, sequences can be found in the TAIR

database (<https://www.arabidopsis.org/>): *AtCBL1* (AT4G17615), *AtCBL2* (AT5G55990), *AtCBL3* (AT4G26570), *AtCBL4* (AT5G24270), *AtCBL5* (AT4G01420), *AtCBL6* (AT4G16350), *AtCBL7* (AT4G26560), *AtCBL8* (AT1G64480), *AtCBL9* (AT5G47100), *AtCBL10* (AT4G33000). The RNA-seq data from this article can be found in the National Center for Biotechnology Information Gene Expression Omnibus (GEO) data repository under accession number GSE181164 (<https://www.ncbi.nlm.nih.gov/geo/subs/?view=samples&series=181164>).

Statistical analysis

Statistical analysis was done using IBM SPSS Statistics 23 software. Significant differences were examined by one-way ANOVA using the LSD test at $P < 0.05$ and < 0.001 . The figures were drawn by GraphPad Prism 6.0.

RESULTS

The cloning and expression analysis of *NtCBL5A*

N. tabacum is a natural allotetraploid derived from two diploid progenitors: *N. sylvestris* as the maternal genome donor and *Nicotiana tomentosiformis* as the paternal genome donor (Yukawa et al., 2006). We predicted and cloned 12 *Nsy/CBLs* based on the *N. sylvestris* genome data published in NCBI (<https://www.ncbi.nlm.nih.gov/>) (An et al., 2020). One of these 12 *Nsy/CBLs* (NCBI reference sequence: XM_009758979.1) had the closest phylogenetic relationship with *AtCBL5* (At4g01420) and therefore was named *Nsy/CBL5* (GenBank: KM658159.1). The ortholog of *Nsy/CBL5* in *N. tabacum* L. cv. Zhongyan 100 was subsequently cloned and named *NtCBL5A* (NCBI reference sequence number: XM_016642104.1). The coding sequence (CDS) of *NtCBL5A* is identical to the CDS of *Nsy/CBL5* and has 28 nucleotide differences with the CDS of *NtomCBL5* (NCBI reference sequence number: XM_018767788.1) (Figure S1A).

The CDS of *NtCBL5A* is 642 bp in length, encoding a 213-amino-acid protein. The *NtCBL5A* protein is predicted to have four potential elongation factor hands (EF-hands) by the SMART (<http://smart.embl-heidelberg.de/>) (Letunic and Bork, 2018)

and SWISS-MODEL (<https://swissmodel.expasy.org/>) (Waterhouse et al., 2018) (Figure 1A, B). The EF-hand motif is the conserved domain of CBL proteins with an α -helix-loop- α -helix structure that binds Ca^{2+} (Sánchez-Barrena et al., 2013). A phylogenetic tree of NtCBL5A with all identified CBL proteins in *A. thaliana*, *O. sativa*, and *S. lycopersicum* distributed the CBL members over 4 clusters, and NtCBL5A was included in Cluster I with closest phylogenetic relationship to AtCBL5 (Figure 1C).

Semi-quantitative RT-PCR indicated that *NtCBL5A* is specifically expressed at a higher level in stems and a relatively lower level in main veins of young tobacco seedlings, and it is not detectable in roots and leaf blades (with main veins removed) at 30 days after germination (DAG) (Figure 2A). We examined tissue-specific expression in more detail using independent *ProNtCBL5A::GUS* transgenic tobacco lines with a 2780 bp upstream regulatory region of *NtCBL5A* including the promoter (Figure S1B) driving expression of a *GUS* reporter gene. Consistent with the semi-quantitative RT-PCR result, strong *GUS* activity was mainly detected in veins and stems of tobacco seedlings (Figure 2B-F). At 3 DAG and 20 DAG, *GUS* staining was only observed in the veins and the top of the stem (Figure 2B-D). At 40 DAG, *GUS* staining was still limited to the veins and the stem (Figure 2E, F).

Figure 1 | Structure and phylogenetic relationship of NtCBL5A. (A) Amino acid sequence of NtCBL5A and the positions of four EF-hands predicted by SMART. **(B)** The 3D structure of NtCBL5A predicted by SWISS-MODEL. **(C)** Phylogenetic analysis of NtCBL5A and all known CBL members from *A. thaliana*, *O. sativa*, and *S. lycopersicum*. The amino acid sequences of AtCBLs, OsCBLs, and SICBLs were downloaded from TAIR (<https://www.arabidopsis.org/>), NCBI (<https://www.ncbi.nlm.nih.gov/>), and Sol Genomics Network (<https://solgenomics.net/>), respectively. The phylogenetic tree was constructed by MEGA6 using the Neighbor-Joining method.

Figure 2 | The expression profile of *NtCBL5A* in tobacco plants. (A) The expression profile detection in different tissues by semi-quantitative RT-PCR at 30 days after germination (DAG), *L25* is the reference gene (Schmidt and Delaney, 2010). (B-F) The GUS staining of different tissues of *ProNtCBL5A::GUS* plants at different growth stages. They are seedlings at 3 DAG (B), seedlings at 5 DAG (C), seedlings at 20 DAG (D), leaves of the seedlings at 40 DAG (E), stem and root tissues of the seedlings at 40 DAG (F), respectively.

Overexpression of *NtCBL5A* induces salt supersensitivity with necrotic lesions on leaves

Two independent homozygous *NtCBL5A*-OE lines (OE-2, OE-15) with different overexpression levels were selected for salt tolerance evaluation (Figure 3A, B). Wild-type (WT) and *NtCBL5A*-OE lines were treated under control conditions (1/2 Hoagland's nutrient solution) and saline conditions (1/2 Hoagland's nutrient solution with 100 mM NaCl) in a hydroponic growth system. Under control conditions, there were no phenotypic differences between WT and *NtCBL5A*-OE lines. Under saline

conditions, constitutive overexpression of *NtCBL5A* led to salt supersensitivity (Figure 3C). There were leaf chlorosis spots on *NtCBL5A*-OE leaves at the early stage of salt stress that developed fast into severe necrotic lesions within two weeks (Figure 4A). In each *NtCBL5A*-OE plant, the 5th leaf that emerged just before the initiation of the salt treatment showed the most severe necrotic lesions (Figure 3C), and the occurrence of necrotic lesions started from leaf tip and leaf margin (Figure 4A). The overexpression level of *NtCBL5A* appeared to be related to the necrotic phenotype, for the OE-2 line with higher *NtCBL5A* expression level showed more severe necrotic lesions than OE-15 (Figure 4A).

Shoot dry weight and fresh weight of each tobacco line were reduced significantly under salt stress, and the reduction of *NtCBL5A*-OE lines was larger than that of WT at 9 DAT (Figure 3D, E). Under saline conditions, the length and width of the 5th *NtCBL5A*-OE leaves were more reduced with curly and narrow leaf shapes (Figure 4). In addition, ROS accumulation in the 5th *NtCBL5A*-OE leaves was higher than that in WT leaves under salt stress at 2 DAT and 6 DAT (Figure S2; Figure 4D). Root lengths of *NtCBL5A*-OE lines and WT were similarly affected by salinity, but root fresh weight was reduced more in the *NtCBL5A*-OE lines than in WT at 9 DAT (Figure S3).

Figure 3 | The detection of *NtCBL5A* expression and above-ground phenotype of wild-type (WT) and *NtCBL5A*-overexpressing (OE) lines (OE-2 and OE-15) under control conditions and salt stress (100 mM NaCl). Scale bars=10 cm. **(A)** Relative expression analysis of endogenous *NtCBL5A* (the *NtCBL5A* driven by 35S promoter) determined by RT-qPCR in different tissues of tobacco seedlings at 4 days after the start of treatment (DAT). The expression of *NtCBL5A* is relative to the reference gene *L25* and the seedlings are 30-DAG (days after germination) old. **(B and C)** Relative expression analysis of endogenous *NtCBL5A* and exogenous *NtCBL5A* (the *NtCBL5A* driven by its own promoter in tobacco) determined by RT-qPCR in whole plants. The expression of *NtCBL5A* is relative to the reference gene *L25* and the seedlings are 12-DAG old. The reverse primer pCHF3-Allcheck-1 used for amplifying exogenous *NtCBL5A* was designed according to the sequence of the overexpression vector pCHF3, referring to pCHF3-Allcheck-2 (Shi et al., 2021). **(D)** The shoot phenotype of WT and *NtCBL5A*-OE lines at 9 DAT. **(E and F)** The shoot fresh weight and dry weight of WT and *NtCBL5A*-OE lines at 9 DAT. Error bars indicate \pm SD (n=3 for gene expression detection, n=17 for shoot fresh/dry weight determination),

Error bars indicate \pm SD ($n=17$), different letters above bars (a,

b, and c) indicate significant statistical difference based on one-way ANOVA with LSD test ($P < 0.05$). Scale bars=2 cm.

The necrotic lesions are specifically induced by high Na^+ in the nutrient solution

The response to the osmotic component of salt stress bears similarity to the response to drought (Bartels and Sunkar, 2005). Therefore, the effect of drought stress on *NtCBL5A*-OE plants was determined as well. WT and *NtCBL5A*-OE lines were exposed to drought stress in pots under greenhouse conditions. At 21 DAT, all the lines showed reduced growth compared to the control plants with no water limitation, but there were no significant phenotype differences between the WT and *NtCBL5A*-OE plants under drought stress (Figure 5A). Under drought stress, plant height, fresh and dry shoot weight of each line were decreased, while chlorophyll content of each line was significantly increased compared to control conditions (Figure 5B-E). There were no differences between WT and *NtCBL5A*-OE lines under drought stress (Figure 5B-E), suggesting that osmotic stress alone did not trigger necrotic lesions on *NtCBL5A*-OE leaves. A 15% PEG6000 treatment was conducted to confirm that the necrotic lesions on transgenic lines are not caused by osmotic stress. Indeed, the PEG6000-induced osmotic stress did not induce leaf necrosis in OE-2 and OE-15 lines (Figure 6B).

Under saline conditions, both Na^+ and Cl^- can be toxic to the plant (Munns et al., 2008). To identify the ion that is responsible for the necrotic phenotype of *NtCBL5A*-OE lines under salt stress, the plants were exposed not only to 100 mM NaCl, but also to 100 mM NaNO_3 , 100 mM KNO_3 , and 100 mM KCl (Quan et al., 2007). At 9 DAT, both WT and *NtCBL5A*-OE lines exhibited reduced growth under all treatments relative to control conditions (Figure 6). *NtCBL5A*-OE lines showed leaf necrosis only under NaCl and NaNO_3 treatments but not under KNO_3 and KCl treatments (Figure 6C-F), suggesting that the necrotic lesions on *NtCBL5A*-OE lines are specifically induced by high levels of Na^+ in the nutrient solution.

Figure 5 | Phenotypic analysis of wild-type (WT) and *NtCBL5A*-overexpressing (OE) lines (OE-2 and OE-15) under control conditions and drought stress. Scale bars=30 cm. **(A)** The phenotype of WT and *NtCBL5A*-OE lines under control conditions and drought stress at 21 days after the start of treatment (DAT) and 64 days after germination (DAG). **(B)** The chlorophyll content of the 8th leaf of WT and *NtCBL5A*-OE lines from 3 DAT to 21 DAT. **(C-E)** The plant height, fresh shoot biomass, and dry shoot biomass of WT and *NtCBL5A*-OE lines at 21 DAT. Error bars indicate \pm SD (n=4), different letters above bars (a, b, and c) indicate significant statistical difference based on one-way ANOVA with LSD test ($P<0.05$).

Overexpression of *NtCBL5A* enhances the sensitivity of transgenic tobacco leaves to Na⁺

To elucidate the cause of the salt-induced necrotic lesions in *NtCBL5A*-OE leaves, we measured the ion contents in the 5th leaf blades (with main veins removed) of all tobacco lines at three treatment time points (4, 6, 9 DAT). It needs to mention first that there was no significant difference between leaf water contents of WT and *NtCBL5A*-OE (Figure S4A). Na⁺ contents in the 5th leaf blades of all lines were strongly increased under salt stress relative to control conditions and increased with treatment time. Compared to WT, Na⁺ contents in the 5th leaf blades of *NtCBL5A*-OE lines were higher under salt stress but the difference was not large (Figure 7A).

More specifically, during the 4~9 DAT, the Na^+ contents in the 5th leaf blades of WT, OE-2, and OE-15 tobacco plants are in the range of 39.18~51.64 $\mu\text{g}/\text{mg}$, 44.95~69.71 $\mu\text{g}/\text{mg}$, and 47.36~64.31 $\mu\text{g}/\text{mg}$, respectively. In other words, the 5th leaf blades of WT lines could reach a similar Na^+ content level to that of OE lines with treatment time, but they did not exhibit any necrotic lesions at all during the treatment period (Figure 7A; Figure 4A). Cl^- contents in the 5th leaf blades of all lines were strongly increased under salt stress relative to control conditions and increased with time, but there was no significant difference between WT and *NtCBL5A*-OE lines under salt stress (Figure 7C). K^+ , Ca^{2+} , and Mg^{2+} contents in all lines were significantly decreased under salt stress but also for these ions there was still no significant difference between WT and *NtCBL5A*-OE plants (Figure S4B-D).

We also measured the Na^+ and Cl^- contents in different tissues (leaf blades: all leaves with main veins removed; main veins: main veins from all leaves; stems; roots) of all lines under control conditions and 100 mM NaCl stress at 10 DAT. Under salt stress, Na^+ contents in all tissues of all lines were strongly increased relative to control conditions, and Na^+ contents in leaf blades of *NtCBL5A*-OE lines were significantly higher than those of WT (Figure 7B). In contrast, Na^+ contents in main veins, stems, and roots of OE-2 and OE-15 were significantly lower than those of WT under salt stress (Figure 7B). Cl^- contents in all tissues of all lines were strongly increased under salt stress relative to control conditions but there was no significant difference between different lines (Figure 7D). Taken together, ion content data suggested that the overexpression of *NtCBL5A* may promote Na^+ loading into leaf blades, but the necrotic lesions are caused by the increased Na^+ sensitivity of *NtCBL5A*-OE leaves.

Figure 7 | Na^+ and Cl^- contents in wild-type (WT) and *NtCBL5A*-overexpressing lines (OE-2 and OE-15) under control conditions and salt stress (100 mM NaCl). (A and C), Na^+ and Cl^- contents in the 5th leaf blades (with main veins removed) at 4 DAT, 6 DAT, and 9 DAT. (B and D) Na^+ and Cl^- contents in different tissues (leaf blades: all leaves with main veins removed; main veins: main veins from all leaves; stems; roots) at 10 DAT. C means control conditions, while S means salt stress. Error bars indicate \pm SD ($n=3$), every biological replication is a mixed pool of 3 plants. One-way ANOVA with LSD test (* $P<0.05$ and ** $P<0.01$) was used to analyze statistical significance.

Differentially expressed genes (DEGs) in *NtCBL5A*-OE leaves under salt stress were analyzed

To further identify the genes and pathways involved in the necrotic phenotype of *NtCBL5A*-OE lines, the leaf transcriptome profiling of WT and OE-2 lines grown under control conditions and salt stress (100 mM NaCl) at 4 DAT were sequenced and compared. Two datasets of differentially expressed genes (DEGs) were made in which we identified the genes that were differentially expressed as a result of the overexpression of *NtCBL5A*: Control-WT vs Control-OE2 (C-WT/C-OE2), Salt-WT vs Salt-OE2 (S-WT/S-OE2). Another two datasets were also used to identify the transcripts that were responsive to the salt treatments: Control-WT vs Salt-WT (C-WT/S-WT) and Control-OE2 vs Salt-OE2 (C-OE2/S-OE2). DEGs from C-WT/C-OE2

and S-WT/S-OE2 were compared to select the transcripts affected by *NtCBL5A* overexpression only under salt stress (dotted lines in Figure 8A, D; Figure S5). We also compared DEGs from C-WT/S-WT and C-OE2/S-OE2 to identify the specific transcripts affected by salt stress and only in *NtCBL5A*-OE lines (dotted lines in Figure 8B, E; Figure S5). This procedure was done for two independent experiments, and only DEGs that were identified in both experiments were considered (highlighted part in Figure 8A, B, D, E). The OE-affected DEGs and salt-affected DEGs together resulted in 2079 up-regulated DEGs and 1154 down-regulated DEGs (Figure 8C, F), strongly affected by the combination of *NtCBL5A* overexpression and salt stress.

The up-regulated DEGs were enriched in 10 KEGG (Kyoto encyclopedia of genes and genomes) (Kanehisa et al., 2020) pathways ($\text{padj} < 0.05$) (Figure 8G). Among them, “plant-pathogen interaction” (KEGG ID: sly04626) and “MAPK signaling pathway-plant” (KEGG ID: sly04016) attracted our attention because many DEGs identified as belonging to these two pathways are related to HR and cell death, including *PATHOGENESIS RELATED PROTEIN 1a* (*PR1a*), *PR1b*, *PR1c*, *PR-Q*, *PR-R* major form, *PR-R* minor form, *ETHYLENE RESPONSE FACTOR 1* (*ERF1*), *ENHANCED DISEASE SUSCEPTIBILITY 1* (*EDS1*, SA-related signal transducers), and *RPM1-INTERACTING PROTEIN 4* (*RIN4*). Besides, Ca^{2+} channels *CYCLIC NUCLEOTIDE-GATED ION CHANNEL* (*CNGC*) and other two types of Ca^{2+} -sensor genes *CML* and *CDPK* were also enriched in the MAPK signaling pathway-plant. Interestingly, these genes are highly up-regulated only under the combination of *NtCBL5A* overexpression and salt stress. The down-regulated DEGs were enriched in 4 KEGG pathways ($\text{padj} < 0.05$) (Figure 8H). In “photosynthesis” (KEGG ID: sly00195) and “photosynthesis-antenna proteins” (KEGG ID: sly00196) pathways, many genes related to photosystem I (e.g., *PsaD*, *PsaH*, and *PsaE*), photosystem II (e.g., *PsbD*, *PsbQ*, and *PsbW*), photosynthetic electron transport (*PetE*, *PetF*, and *PetH*), and light-harvesting chlorophyll protein complex (e.g. *Lhca1-5*, *Lhcb1*, and *Lhcb3-6*) were significantly down-regulated.

Figure 8 | The analysis of leaf transcriptome data of wild-type (WT) and the *NtCBL5A*-overexpressing line (OE-2) at 4 DAT. (A) Venn diagram with four up-regulated gene sets: Experiment 1 (Exp1)-C-WT/C-OE2, Exp 1-S-WT/S-OE2, Exp 2-C-WT/C-OE2, and Exp 2-S-WT/S-OE2. **(B)** Venn diagram with four up-regulated gene sets: Exp1-C-WT/S-WT, Exp 1-C-OE2/S-OE2, Exp 2-C-WT/S-WT, and Exp 2-C-OE2/S-OE2. **(C)** Venn diagram with two sets: OE-affected up-regulated DEGs and Salt-affected up-regulated DEGs. **(D)** Venn diagram with four down-regulated gene sets: Exp 1-C-WT/C-OE2, Exp 1-S-WT/S-OE2, Exp 2-C-WT/C-OE2, and Exp 2-S-WT/S-OE2. **(E)** Venn diagram with four down-regulated gene sets: Exp 1-C-WT/S-WT, Exp 1-C-OE2/S-OE2, Exp 2-C-WT/S-WT, and Exp 2-C-OE2/S-OE2. **(F)** Venn diagram with two sets: OE-affected down-regulated DEGs and Salt-affected down-regulated DEGs. **(G and H)** KEGG enrichment of up-regulated genes and down-regulated genes. The pathways labeled in blue were significantly enriched pathways. Count: the number of DEGs, bigger circle means more DEGs number; GeneRatio: the number of DEGs / the total number of genes in this pathway;

padj: P-value, padj<0.05 means significant difference, redder color means greater significance. The raw data of RNA-seq can be found in GEO data repository with the accession number GSE181164, in which samples were named as C-WT-1, S-WT-1, C-OE2-1, S-OE2-1, C-WT-2, S-WT-2, C-OE2-2, S-OE2-2. “C” refers to “Control”, “S” refers to “Salt”, “WT” refers to “wild-type”, “OE2” refers to the OE2 line of *NtCBL5A*-overexpressing lines, “1” refers to “Experiment 1”, and “2” refers to “Experiment 2”.

Plant defense- and cation homeostasis-related genes are regulated in *NtCBL5A*-OE leaves under salt stress

Under salt stress, *NtCBL5A*-OE leaves exhibited necrotic lesions that bear resemblance to hypersensitive reaction (HR)-like cell death in plant response to pathogen infection. To understand the causes of the necrotic lesions, we specifically examined the expression of the HR marker genes *N-RICH PROTEIN (NRP)* (Ludwig and Tenhaken, 2001) and *HYPERSENSITIVE-RELATED 203J (hypersensitive-related 203J)* (Pontler et al., 1994), as well as the plant defense-related genes in the “Plant-pathogen interaction” pathway and “MAPK signaling pathway-plant” pathway (Figure 8G). *NPR* and *HSR203J* genes were strongly up-regulated in *NtCBL5A*-OE leaves under salt stress (Figure 9A, B). In addition, the expression levels of plant defense-related genes like *PR* genes (*PR1a*, *PR1b*, *PR1c*, *PR-Q*, and *PR-R*) (Sinha et al., 2014), *EDS1* (Lapin et al., 2020), *RIN4* (Ray et al., 2019), *ERF1* (Lorenzo et al., 2003), and *CATALASE 1 (CAT1)* (Tran and Jung, 2020) were much higher in *NtCBL5A*-OE leaves than those in WT leaves under salt stress (Figure 9C-H; Figure S6A-D). Taken together, these data suggested that salinity stress activates an immunity-related response specifically in the *NtCBL5A*-OE lines.

Under saline conditions, Na⁺ accumulation in *NtCBL5A*-OE leaves was slightly higher than that in WT leaves (Figure 7A). Therefore, we hypothesized that *NtCBL5A* overexpression may affect the expression of several cation homeostasis-related genes involved in salt stress response. Based on the transcriptome analysis, several genes required for K⁺, Na⁺, and Ca²⁺ homeostasis were significantly up- or down-regulated by combined condition of *NtCBL5A* overexpression and salt stress. The

expression profile of these genes was validated by RT-qPCR. *Cation/H⁺ EXCHANGER 18 (CHX18)* and *Na⁺/Ca²⁺ EXCHANGER 1 (NCX1)* gene were strongly up-regulated (Figure 9 I, J), while *vacuolar CATION/PROTON 3 (CAX3)* gene involved in ion vacuolar compartmentalization (Martinoia et al., 2007; Zhao et al., 2007) was down-regulated in WT and even more strongly inhibited in *NtCBL5A*-OE lines under saline conditions (Figure 9K). In addition, the expression of Ca²⁺ channels *CNGC1* was up-regulated in *NtCBL5A*-OE leaves under saline conditions (Figure 9L). The results of RT-qPCR were consistent with the transcriptome data and indicated that *NtCBL5A* overexpression greatly affects the expression of cation homeostasis-related genes under salt stress.

Figure 9 | Relative expression analysis of plant defense-related marker genes, Na⁺ homeostasis- and Ca²⁺ homeostasis-related genes determined by RT-qPCR in tobacco leaves. (A-L) The expression of these genes are relative to the reference gene *L25* under control conditions and salt stress (100 mM NaCl) at 4 days after the start of treatment. Their gene IDs in the reference tobacco genome database (ftp://ftp.solgenomics.net/genomes/Nicotiana_tabacum/edwards_et_al_2017/assembly/Nitab-

v4.5_genome_Chromosomes2017.fasta.gz) are *NRP* (Nitab4.5_0000798g0120), *HSR203J* (Nitab4.5_0002719g0120), *PR-Q* (Nitab4.5_0003207g0080), *PR1a* (Nitab4.5_0003771g0010), *PR1b* (Nitab4.5_0005400g0020), *PR1c* (Nitab4.5_0004861g0040), *PR-R* minor (Nitab4.5_0004097g0050), *PR-R* major (Nitab4.5_0000360g0100), *CHX18* (Nitab4.5_0006998g0030), *NCX1* (Nitab4.5_0005404g0030), *CAX3* (Nitab4.5_0000102g0080), *CNGC1* (Nitab4.5_0000258g0120). Error bars indicate \pm SD (n=3). One-way ANOVA with LSD test (*P<0.05, **P<0.01) was used to analyze statistical significance.

Photosynthetic machinery-related genes are strongly inhibited in *NtCBL5A*-OE leaves under salt stress

Under salt stress, *NtCBL5A*-OE leaves exhibited chlorotic spots developing into necrotic lesions from 4 DAT (Figure 4A). To gain further insight into the causes of the chlorotic spots, we examined the expression levels of the photosynthesis essential genes in the “Photosynthesis” pathway and “Photosynthesis-antenna proteins” pathway (Figure 8H). *PsaH*, *PsaE*, and *PsaD* in photosystem I; *PsbQ*, *PsbX*, and *OXYGEN EVOLVING ENHANCER PROTEIN 1 (OEE1)* in photosystem II; *LIGHT-HARVESTING CHLOROPHYLL PROTEIN COMPLEX (Lhca3, Lhcb3, and Lhcb4)*; *FERREDOXIN (Fd)* in photosynthetic electron transport; *F-ATPase delta subunit*; and *GLYCERALDEHYDE-3-PHOSPHATE DEHYDROGENASE A (GAP)* in Calvin cycle were examined, RT-qPCR results showed that their expression in both WT and *NtCBL5A*-OE leaves were significantly inhibited by salinity at 4 DAT (Figure 10). More importantly, their expression levels in *NtCBL5A*-OE leaves were significantly lower than that in WT leaves under salt stress (Figure 10). These data suggested that the photosynthetic machinery might be more severely affected in *NtCBL5A*-OE leaves than in WT leaves under salt stress at 4 DAT.

Figure 10 | Relative expression analysis of photosynthesis-related genes determined by RT-qPCR in tobacco leaves. (A-L) The expression of these genes are relative to the reference gene *L25* under control conditions and salt stress (100 mM NaCl) at 4 days after the start of treatment (DAT). Their gene IDs in the reference tobacco genome database (ftp://ftp.solgenomics.net/genomes/Nicotiana_tabacum/edwards_et_al_2017/assembly/Nitab4.5_genome_Chromosome_Edwards2017.fasta.gz) are *PsaH* (Nitab4.5_0000351g0060), *PsaE* (Nitab4.5_0000385g0230), *PsaD* (Nitab4.5_0014875g0010), *PsbQ* (Nitab4.5_0002345g0070), *PsbX* (Nitab4.5_0000073g0060), *OEE1* (Nitab4.5_0000108g0110), *Lhca3* (Nitab4.5_0000923g0200), *Lhcb3* (Nitab4.5_0012832g0010), *Lhcb4* (Nitab4.5_0011597g0020), *Fd* (Nitab4.5_0004129g0010), *F-ATPase delta subunit* (Nitab4.5_0006745g0030), *GAPA* (Nitab4.5_0010299g0040). Error bars indicate \pm SD ($n=3$). One-way ANOVA with LSD test (* $P<0.05$, ** $P<0.01$) was used to analyze statistical significance.

DISCUSSION

The mechanisms of salt stress response have been the subject of many research studies. A lot of candidate genes involved in salt stress response have been identified, including genes responsible for sensing and signaling in roots,

photosynthesis, Na^+ accumulation in shoots and vacuoles, and accumulation of organic solutes (Munns et al., 2008). However, actual improvements to salt tolerance in crops have been limited, partially because salt tolerance is a polygenic trait controlled by quantitative loci (Ismail and Horie, 2017). Therefore, more pathway components in the salt stress response need to be explored. The strategy of generating a phenotype by targeted overexpression can be used as a powerful tool to identify the potential response pathway components (Prelich, 2012). In this study, constitutive overexpression of *NtCBL5A* greatly interferes with the normal salt stress response of tobacco and induces Na^+ -dependent salt supersensitivity with necrotic lesions on leaves. Analysis of this phenotype generated by *NtCBL5A* overexpression may provide insight into genes and relatively poorly explored pathways that are involved in the salt stress response of plants.

CBL-CIPK complexes act as important nodes in the plant signaling cascade, linking environmental stimuli with multiple biochemical and physiological responses. $[\text{Ca}^{2+}]_{\text{cyt}}$ triggered by salinity stress can be sensed by CBLs (Perochon et al., 2011). One CBL can interact with different CIPKs and each CIPK may phosphorylate diverse targets (Ma et al., 2020). Therefore, constitutive overexpression of a *CBL* gene may generate a cascade effect, overreacting to the $[\text{Ca}^{2+}]_{\text{cyt}}$ transients triggered by salinity stress and leading to unexpected phenotypes. To elucidate the mechanisms underlying the necrotic phenotype, the *NtCBL5A*-OE lines were evaluated at the physiological, biochemical, and molecular levels. We found that the necrotic phenotype was uniquely induced by high levels of Na^+ rather than Cl^- and osmotic stress in the nutrient solution. Many genes related to cation homeostasis, plant immunity, and the photosynthetic machinery were affected at the transcriptional level in *NtCBL5A*-OE leaves under salt stress. The constitutive overexpression of *NtCBL5A* may make more potential pathway components in salt stress response detectable.

Constitutive overexpression of *NtCBL5A* may interfere with the network responsible for tobacco tolerance

Under saline conditions, plants suffer from Na^+ toxicity due to Na^+ accumulation in the leaves (Munns et al., 2008). Generally, Na^+ can accumulate to toxic concentrations earlier in old leaves than in younger growing leaves because the old leaves no longer expand and so no longer dilute the salt (Munns et al., 2008). In addition, basal zones of leaf blades accumulate more ions than tip zones because the dehydration process starts at the leaf tip (de Lacerda et al., 2003). Inconsistent with the normal pattern of Na^+ accumulation in plants, however, the 5th leaf of *NtCBL5A*-OE tobacco developed the earliest and most severe necrotic lesions in this study (Figure 3C) and the occurrence of necrotic lesions started from leaf tip and leaf margin (Figure 4A). Ion content determination provides us with more information about the necrotic lesions. Although the severe necrotic lesions occurring on *NtCBL5A*-OE leaves were Na^+ -dependent, their total Na^+ accumulation was only slightly higher than that of WT leaves. The difference in Na^+ concentrations is statistically significant but not large. Specifically, during 4~9 DAT, the Na^+ contents in the 5th leaves of WT, OE-2, and OE-15 are in the range of 39.18~51.64 $\mu\text{g}/\text{mg}$, 44.95~69.71 $\mu\text{g}/\text{mg}$, and 47.36~64.31 $\mu\text{g}/\text{mg}$, respectively (Figure 7A). The 5th leaves of WT plants remained green with Na^+ accumulating up to 51.64 $\mu\text{g}/\text{mg}$, while *NtCBL5A*-OE lines exhibited obvious chlorotic spots or necrotic lesions with a similar level of Na^+ accumulation in their leaves (Figure 4A; Figure 7A). Taken the phenotypic analysis and Na^+ determination together, it is possible that the distribution of Na^+ over different tissues and cell organelles was affected by *NtCBL5A* overexpression. We did find the expression of several cation homeostasis-related genes such as *CHX18*, *NCX1*, and vacuolar *CAX3* were regulated in salt-stressed *NtCBL5A*-OE leaves (Figure 9). To sum up, the compromised Na^+ -handling ability and Na^+ homeostasis may contribute more to the formation of necrotic lesions on *NtCBL5A*-OE leaves.

Overexpression phenotypes often result from competition-based mechanisms

(Prelich, 2012). The necrotic phenotype may result from the interference of ectopically expressed *NtCBL5A* with other components of the CBL-CIPK network that are important in the salt stress response of tobacco. CBL members with close phylogenetic relationships were shown to be able to interact with the same CIPK. Both AtCBL1 and AtCBL9 interact with AtCIPK23 to regulate K⁺ uptake under low-potassium conditions by activating K⁺ transporters (Li et al., 2006; Aleman et al., 2011; Ragel et al., 2015). In addition, AtCBL2 and AtCBL3 both interact with AtCIPK12 as crucial regulators of vacuole dynamics (Steinhorst et al., 2015), and work with AtCIPK3/9/23/26 at the tonoplast to sequester Mg²⁺ into vacuole to avoid high Mg²⁺ toxicity (Tang et al., 2015). Some CBL family members are supposedly able to compete for the same CIPK member, but they are “spatially isolated” because of different subcellular localization or tissue-specific expression. For example, both AtCBL4 and AtCBL10 interact with AtCIPK24 to regulate Na⁺ homeostasis under salt stress, but the AtCBL4-AtCIPK24 complex mainly works in roots for Na⁺ exclusion, the AtCBL10-AtCIPK24 complex mainly works in shoots for Na⁺ efflux or compartmentalization (Kim et al., 2007; Lin et al., 2009). This cooperation or competition of CBL family members suggests that ectopically expressed *NtCBL5A* might compete with other NtCBLs for the same NtCIPK and interfere with their functions, for instance with the NtCBL-NtCIPK complex that is regulating Na⁺ vacuolar compartmentalization and thus affect Na⁺ sequestration into the vacuole. As a result, Na⁺ might be less efficiently compartmentalized in vacuole, increasing the toxicity of Na⁺ in the cytoplasm. This would be in agreement with our hypothesis that the Na⁺ sensitivity of the *NtCBL5A*-OE lines under saline conditions might be partly caused by compromised distribution of Na⁺ within the leaves. This hypothesis can be verified by co-overexpression of *NtCBL5A* and its competing *NtCBL*, which may reverse the necrotic phenotype of *NtCBL5A*-OE leaves (Prelich, 2012).

The Na⁺ sensitivity of *NtCBL5A*-OE leaves may be related to defective photosystems and ROS

Both transcriptome analyses and RT-qPCR results indicated that the expression of

photosynthesis-related genes in *NtCBL5A*-OE leaves were significantly inhibited by salinity at 4 DAT (Figures 8H and 10), which is consistent with the dotted chlorosis phenotype at this time point (Figure 4A). To understand whether photosynthesis dysfunction is related to the salt-induced necrotic phenotype of *NtCBL5A*-OE leaves, we examined the expression levels of photosynthesis-related genes at very early stages of salt treatment (1 DAT and 2 DAT) when there were no chlorotic spots or necrotic lesions in *NtCBL5A*-OE leaves. RT-qPCR results showed that their expression levels in *NtCBL5A*-OE leaves were lower than those in WT already at 1 DAT (Figure S6E-P), which suggests that the photosynthetic machinery of *NtCBL5A*-OE leaves may be affected shortly after the start of salt treatment.

It has been reported that some leaf lesion-mimic phenotypes are connected to defective photosystems (Zulfugarov et al., 2014; Bruggeman et al., 2015; Wang et al., 2015; Tang et al., 2020). Light energy input exceeds energy utilization when CO₂ assimilation and NADP⁺ regeneration in the Calvin cycle are inhibited by salinity-induced stomatal limitation, leading to overreduction of the electron transport chain and the generation of ROS (Attia et al., 2009; Hajiboland, 2014). If the capacity of the ROS scavenging system is not sufficient, excessive ROS will accumulate and lead to damage. The ROS accumulation in *NtCBL5A*-OE leaves was higher than that in WT under salt stress already at 2 DAT and 6 DAT (Figure S2; Figure 4D). Possibly, the light energy input in *NtCBL5A*-OE leaves exceeds energy utilization when the Calvin cycle is more inhibited than light reaction in the photosynthesis of *NtCBL5A*-OE leaves under salt stress, and the resulting ROS generation in *NtCBL5A*-OE leaves might be beyond the ROS scavenging ability and lead to the necrotic lesions.

The question then remains that how overexpression of *NtCBL5A* in combination with high Na⁺ in the root environment triggers excess ROS production and affects the photosynthetic machinery. It is remarkable that the expression of photosynthetic machinery-related genes already changed at 1 DAT, ROS appeared to be already elevated at 2 DAT, and chlorotic symptoms developed quickly after the start of salt treatment. This might indicate that the salt supersensitivity is initiated already during

the early salinity response of the plant. Although it is generally accepted that the first response to salt stress in plants is triggered by the osmotic stress component of salinity, recent studies indicated that plants also specifically sense the presence of high Na^+ in the soil at the early stages of salt stress (Lamers et al., 2020; Van Zelm et al., 2020). This triggers Ca^{2+} waves in the roots that even reach the leaves (Choi et al., 2014). Additionally, ROS are rapidly activated (Miller et al., 2010). Members of the CBL-CIPK signaling network may play a role in the translation of the second messenger Ca^{2+} (Manishankar et al., 2018), and the AtCBL1/9-AtCIPK26 complex was shown to be able to interact with AtRbohF which is a member of the ROS burst-regulating Rboh gene family (Drerup et al., 2013). It is therefore conceivable that ectopic and constitutive overexpression of *NtCBL5A* may interfere with the Ca^{2+} and ROS-mediated response of plants following early sensing of high Na^+ levels in the root environment. Further exploration of the reason for necrotic lesions on *NtCBL5A*-OE leaves might help to gain insight into this early Na^+ response of plants as part of the response to salinity, and the crosstalk between the salt stress response and photosynthesis.

The Na^+ sensitivity of *NtCBL5A*-OE leaves may be related to plant immune response

Transcriptome analysis provided additional information on cause of the fast-developing necrotic symptoms of *NtCBL5A*-OE tobacco. The expression of cell death- and immune response-related genes were induced in *NtCBL5A*-OE leaves under salt stress. These included NRP and HSR203J, which are immunity-related cell death HR marker genes that are activated as part of the plant disease defense and execution of the cell death programme (Ludwig and Tenhaken, 2001). In addition, many plant defense-related genes like PR genes, ERF1, EDS1, and RIN4 were also specifically strongly up-regulated in *NtCBL5A*-OE lines under saline conditions (Figure 9A-H; Figure S6A-D), suggesting that PAMP- and effector-triggered responses are induced in *NtCBL5A*-OE leaves under salt stress. The CBL-CIPK network has been widely reported to be involved in HR-related plant immunity to

pathogens, such as SICBL10-SICIPK6 (Gutiérrez-Beltrán et al., 2017), AtCIPK6 (Sardar et al., 2017), OsCIPK15 (Kurusu et al., 2010), CaCIPK1 (Ma et al., 2019), TaCBL4-TaCIPK5 (Liu et al., 2018), TaCIPK10 (Liu et al., 2019), and MeCBL1/9-MeCIPK23 (Yan et al., 2018). Moreover, Cassava MeCBL1/9-MeCIPK23 positively regulates plant's defense against *Xanthomonas axonopodis* pv. *manihotis* via affecting the expression of defense-related genes including PR1, PR2, PR5, and NPR1 (nonexpresser of PR genes 1) (Yan et al., 2018). Crosstalk between the response to abiotic and biotic stress and the role of plant immune-related genes in this crosstalk has been shown by others (Nejat and Mantri, 2017; Saijo and Loo, 2020), and it is possible that some plant immune-related DEGs in *NtCBL5A*-OE leaves under salt stress might be involved in the combined salt stress and biotic stress response.

CONFLICT OF INTEREST STATEMENT

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

AUTHOR CONTRIBUTIONS

J.M. conceived the original research plans, performed the experiments, and analyzed the data; H.L., Q.W., and C.G.V.L. co-supervised the experiments; A.L. generated *ProNtCBL5A::GUS* transgenic tobacco lines; J.Y. and Z.M. provided technical assistance to J.M.; S.S. generated *NtCBL5A*-OE lines in T0 generation; J.M. conceived the project and wrote the article with contributions of all the authors; Y.S. and G.L. helped with manuscript revision; R.G.F.V., Y.B., H.L., Q.W., and C.G.V.L. supervised and completed the writing. H.L. and Q.W. agrees to serve as the authors responsible for contact and ensures communication. All authors contributed to the article and approved the submitted version.

FUNDING

This work was supported by the Fundamental Research Funds for China Agricultural

Academy of Sciences (1610232021002), the Agricultural Science and Technology Innovation Program (ASTIP-TRIC02, ASTIP-TRIC03), China Scholarships Council (CSC No. 201803250083), International Foundation of Tobacco Research Institute of CAAS (IFT202102), and International Exchange Scholarship of the GSCAAS.

ACKNOWLEDGMENTS

We would like to acknowledge the support of the PhD Education Programs between The GSCAAS and WUR. We would like to thank Dr. Pádraic Flood from Plant Breeding, WUR for critically reading the manuscript; Geurt Versteeg and Sean Geurts from Unifarm of WUR for helps on plant caring; Prof. Yi Shi, Prof. Yongfeng Guo, Prof. Aiguo Yang, Dr. Yiting Li, and Mengmeng Cui from Tobacco Research Institute of CAAS for technical support; Sri Sunarti from Plant Breeding of WUR and interns Chong Zhang from Jining Medical University for experimental assistance.

Start codon

Figure S1 | The coding sequence alignment of *NtCBL5A*, *N. sylvestris CBL5* (*Nsy/CBL5*), and *N. tomentosiformis CBL5* (*NtomCBL5*) (A) and the cloned upstream regulatory region of *NtCBL5A* (B).

Figure S2 | DAB staining of tobacco under control conditions and salt stress (100 mM NaCl) at 2 DAT.

Figure S3 | Root phenotype (A), root length (B), and root fresh weight (C) of wild-type (WT) and *NtCBL5A*-overexpressing lines (OE-2 and OE-15) under control conditions and salt stress (100 mM NaCl) at 9 DAT. Scale bar=10 cm. Error bars indicate \pm SD (n=17), different letters above bars (a, b, and c) indicate significant statistical difference based on one-way ANOVA with LSD test (P<0.05).

Figure S4 | Leaf water content and K⁺, Ca²⁺, Mg²⁺ determination. (A) Leaf water content of wild-type (WT) and *NtCBL5A*-overexpressing lines (OE-2 and OE-15) under control conditions and salt stress (100 mM NaCl) at 9 DAT. Leaf water content (%) = $(W_{\text{fresh}} - W_{\text{dry}}) / W_{\text{fresh}} \times 100\%$ (W_{fresh} is the leaf fresh weight and W_{dry} is the leaf dry weight). Error bars indicate \pm SD (n=17). (C-D) K⁺, Ca²⁺, and Mg²⁺ contents in the 5th leaf (without main vein) of WT and *NtCBL5A*-OE lines under control conditions and salt stress (100 mM NaCl) at 4 DAT, 6 DAT, and 9 DAT. C means control conditions, while S means salt stress. Error bars indicate \pm SD (n=3), every biological replication is a mixed pool of 3 plants. One-way ANOVA with LSD test (*P<0.05 and **P<0.01) was used to analyze statistical significance.

Figure S5 | The flow of OE-affected DEGs (A) and Salt-affected DEGs analysis (B). The read color indicates the "Treatment Group" relative to "Control Group" for transcriptome analysis.

Figure S6 | Relative expression analysis of immunity-related genes and photosynthesis-related genes to reference gene *L25* by RT-qPCR. (A-D) Gene expression analysis of immunity-related genes at 4 DAT under control conditions and salt stress (100 mM NaCl). **(E-P)** Gene expression analysis of photosynthesis-related genes at 1 DAT and 2 DAT under salt stress (100 mM NaCl). Their gene IDs in the reference tobacco genome database (ftp://ftp.solgenomics.net/genomes/Nicotiana_tabacum/edwards_et_al_2017/assembly/Nitab-v4.5_genome_Chrr_Edwards2017.fasta.gz) are *EDS1* (Nitab4.5_0002101g0050), *RIN4* (Nitab4.5_0003020g0010), *ERF1* (Nitab4.5_0010541g0010), *CAT1* (Nitab4.5_0009821g0010), *PsaH* (Nitab4.5_0000351g0060), *PsaE* (Nitab4.5_0000385g0230), *PsaD* (Nitab4.5_0014875g0010), *PsbQ* (Nitab4.5_0002345g0070), *PsbX* (Nitab4.5_0000073g0060), *OEE1* (Nitab4.5_0000108g0110), *Lhca3* (Nitab4.5_0000923g0200), *Lhcb3* (Nitab4.5_0012832g0010), *Lhcb4* (Nitab4.5_0011597g0020), *Fd* (Nitab4.5_0004129g0010), *F-ATPase delta subunit* (Nitab4.5_0006745g0030), *GAPA* (Nitab4.5_0010299g0040). Error bars indicate \pm SD (n=3). One-way ANOVA with LSD test (*P<0.05, **P<0.01) was used to analyze statistical significance.

Table S1 | Primers used for gene expression analysis and plasmid construction

Primer name	Sequence (5' to 3')	Description
NtCBL5A-1F	ATGGGCTGTGCTTTAAGAAAGCAA	Used for the clone of <i>NtCBL5A</i> CDS
	GA	
NtCBL5A-1R	TCAGAAATCCTTGTAATCTCATC	
NtCBL5A-3F- <i>Sac</i>	<u>CGAGCTCAT</u> GGGCTGTGCTTTAAG	
I	AAAGCAAGA	Used for the construction of plasmid
NtCBL5A-3R- <i>Kpn</i>	GGG <u>G</u> TACCTCAGAAATCCTTGTA	pCHF3- <i>NtCBL5A</i>
I	ATCTCATC	
NtCBL5Apro-1F-	ACGCG <u>TCGAC</u> GTTAGATTGTCCC	
<i>Sal</i> I	TCCGTG	Used for the construction of plasmid
NtCBL5Apro-1R-	TCCCCCGGGTTATAGTAATATTTT	pBI101- <i>NtCBL5Apro::GUS</i>
<i>Sma</i> I	TGTGTTGTTATG	
pCHF3-R	ATTCTGGTGTGTGCGCAATG	For the identification of <i>NtCBL5A</i> - OE transgenic tobacco.
		For the identification of
pBI101-F	CCGATTCATTAATGCAGCTG	<i>NtCBL5Apro::GUS</i> transgenic tobacco.
NtCBL5A-UTR- 31F	TTTGCTAATAAACCCATCTTTG	For the identification of endogenous <i>NtCBL5A</i> , <i>NtCBL5A</i> -UTR-31F was designed based on the 5'-UTR sequence of <i>NtCBL5A</i>
NtCBL5A-81R	TCCAAAGAAAAATGTGTCTGAG	
NtCBL5A-564F	CTCAAGGATATCACAGCTGCATT	For the identification of exogenous <i>NtCBL5A</i> , pCHF3-Allcheck-1 was designed based on the sequence of
pCHF3-Allcheck-1	TGCAGGTCGACTCTAGAGGAT	3'-UTR of exogenous <i>NtCBL5A</i> , referring to pCHF3-Allcheck-2 (Shi et al., 2021).
NRP-qF	ACTATGTTTCCAAAAGGCCTGA	RT-qPCR primers for <i>NRP</i>

Chapter 4

Primer name	Sequence (5' to 3')	Description
NRP-qR	CCATTTAAGCCAAAATCAAGAACC	(Nitab4.5_0000798g0120)
HSR203J-qF	CTTGCGATGCCGGTTTTTCC	RT-qPCR primers for <i>HSR203J</i>
HSR203J-qR	GGCGAGTCGCATTGGAGATA	(Nitab4.5_0002719g0120)
PR1a-qF	GTAATATCCCACTCTTGCCGTG	RT-qPCR primers for <i>PR1a</i>
PR1a-qR	CCTCAGCTAGGTTTTCGCCG	(Nitab4.5_0003771g0010)
PR1b-qF	ACCATTAACCTGGGACAACGG	RT-qPCR primers for <i>PR1b</i>
PR1b-qR	TACGCCAAACCACCTGAGTA	(Nitab4.5_0005400g0020)
PR1c-qF	ATCCCACTCTTGTCATGCTC	RT-qPCR primers for <i>PR1c</i>
PR1c-qR	GAAATCGCCACTTCCCCAAG	(Nitab4.5_0004861g0040)

ABSTRACT

Overexpression of *Nicotiana tabacum* *NtCBL5A* was shown to induce severe necrotic lesions on leaves under salt stress. We hypothesized that overexpression of *NtCBL5A* may interfere with the function of other NtCBLs, possibly through competition of binding to similar NtCIPK partners. In this study, we examined possible *NtCBL/NtCIPK* candidates that overexpressed *NtCBL5A* may interfere with and their role in the salt stress response of tobacco. We assessed the salt tolerance of *NtCBL5A::NtCBL10A* co-overexpressing lines and found that *NtCBL10A* overexpression relieved the necrotic phenotype of *NtCBL5A*-OE lines, indicating *NtCBL10A* may play a role in salt tolerance of tobacco. Further studies showed that *Nt-cbl10a* and *Nt-cbl10b* single mutants exhibited salt sensitivity with reduced chlorophyll content and chlorotic spots on leaves. In addition, *Nt-cbl10acb10b* double mutants showed salt hypersensitivity with fast-developing chlorosis and severe necrotic lesions on leaves under salt stress. Interestingly, the necrosis phenotype of *Nt-cbl10acb10b* double mutants is light-dependent, while the chlorosis phenotype of *Nt-cbl10acb10b* double mutants is light-independent. The stomatal conductance and photochemical efficiency of photosystem 2 (PhiPS2) of the *Nt-cbl10acb10b* double mutant were significantly inhibited at the very early salt stress response stage. NtCIPK24A is a common interactor of NtCBL5A and NtCBL10A, and *Nt-cipk24a* and *Nt-cipk24b* single mutants showed slight salt sensitivity. Results in this study indicate that *NtCBL10* is a key component in the salt tolerance of tobacco, and NtCIPK24A could be one of the partners of NtCBL10 in the salt stress response of tobacco.

Keywords: CBL10, CBL5, CBL4, CIPK24, salt tolerance, tobacco, Na⁺, Cl⁻

INTRODUCTION

The Calcineurin B-like Protein (CBL) - CBL-interacting Protein Kinase (CIPK) network is involved in plant development and stress adaptation as well as in the crosstalk between development and stress adaptation (Mao et al., 2022). In *Arabidopsis thaliana*, several CBL and CIPK components have been reported to be involved in the salt stress response of plants. The most well-known CBL-CIPK pathway that is responsible for salt tolerance is the SOS (salt overly sensitive) pathway: AtCBL4 (AtSOS3) works with AtCIPK24 (AtSOS2) to phosphorylate and activate the PM-localized Na^+/H^+ antiporter AtSOS1, leading to Na^+ extrusion from the plant cells (Qiu et al., 2002; Shi et al., 2002; Nunez-Ramirez et al., 2012).

The SOS pathway was reported to be conserved in many other plant species, including *Brassica napus*, *Malus domestica*, *Oryza sativa*, *Populus trichocarpa*, *Setaria italica*, and *Solanum lycopersicum* (Martinez-Atienza et al., 2007; Tang et al., 2010; Hu et al., 2012; Liu et al., 2015; Zhang et al., 2017; Cho et al., 2021). Recently, the SOS pathway was shown to include additional CBL-CIPK components. AtCBL8 was reported to be a Ca^{2+} -sensor switch for enhanced SOS pathway efficiency (Steinhorst et al., 2022). The AtCBL8-AtCIPK24-AtSOS1 pathway is activated by a higher Ca^{2+} -signal amplitude: the structural conformation, interaction with AtCIPK24, and AtCIPK24-mediated phosphorylation of AtCBL8 are largely Ca^{2+} -dependent. This indicates that the AtCBL8-AtCIPK24 pathway activates SOS1 when enough cytosolic Ca^{2+} is induced by high salt stress. Furthermore, different from *At-cbl4* mutants that are sensitive to a very low degree of salt stress (25 mM NaCl), the *At-cbl8* mutant only exhibits salt sensitivity under a high degree of salt stress (75 mM or 100 mM NaCl) (Mehra and Bennett, 2022; Steinhorst et al., 2022). AtCBL10 is regarded as another addition to the SOS pathway because AtCBL10-AtCIPK8 positively regulates the SOS1 activity of extruding excess Na^+ from shoots of plants subjected to salinity (Yin et al., 2019). In addition, AtCBL10-AtCIPK24 was predicted to activate a tonoplast-localized Na^+/H^+ exchanger AtNHX for Na^+ sequestration into vacuoles in leaves but this has not been evidenced (Kim et al., 2007).

Tobacco (*Nicotiana tabacum*) is considered to be a relatively salt-tolerant crop but the underlying tolerance mechanisms are unknown. A recent report showed that the isolated leaves from *N. benthamiana* plants were able to detoxify Na^+ rapidly even under massive salt loads by compartmentation of cytosolic Na^+ into vacuoles (Graus et al., 2023). Whether *CBL* genes play a regulatory role in salt tolerance of tobacco, for instance in regulating Na^+ transport over the vacuolar membrane similar to *Arabidopsis*, remains to be established. We showed in a previous report that there are 24 *NtCBL* genes in *N. tabacum*, and that overexpression of *NtCBL5A* and *NtCBL4A-1* enhanced the salt sensitivity of transgenic tobacco, leading to similar necrotic lesions on leaves (Chapter 3, Chapter 4) (Mao et al., 2021). Whether these genes indeed play roles in the salt stress response and salt tolerance in wild-type tobacco remains to be established. The ectopic overexpression of a gene, especially for the gene whose expression is normally limited to specific conditions or specific cell types, can interfere with other proteins, complexes, or pathways, for instance by competitive interaction (Prelich, 2012). We hypothesized that the ectopic (over)expression of *NtCBL5A* or *NtCBL4A-1* might compete with other components of the CBL-CIPK network (for instance the CBL10-CIPK pathway) (Mao et al., 2021). To identify potential CBL-CIPK pathways that overexpressed *NtCBL5A* and *NtCBL4A-1* may interfere with, we conducted a yeast-two hybrid assay first to screen the *NtCBL* proteins that share the same *NtCIPK* interactors with *NtCBL5A* and *NtCBL4A-1*. Then we co-overexpressed *NtCBL5A* and the candidate gene *NtCBL10A* and evaluated the salt tolerance of *NtCBL10A::NtCBL5A* co-overexpressing lines as well as loss-of-function mutants of *NtCBL10*. In addition, we also constructed the loss-of-function mutants of *NtCIPK24* and evaluated their salt tolerance because *NtCIPK24A* is the common interactor of *NtCBL4A-1*, *NtCBL5A*, and *NtCBL10A*. In summary, our results demonstrate that *NtCBL10* is a key component in the salt tolerance of tobacco, with likely diverse functions in ion homeostasis that are essential for maintaining photosynthetic capacity. Furthermore, we hypothesize that *NtCIPK24A* could be one of the partners of *NtCBL10* in the salt

stress response of tobacco.

MATERIALS AND METHODS

Plant materials, growth conditions, and application of salt treatment

N. tabacum L. cv. Zhongyan 100 cultivar was used as plant material in this study. For determining the expression profiles of *NtCBL* genes in different tobacco tissues at a young stage, tobacco plants were grown in 2022 at Unifarm, Wageningen University & Research in the Netherlands. The conditions of the greenhouse were 16 h light / 8 h dark at 25/23°C and 70% relative humidity. The shortwave radiation level was maintained in the greenhouse compartment using artificial PAR (photosynthetically active radiation) when the incoming shortwave radiation was below 200 Wm⁻² (Mao et al., 2021). Tobacco seeds were first sown in the soil. At 20 days after germination (DAG), the young tobacco plants were transplanted in rock-wool plugs within float trays for hydroponic cultivation (1/2 Hoagland's nutrient solution). After 6 days of acclimatization (at ~26 DAG), plants were transplanted to a circular flow hydroponic system filled with 1/2 Hoagland's nutrient solution (500 L). The water used to prepare 1/2 Hoagland's nutrient solution contained trace amounts of Na⁺ and Cl⁻ (5.51 µg/ml and 7.88 µg/ml, respectively). After 6 days of acclimatization (at ~ 32 DAG), NaCl was added to the nutrient solution to a concentration of 50 mM on the first day to avoid salt shock, and 100 mM NaCl concentration was reached the next day, and 200 mM NaCl concentration was reached the next day after 100 mM NaCl treatment. From the day of 100 mM NaCl treatment, photographs of the plants were taken and different tissues (leaf blades: all leaves with main veins removed; main veins: main veins from all leaves; stems; roots) of young tobacco plants were sampled every day for ion content measurement until harvest. For assessing salt tolerance, chlorophyll content was measured with the Apogee MC-100 Chlorophyll Meter (Masaló and Oca, 2020), and stomatal conductance and chlorophyll fluorescence were measured with the LI-600 Porometer/Fluorometer (Price, 2021).

Cultivation of grafted and excised plants

For grafting, strong tobacco plants were selected. The stems of the scion and stock plants were cut with grafting scissors and joined by wrapping the wound with preservative film. After one month the wound was healed and the grafted plants were subjected to salt stress. For excised plants, the roots of plants were cut and their stems were planted in rock-wool plugs for 1 week of acclimatization, then salt stress was applied.

Application of dark treatment

For the covering treatment, the 4th leaves of the used plants were covered with aluminum foil at the same time as the initiation of the salt treatment. For the dark treatment, whole plants were covered with light-tight black trays at the same time as the initiation of the salt treatment.

Generation of NtCBL10A-OE plants and NtCIPK24A-OE plants

To generate the gene overexpressing lines, *Agrobacterium* carrying pCHF3-NtCBL10A plasmid and pCHF3-NtCIPK24A plasmid were introduced into cultivar Zhongyan 100 by the *Agrobacterium*-mediated leaf disc transformation method (Horsch et al., 1985). The screening of homozygous transgenic plants was done as previously described (Mao et al., 2021). Primers for cloning genes, identifying positive transgenic plants, and quantifying overexpression levels are listed in Table S2.

Generation of gene-editing mutants

The sgRNAs (Table S2) were designed on the online website CRISPR MultiTargeter <http://www.multicrispr.net/index.html>. The sgRNA fragments were synthesized and inserted at the *Bsa* I site of the pDC45 vector (Li et al., 2022) using T4 ligase (Accurate Biotechnology (Hunan) Co., Ltd, Cat No./ID: AG11801, Changsha, China). To generate the gene-editing lines, pDC45-NtCBL10A, pDC45-NtCBL10B, pDC45-NtCBL10, pDC45-NtCIPK24A, pDC45-NtCIPK24B, and pDC45-NtCIPK24 plasmids were transformed into *Agrobacterium tumefaciens* EHA105 and then were introduced into Zhongyan 100 by the *Agrobacterium*-mediated leaf disc transformation method (Horsch et al., 1985). The edited sequences of *NtCBL10A*

and *NtCBL10B* were identified by PCR with the primer pairs pDC45-NtCBL10A-JCF/pDC45-NtCBL10A-JCR and pDC45-NtCBL10B-JCF/pDC45-NtCBL10B-JCR (Table S2), respectively. The editing of *NtCIPK24A* and *NtCIPK24B* were identified by PCR with the primer pairs pDC45-NtCIPK24A-JCF/pDC45-NtCIPK24A-JCR and pDC45-NtCIPK24B-JCF/pDC45-NtCIPK24B-JCR (Table S2), respectively.

Yeast two-hybrid assay

The coding sequences of *NtCBL1A-1/1A-2/2A/3A/4A-1/5A/6A/9A/10A* were cloned into the pGADT7 vector, then the plasmids were transformed into yeast strain AH109 (Mehla et al., 2015). The coding sequences of *NtCIPK1A-1/2A/4A/6A/7A-2/11A-2/16A/17A/24A/25A/27A/28A* were cloned into the pGBKT7 vector, and then the plasmids were transformed into another yeast strain Y187 (Mehla et al., 2015). AH109 yeast colony containing a pGADT7-NtCBL plasmid and Y187 yeast colony containing a pGBKT7-NtCIPK plasmid were raised in 0.5 mL 2×YPDA medium for mating 24 hrs (30 °C, 50 rpm shaking bed). Then the 2×YPDA medium with mated AH109 and Y187 yeast strains was centrifuged at 6000 rpm for 1 min, the supernatant was discarded and the yeast was washed three times with 1 mL 0.9% NaCl. 100 µL suspension was distributed onto SD/-Leu-Trp and SD/-Leu-Trp-Ade-His medium, then the Petri dishes were incubated at 30 °C for 3-5 days. The yeast colony grew on the SD/-Leu-Trp-Ade-His medium was transferred to new SD/-Leu-Trp-Ade-His medium for further screening (repeat three times).

Statistical analysis

Statistical analysis was done using IBM SPSS Statistics 23 software. Significant differences were examined by Student's *t* test or one-way ANOVA with LSD test at $p < 0.05$ and $p < 0.01$. The figures were drawn by GraphPad Prism 6.0.

RESULTS

The identification of NtCIPK family members and their interactions with NtCBLs

A genome-wide search for NtCIPKs was conducted in the *N. tabacum* genome using

the protein sequences of 26 *A. thaliana* AtCIPKs as queries. Fifty-seven *NtCIPK* genes were identified and numbered according to the names of the most similar *AtCIPK* genes (Figure S1, Table S1). Twenty-nine *NtCIPKs* had the highest sequence similarity with CIPKs of the maternal progenitor *N. sylvestris* and were labeled “A”, while 28 *NtCIPKs* were more similar to CIPKs of the paternal progenitor *N. tomentosiformis* and were labeled “B”. *NtCIPKs* with the highest similarity to the same *AtCIPK* protein were numerically ordered. For example, the three *NtCIPK* genes that were found to be the most similar to *AtCIPK1* were named *NtCIPK1A-1*, *NtCIPK1A-2*, and *NtCIPK1A-3*. For brevity, we refer to all the paralogous genes of one specific *NtCIPK* when “A” or “B” is not specifically pointed out in this paper. The number of amino acids (AA), theoretical isoelectric point (pI), and molecular weight (MW) of the *NtCIPKs* are listed in Table S1. Some *NtCIPK* genes encode splicing variants that are translated into proteins of different lengths. For these, the one encoded longest protein was selected as a representative.

Twelve *NtCIPK* genes (*NtCIPK1A-1/2A/4A/6A/7A-2/11A-2/16A/17A/24A/25A/27A/28A*) were successfully cloned in our lab. To identify *NtCBL* proteins that are able to interact with the *NtCIPK* proteins encoded by these genes, a yeast-two hybrid assay was conducted. The results showed that *NtCBL4A-1* and *NtCBL5A* were able to bind to the same *NtCIPKs*, and so were *NtCBL1A-1* and *NtCBL1A-2*, as well as *NtCBL2A* and *NtCBL3A* (Figure 1). These pairs of *NtCBL* proteins also have similar amino acid sequences (Chapter 3). *NtCBL4A-1* and *NtCBL5A* share putative *NtCIPK* partners with *NtCBL2A/3A/9A/10A* (Figure 1), indicating overexpressed *NtCBL4A-1* and *NtCBL5A* may be able to compete with these proteins for their *NtCIPK* partners when expressed in the same tissues.

Figure 1. The interaction between *NtCBL* proteins and *NtCIPK* proteins. SD/-Leu-Trp indicates the synthetic defined (SD) media lacking tryptophan (Trp) and leucine (Leu). SD/-Ade/-His/-Leu/-Trp indicates SD media lacking tryptophan (Trp), leucine (Leu), histidine (His), and adenine (Ade). Red squares indicate the positive interaction between proteins in the yeast-hybrid system.

The salt sensitivity of *NtCBL5A*-OE is dependent on the shoot genotype

Most *NtCBL* members have expression preference for either shoots or roots: *NtCBL2*, 3, and 10 are mainly expressed in shoots while *NtCBL9* is mainly expressed in roots (Chapter 3). The phenotype of *NtCBL4A-1*-OE and *NtCBL5A*-OE transgenic tobacco plants is mainly manifested in the leaves. To see whether the phenotype is established by interference with *NtCBL*-involving salt stress response mechanisms that originate in the roots or the shoots, we conducted a grafting experiment with WT as root stock and *NtCBL5A*-OE line (OE-2) as the scion, and vice versa. Results showed that the necrotic phenotype was visible in the plants with *NtCBL5A*-OE as the scion, but not with *NtCBL5A*-OE as the stock (Figure 2A and 2B). In addition, we conducted salt stress on excised (rootless) shoots (Figure 2C). The rootless shoots of *NtCBL5A*-OE lines (OE-2 and OE-15) also exhibited the necrosis phenotype under salt stress. These results demonstrate that the salt-induced necrosis of *NtCBL5A*-OE under salt stress is triggered in the shoot. Therefore, *NtCBL5A*

overexpression is more likely to interfere with the function of other *NtCBL* genes such as *NtCBL2*, *NtCBL3*, and *NtCBL10* which are mainly expressed in shoots. (Chapter 3).

Figure 2. Salt treatments on grafted or excised WT and *NtCBL5A*-OE lines under salt stress (100 mM NaCl). Scale bars=10 cm. **(A)** The phenotype of grafted plants under salt stress at 30 DAT (days after reaching 100 mM NaCl treatment). The left grafted plant is *NtCBL5A*-OE-2 as the stock and WT as the scion, and the right grafted plant is WT as the stock and *NtCBL5A*-OE-2 as the scion. **(B)** The phenotype of the grafted plant with *NtCBL5A*-OE-2 as the scion of a lateral branch of WT at 30 DAT. **(C)** The phenotype of excised shoot of WT and *NtCBL5A*-OE lines under salt stress at 7 DAT.

***NtCBL10A* overexpression relieves the salt sensitivity of *NtCBL5A*-OE lines**

Of the three possible candidates involved in the salt-sensitive necrotic phenotype of *NtCBL4A-1*-OE and *NtCBL5A*-OE lines, *NtCBL10* is the most likely candidate.

Arabidopsis AtCBL10 is a well-known component in the salt stress signaling and response pathway that is linked to the SOS pathway (AtCBL4-AtCIPK24 pathway) and it was suggested to regulate Na⁺ sequestration into vacuoles (Kim et al., 2007).

To establish a possible role for *NtCBL10* in the salt stress response of tobacco and the necrotic phenotype of *NtCBL4A-1* and *NtCBL5A*, we crossed the homozygous *NtCBL5A*-OE-2 line with homozygous *NtCBL10A*-OE lines (OE-1, OE-16) and assessed the phenotype of the hybrid lines co-overexpressing *NtCBL5A* and *NtCBL10A* under salt stress. Lines co-overexpressing *NtCBL4A* and *NtCBL5A* were included as well. Co-overexpression of *NtCBL4A-1* and *NtCBL5A* had an additive effect on the salt sensitivity of transgenic tobacco with fast-developing necrosis (Figure 3A), while *NtCBL10A* overexpression greatly relieved the necrotic symptoms of *NtCBL5A*-OE lines (Figure 3A) and improved growth vigor under saline conditions (Figure 3C and 3D). These results are in line with the hypothesis that ectopic (over)expression of *NtCBL5A* interferes with the function of *NtCBL10A* in salt tolerance.

Figure 3. The shoot phenotype of hybrid lines (*WT*×*NtCBL5A-OE*, *NtCBL4A-1-OE*×*NtCBL5A-OE*, *NtCBL10A-OE-16*×*NtCBL5A-OE*, *NtCBL10A-OE-1*×*NtCBL5A-OE*) under control conditions and salt stress (100 mM NaCl). Scale bars=10 cm. **(A)** The shoot phenotype of hybrid lines at 9 DAT (days after reaching 100 mM NaCl treatment). White arrowheads indicate the leaves which were zoomed in at the bottom part of the panel. **(B)** Relative expression analysis of exogenous *NtCBL5A*, *NtCBL4A-1*, and *NtCBL10A* in leaves of different hybrid lines determined by RT-qPCR. Error bars indicate ±SD (n=3). The expression levels are relative to the reference gene *NtL25* (Schmidt and Delaney, 2010). **(C and D)** The shoot fresh weight and plant height of hybrid lines at 9 DAT. Error bars indicate ±SD (n=8). Different letters above bars (a, b, and c) indicate significant statistical differences based on one-way ANOVA with LSD test ($P<0.05$).

Growth response to salt stress of *NtCBL10* loss-of-function mutants

Being an allotetraploid, tobacco has two copies of *AtCBL10* orthologs: *NtCBL10A* and *NtCBL10B* originating from the maternal diploid tobacco species *N. sylvestris* and paternal diploid tobacco species *N. tomentosiformis*, respectively (Chapter 3). *NtCBL10A* has a higher overall expression level (about 3 fold) than *NtCBL10B* in all detected tissues (Chapter 3) and both their expression levels were upregulated in the leaf blade by 100 mM NaCl stress. Their protein sequences differ only at three amino acids (Figure S2), indicating they may have functional redundancy. To gain further insight into the role of *NtCBL10* in salt tolerance of tobacco and the interference of *NtCBL4A-1* and *NtCBL5A* overexpression with this role, we constructed the single mutants *Nt-cbl10a* (Figure S3A) and *Nt-cbl10b* (Figure S3B) as well as the double mutant *Nt-cbl10acb10b* (Figure S3C) using the CRISPR/Cas9 technique. All of the gene editing-induced mutations cause premature termination of protein translation (Figure S3).

The salt tolerance of the knock-out mutants was assessed under 100 mM NaCl treatment. At 7 DAT (days after reaching 100 mM NaCl treatment), the phenotype and growth characteristics of the mutants were similar to WT plants under control conditions (Figure 4). Under salt stress, however, the *Nt-cbl10a* and *Nt-cbl10b* single mutants exhibited chlorotic spots on their leaves, and the *Nt-cbl10acb10b* double

mutant even showed extremely fast-developing severe chlorosis with necrotic lesions (Figure 4A, Figure S4). In addition, the growth vigor of *Nt-cbl10acb10b* double mutant was significantly reduced under salt stress compared to WT plants (Figure 4B-E). These results clearly indicate that *NtCBL10A* and *NtCBL10B* play a key role in the salt tolerance of tobacco and they may be functionally redundant. The *Nt-cbl10a* single mutants exhibited earlier and more severe salt-sensitive phenotype than *Nt-cbl10b* single mutant (Figure S4), which is consistent with the higher expression level of *NtCBL10A* compared to *NtCBL10B* (Chapter 3).

Figure 4. The shoot phenotype of WT, *Nt-cbl10a* single mutant, *Nt-cbl10b* single mutant, *Nt-cbl10acb10b* double mutant, and *NtCBL10A*-OE lines under control conditions and salt stress (100 mM NaCl). Scale bars=10 cm. **(A)** The shoot phenotype of plants at 8 DAT. White arrowheads indicate the 4th leaves which were zoomed in at the bottom part of the panel. **(B-E)** The plant height,

shoot fresh weight, 4th leaf width, and 4th leaf length of all lines at 8 DAT (days after reaching 100 mM NaCl treatment). Error bars indicate \pm SD (n=6). Asterisks indicate statistically significant differences compared with WT (#) under control or saline conditions (Student's *t* test, **p*<0.05 and ***p*<0.01).

Physiological response to salt stress of *NtCBL10* loss-of-function mutants

For the physiological characterization of the salt response of the *NtCBL10* loss-of-function mutants, we measured the chlorophyll content, stomatal conductance, and photochemical efficiency of photosystem 2 (PhiPS2) at 3 DAT and 7 DAT. The chlorophyll content of the *Nt-cbl10acb10b* double mutant was already greatly reduced under salt stress at 3 DAT (Figure 5A). At 7 DAT, the chlorophyll contents of *Nt-cbl10a* and *Nt-cbl10b* single mutants were also significantly reduced by salt stress but much less than that of *Nt-cbl10acb10b* double mutant (Figure 5D). Similarly, stomatal conductance and chlorophyll fluorescence of *Nt-cbl10acb10b* double mutant were also decreased already at 3 DAT (Figure 5B and 5C). The PhiPS2 of *Nt-cbl10a* and *Nt-cbl10b* single mutants was not significantly reduced at both 3 DAT and 7 DAT compared to WT (Figure 5C and 5F), indicating that the loss of single *NtCBL10A* or *NtCBL10B* did not severely affect the photosynthesis of tobacco.

The leaf ion contents of all lines were measured to assess whether changed ion homeostasis would underly the extreme salt sensitivity of the *NtCBL10* loss-of-function mutants. Results showed that Na⁺, Ca²⁺, and Mg²⁺ contents were not significantly different between WT, mutants, and *NtCBL10A*-OE lines under both control and saline conditions (Figure 5G, S5A, and S5B). Interestingly, the Cl⁻ content of the *Nt-cbl10acb10b* double mutant was significantly lower than that of WT and other mutants under salt stress (Figure 5H), while the K⁺ content was increased in the double mutant (Figure 5I).

Figure 5. The determination of physiological parameters of WT, *Nt-cbl10a*, *Nt-cbl10b* single mutants, *Nt-cbl10acb10b* double mutant, and *NtCBL10A*-OE lines under control conditions and salt stress (100 mM NaCl). (A-F) The chlorophyll content, stomatal conductance, and chlorophyll fluorescence of all lines at 3 DAT (days after reaching 100 mM NaCl treatment) (A-C) and 7 DAT (D-F). Error bars indicate \pm SD (n=6). (G-I) Ion contents (Na⁺, Cl⁻, and K⁺) in leaf blades of all lines under control and saline conditions at 7 DAT. Error bars indicate \pm SD (n=4). Asterisks indicate statistically significant differences compared with WT (#) under control or saline conditions (Student's *t* test, **p*<0.05 and *p*<0.01).**

Our results showed that in the *Nt-cbl10acb10b* double mutant, photosynthetic activity is inhibited and chlorophyll breakdown is initiated very shortly after imposing salt stress. We examined this fast-developing phenotypic response of the double mutant in more detail, monitoring changes in photosynthetic parameters and ion contents in the *Nt-cbl10acb10b* double mutant and WT tobacco plants every day after imposing 100 mM NaCl stress (0-5 DAT). The chlorophyll content, stomata conductance, and photochemical efficiency of photosystem 2 (PhiPS2) of *Nt-cbl10acb10b* double mutant were affected already at 1 DAT (48 hrs after the first 50

mM NaCl addition at 0 DAT, 24 hrs after reaching 100 mM NaCl) (Figure 6B-D) with chlorotic symptoms visible already at 1 DAT and necrotic spots visible at 2 DAT (Figure 6A), and further developing chlorosis and necrosis over the next few days. At these very early stages of salt treatment, Na⁺ contents were only slightly increased in all plants, and Na⁺ content of the *Nt-cbl10acb10b* double mutant accumulated at a similar rate as WT from 0 to 5 DAT (Figure 6E). These results do not support a role for leaf Na⁺ accumulation and toxicity in the severe salt sensitivity phenotype of the *Nt-cbl10acb10b* double mutant. Ca²⁺ and Mg²⁺ contents were not significantly different between WT and mutants under both control and saline conditions (Figure S5C and S5D). In addition, the Na⁺/K⁺ ratios of WT and *Nt-cbl10acb10b* double mutant under salt stress were also quite similar (Figure S5E), indicating the salt-sensitive phenotype of the double mutant is not likely because of the imbalanced Na⁺/K⁺ ratio. Interestingly, Cl⁻ accumulated at a significantly lower rate in the *Nt-cbl10acb10b* double mutant compared to WT (Figure 6F), and the Na⁺/Cl⁻ accumulation ratio in the double mutant was much higher than that in the WT (Figure S5F).

Figure 6. The phenotype and physiological parameters of WT and *Nt-cbl10acb10b* double mutant on different time points after salt treatment (100 mM NaCl). (A) The shoot phenotype of plants at 0-5 DAT (days after reaching 100 mM NaCl treatment). **(B-D)** The chlorophyll content, stomatal conductance, and chlorophyll fluorescence of all lines at 0-5 DAT. Error bars indicate $\pm\text{SD}$ ($n=12$). **(E-G)** Ion contents (Na^+ , Cl^- , and K^+) in leaf blades of all lines under control and saline conditions at 0-5 DAT. Error bars indicate $\pm\text{SD}$ ($n=4$). Asterisks indicate statistically significant differences of *Nt-cbl10acb10b* double

mutant compared with WT under control or saline conditions at different time points (Student's *t* test, **p*<0.05 and ***p*<0.01).

The chlorosis and necrosis phenotypes of *Nt-cbl10acb10b* double mutant under salt stress are independent

Previous reports have shown that some lesion-mimic phenotype is connected to light or defective photosystems (Zulfugarov et al., 2014; Bruggeman et al., 2015; Wang et al., 2015; Tang et al., 2020). In the *Nt-cbl10acb10b* double mutant, photosynthesis was affected already at a very early stage of salt treatment (Figure 5C and 6D). We explored whether the salt-sensitive phenotype of the *Nt-cbl10acb10b* double mutant leaves was light-dependent in a dark treatment (whole plants in the dark at the same time with salt treatment). Results showed that the *Nt-cbl10acb10b* double mutant leaves still suffered possibly even more from early chlorophyll breakdown and chlorosis of the leaf blades in the dark, but necrotic lesions were no longer visible (Figure 7B). These results suggest that the salt stress-induced necrosis of the *Nt-cbl10acb10b* double mutant leaves is dependent on light but the breakdown of chlorophyll is light-independent.

Ion content results showed that Na⁺ accumulation of both WT and *Nt-cbl10acb10b* double mutants was very low from 1 DAT to 6 DAT (Figure 7D), which may argue against a role for Na⁺ accumulation in the chlorophyll breakdown of the *Nt-cbl10acb10b* double mutant. Interestingly, the reduced rate of Cl⁻ accumulation in the *Nt-cbl10acb10b* double mutant compared to WT under salt stress was reversed in the leaves grown in the dark (Figure 6F and 7E). Ca²⁺ and Mg²⁺ contents were still not significantly different between WT and mutants under both control and saline conditions in the dark (Figure S5G and S5H).

Figure 7. The phenotype and physiological parameters of WT and *Nt-cbl10acb10b* double mutant on different time points after salt treatment (100 mM NaCl) in the dark. **(A)** The shoot phenotype of plants at 7 DAT (days after reaching 100 mM NaCl treatment). **(B)** The shoot phenotype of plants at 0-7 DAT. Scale bar=10 cm. **(C)** The chlorophyll content of all lines at 0-7 DAT. Error bars indicate \pm SD (n=8). **(D-F)** Ion contents (Na⁺, Cl⁻, and K⁺) in leaf blades of all lines under control and saline conditions at 1, 3, and 6 DAT. Error bars indicate \pm SD (n=3). Asterisks indicate statistically significant differences of *Nt-cbl10acb10b* double mutant compared with WT under control or saline conditions at different time points (Student's *t* test, **p*<0.05 and ***p*<0.01).

***NtCIPK24* loss-of-function mutants exhibited slight salt sensitivity under high salt stress**

A suggested CBL10-interacting partner in the vacuole-targeted salt stress response is CIPK24 (Kim et al., 2007). To study the role of *NtCIPK* in the salt stress response of tobacco, we constructed the single mutants *Nt-cipk24a* and *Nt-cipk24b* (Figure S6A and S6B), and also tried to construct the double mutant *Nt-cipk24acipk24b* (Figure S6C). However, the double knockout of both *NtCIPK24A* and *NtCIPK24B* failed because of defective callus development (Figure S6D), indicating that *NtCIPK24* may have a key function in plant development.

5

The salt tolerance of *Nt-cipk24a* and *Nt-cipk24b* single mutants was assessed under 100 mM NaCl and 200 mM NaCl treatments. Under control conditions, the *Nt-cipk24b-7* mutant had an inferior growth vigor compared to WT, all of the other lines showed similar growth vigor as the WT under control. Under 100 mM NaCl treatment, the growth vigor of *Nt-cipk24a* and *Nt-cipk24b* single mutants was slightly inhibited (Figure 8). The growth vigor inhibition of *Nt-cipk24a* and *Nt-cipk24b* single mutants was more obvious under 200 mM NaCl treatment (Figure 8). In addition, the *Nt-cipk24a* and *Nt-cipk24b* single mutants had a minor salt-sensitive phenotype with chlorosis spots on the leaves under 200 mM NaCl (Figure 8A and 8E). The *Nt-cipk24b* single mutant was a bit more sensitive to salt stress than the *Nt-cipk24a* single mutant (Figure 8), which is consistent with *NtCIPK24B* having a slightly higher expression level than that of *NtCIPK24A* (analysis from published RNA-seq data, Figure S7). However, we did not find a significant difference in stomatal conductance, chlorophyll fluorescence, and ion contents between WT and *Nt-cipk24* single mutants under 200 mM NaCl (Figure S8). This may be because of functional redundancy between *NtCIPK24A* and *NtCIPK24B* in the salt stress response of tobacco.

Figure 8. The shoot phenotype and physiological parameters of wild-type (WT), *Nt-cipk24a* single mutant, *Nt-cipk24b* single mutant, and *NtCIPK24A*-overexpressing (OE) line (OE-5) under control conditions and salt stress (100 mM and 200 mM NaCl). Scale bars=10 cm. **(A)** The shoot phenotype of WT, *Nt-cipk24a* single mutant, *Nt-cipk24b* single mutant, and *NtCIPK24A*-OE line at 13 DAT (days after reaching 100 mM NaCl treatment). White arrowheads indicate the 4th leaves which were zoomed in at the bottom part of the panel. **(B-E)** The shoot fresh weight, 4th leaf length, 4th leaf width, and chlorophyll content of all lines. Error bars indicate \pm SD (n=6). Asterisks indicate statistically significant differences compared with WT (#) under control or saline conditions (Student's *t* test, **p*<0.05 and ***p*<0.01).

DISCUSSION

Members of the *CBL* gene family play important roles in stress response of plants, and very often are involved in the regulation of ion homeostasis (Mao et al., 2022). The severe salt stress-sensitive necrotic phenotype of tobacco plants ectopically overexpressing *NtCBL4A-1* and *NtCBL5A* led us to propose that *NtCBL4A-1* and *NtCBL5A* might affect essential salt stress signaling pathways and the salt stress response, possibly by interfering with the function of other CBL family members (Chapter 3 and 4). In this study, we demonstrate that *NtCBL10* is a potential candidate that can bind the same CIPK partner (*NtCIPK24A*) as *NtCBL4A-1* and *NtCBL5A*. Knocking out *NtCBL10* in tobacco results in an even more severe salt-sensitive phenotype that includes very fast-developing chlorosis in addition to necrotic symptoms. The early breakdown of chlorophyll along with fast-reduced PhiPS2 suggests a direct devastating effect on photosynthetic components in the *Nt-cbl10acb10b* double mutant. Our results show that *NtCBL10* is of pivotal importance to the salt tolerance of tobacco, and that *NtCBL10* may be involved in the regulation of several essential salt stress response pathways.

In this study, the *Nt-cbl10acb10b* double mutant exhibited a phenotype with both chlorosis and necrosis under salt stress in the light, while it only exhibited the chlorosis symptom under salt stress in the dark. These results indicate that the chlorosis phenotype is light-independent and the necrosis phenotype is light-dependent, and these two kinds of phenotype may be caused by different disturbed pathways because of the loss of *NtCBL10*. A possible explanation for this may be linked to the wide range of regulatory functions that *CBL10* appears to have in response to salt stress. In *Arabidopsis*, *AtCBL10* was found to regulate not only Na^+ transport, but also H^+ , K^+ , and Ca^{2+} transport through both CIPK-dependent and CIPK-independent pathways (Plasencia et al., 2020).

The light-dependent necrotic phenotype of *Nt-cbl10acb10b* and Na^+ homeostasis as well as Cl^- homeostasis

A dark treatment was conducted on *NtCBL5A*-OE lines as well, and the results

showed that their necrotic phenotype is also light-dependent (Figure 9), which is similar to the necrosis observed in the *Nt-cbl10acb10b* double mutant. However, the light-independent fast-developing chlorosis phenotype appears to be unique to the *Nt-cbl10acb10b* double mutant. These results indicate that the ectopic overexpression of *NtCBL5A* may only interfere with the *NtCBL10* activities that protect against necrosis under saline conditions.

A role for CBL10 together with CIPK24 in regulating Na^+ transport over the tonoplast was proposed in *Arabidopsis* (Kim et al., 2007). It was suggested that the tonoplast-localized CBL10-CIPK24 complex regulates Na^+ sequestration into the vacuole through the vacuolar NHX transporter, which was initially thought to be a Na^+/H^+ antiporter (Kim et al., 2007). However, there is some controversy regarding the function of the vacuolar NHX transport activity, and other Na^+ transporters may be involved (Plasencia et al., 2020).

The fact that tonoplast-targeted regulation of Na^+ transport by CBL10 under saline conditions requires association with CIPK24 may explain why overexpression of *NtCBL4A-1* and *NtCBL5A* resulted in necrosis but not extensive chlorosis as observed in the *Nt-cbl10acb10* double mutant: when ectopically expressed, *NtCBL4A-1* and *NtCBL5A* may compete with *NtCBL10* for *NtCIPK24* binding, thus negatively affecting the CBL10-CIPK24-regulated Na^+ sequestration in the vacuole specifically. This hypothesis is supported by two observations: (1) the *NtCBL4A-1*-OE::*NtCBL5A*-OE hybrid plants had more severe salt sensitivity than WT::*NtCBL5A*-OE hybrid plants, indicating *NtCBL4A-1* overexpression may interfere with the same component as *NtCBL5A* overexpression. (2) *NtCBL10A* overexpression was able to partly reverse the salt-sensitive phenotype caused by overexpression of *NtCBL5A* in a *NtCBL10A*-OE::*NtCBL5A*-OE hybrid plant with more moderate salt sensitivity than WT::*NtCBL5A*-OE hybrid plants.

The initial increase in whole leaf Na^+ content of the *Nt-cbl10acb10b* double mutant was shown to be quite similar to that of WT plants (Figure 6E). However, WT plants can store excess Na^+ in the vacuole. If Na^+ is not transported to the vacuole in the

Nt-cbl10acb10b double mutant, Na^+ will accumulate to toxic levels in the cytosol much faster, and this can cause necrotic symptoms. In recent years, it has become evident that CBL10 also affects Na^+ transport over the plasma membrane as part of the SOS pathway (Plasencia et al., 2021). AtCBL10-AtCIPK8 and AtCBL10-AtCIPK24 modules appear to be able to interact with SOS1 activity of extruding Na^+ into the apoplast (Quan et al., 2007; Lin et al., 2009; Yin et al., 2019). In the *Nt-cbl10acb10b* double mutant, the loss of this Na^+ extruding activity would also contribute to a higher relative Na^+ concentration in the cytosol. The lack of necrotic symptoms under a dark treatment may then be explained by the significantly lower leaf Na^+ accumulation rate of leaves in the dark (Figure 7D).

The *Nt-cbl10acb10b* double mutant also accumulated significantly less Cl^- under salt stress compared to WT (Figure 5H and 6F), indicating that *NtCBL10* is also involved in Cl^- homeostasis. To our knowledge, there is no report about the role of *CBL10* in Cl^- homeostasis regulation. Geilfus (2018) suggested that the disturbance of chloroplastidial Cl^- homeostasis might affect the generation of the pH gradient between the lumen and stroma under Cl^- salinity via an unbalancing of the proton-counterbalancing fluxes of Cl^- , which would lead to the reduction of PS II, but this has not been experimentally confirmed. In the dark treatment, the reduced rate of Cl^- accumulation in the *Nt-cbl10acb10b* double mutant compared to WT under salt stress was reversed (Figure 7E), which is also consistent with the disappearance of the necrotic phenotype in the dark. But whether the difference in Cl^- handling is functionally related to the necrotic symptoms remains to be established.

Figure 9. Shoot phenotype of wild-type (WT) and *NtCBL5A*-overexpressing lines (OE-2 and OE-15) under salt stress (100 mM NaCl) in the dark treatment. Scale bars=10 cm. **(A)** The phenotype of WT and *NtCBL5A*-OE lines under salt stress (S) at 9 DAT (days after reaching 100 mM NaCl treatment). **(B)** The phenotype of WT and *NtCBL5A*-OE lines under salt stress at 12 DAT. White arrowheads indicate the 4th leaves under light (Light), covered by aluminum-foil paper (Covered), and under dark (Dark), which were zoomed in at the right part of the panel.

The light-independent chlorotic phenotype of *Nt-cbl10acb10b* double mutant and other regulatory functions of *CBL10*

The chlorotic symptoms in the *Nt-cbl10acb10b* double mutant developed much

faster than in the *NtCBL4A-1* and *NtCBL5A*-overexpressing lines. Moreover, the chlorotic symptoms of the *Nt-cbl10acb10b* double mutant were observed both under light and dark conditions, while the necrosis was no longer visible under dark conditions. This indicates that the fast-developing chlorosis of the *Nt-cbl10acb10b* double mutant under salt stress may be linked to another impaired function of *NtCBL10* than the one linked to necrosis.

The chlorotic symptoms in the *Nt-cbl10acb10b* double mutant were already detected within 24 hrs of reaching the final NaCl concentration of 100mM NaCl (Figure 6A and 7A). Both chlorophyll content and photochemical efficiency of photosystem 2 (PhiPS2) were also decreased by this time, and decreased further in the next few days (Figure 6B and 6D). This suggests that chlorophyll and possibly other components of the photosynthetic machinery were directly affected by the saline conditions in the *Nt-cbl10acb10b* double mutant, and that *NtCBL10* may play an essential role in protecting chlorophyll and photosynthetic capacity already at very early stages of salt stress.

Although we cannot rule out a role for cytosolic Na⁺ accumulation in the development of the chlorotic symptoms, the low rate of leaf Na⁺ concentration increase in the *Nt-cbl10acb10b* double mutant grown in the dark while chlorotic symptoms still developed very fast suggests that Na⁺ accumulation itself is not causal to the chlorosis and fast breakdown of chlorophyll. As mentioned before, *CBL10* was shown to be involved in the regulation of the transport and distribution of several ions under salt stress, including not only Na⁺ but also H⁺, K⁺, and Ca²⁺ (Plasencia et al., 2020). This leads to the possibility that the effect of the *Nt-cbl10acb10b* double mutant on photosynthetic components and parameters is linked to other regulatory functions of *CBL10*.

Other targets for CBL10 regulation of the salt stress response may be the H⁺ transporters in the tonoplast. In a tomato *Sl-cbl10* mutant, the gene expression of the vacuolar H⁺ pumps *SlAVP1* and *SlVHA-A1* was downregulated under saline conditions (Egea et al., 2018). These are thought to provide the proton gradient over

the tonoplast that drives the Na^+ transport into the vacuole. In addition, AtCBL10 was suggested to regulate plasma membrane H^+ -ATPase activity in *Arabidopsis thaliana* in a CIPK-independent manner, directly interacting with plasma membrane H^+ -ATPases AtAHA4 and AtAHA11 (Xie et al., 2022). Proton pumps in the tonoplast and plasma membrane need to be tuned and are under strict regulation to ensure a balanced pH in the cytosol, which may also involve the NHX family of antiporters (Cosse and Seidel, 2021). Impaired regulation of the H^+ pumps may result in impaired H^+ homeostasis and pH regulation, which can be highly damaging to the leaf cell functioning, and induce chlorophyll breakdown (Long et al., 2017). Whether impaired pH regulation is causal to the fast-developing chlorosis in the *Nt-cbl10acb10b* double mutant under salt stress remains to be established.

CBL10 also functions as a repressor by directly interacting with targets in a CIPK-independent way. AtCBL10 was reported to competitively interact with AKT1 against the AtCBL1/9-AtCIPK23 complex, repressing the potassium uptake regulated by AtCBL1/9-AtCIPK23 (Ren et al., 2013). Our results also showed the K^+ accumulation in *Nt-cbl10acb10b* double mutant was affected under salt stress compared to WT (Figure 5I and 6G). At the very early stage of salt treatment (0-3 DAT), the K^+ accumulation in the double mutant is significantly lower than that in WT but the difference is decreasing with time (Figure 6G). At 5 DAT and 7 DAT, our data showed a higher K^+ accumulation in *Nt-cbl10acb10b* double mutant than that in WT (Figure 5I and 6G). The Na^+/K^+ ratios in WT and *Nt-cbl10acb10b* are always similar during 0-5 DAT (Figure S5E). These results showed that the K^+ homeostasis affected by the loss of *NtCBL10* is changing with time and is complicated, which may rather be a consequence than a cause of salt sensitivity.

Interestingly, CBL10 was also found to directly interact with and repress TOC34 protein, a member of the TOC (translocon of the outer membrane of the chloroplasts) complex with GTPase activity to regulate protein importation into chloroplasts (Cho et al., 2016). The interaction between CBL10 and chloroplast-localized protein seems also linked to the chlorophyll breakdown and PS II defect in *NtCBL10* loss-of-function mutants but needs more research to provide the evidence.

Supplementary Material

Figure S1. Phylogenetic tree of the NtCIPKs and AtCIPKs. The amino acid sequences of AtCIPKs were downloaded from TAIR (<https://www.arabidopsis.org/>). The phylogenetic tree was constructed by MEGA6 using the Neighbor-Joining method.

Figure S2. The protein sequence alignment of NtCBL10A and NtCBL10B.

Figure S3. The position of gRNA, edited sequence, and protein translation of the edited sequence of *Nt-cbl10a* single mutant (A), *Nt-cbl10b* single mutant (B), and *Nt-cbl10acb10b* double mutant (C).

Figure S4. The phenotype of WT and *Nt-cbl10acb10b* double mutants under salt stress on different days after treatment (DAT).

Figure S5. Ca^{2+} and Mg^{2+} contents in leaf blades of plants under control conditions and salt stress (100 mM NaCl). (A and B) Ca^{2+} and Mg^{2+} contents of WT, *Nt-cbl10a*, *Nt-cbl10b* single mutants, *Nt-cbl10acb10b* double mutant, and *NtCBL10A*-OE lines under control conditions and salt stress (100 mM NaCl) at 7 DAT (days after reaching 100 mM NaCl treatment). Error bars indicate $\pm\text{SD}$ (n=4). (C and D) Ca^{2+} and Mg^{2+} contents in leaf blades of WT and *Nt-cbl10acb10b* double mutant under control and saline conditions at 0-5 DAT. Error bars indicate $\pm\text{SD}$ (n=4). (E and F) Na^+/K^+ ratio (mol/mol) and Na^+/Cl^- ratio (mol/mol) in WT and *Nt-cbl10acb10b* double mutant under salt stress at 0-5 DAT. (G and H) Ca^{2+} and Mg^{2+} contents in leaf blades of WT and *Nt-cbl10acb10b* double mutant under control and saline conditions at 1, 3, and 6 DAT in the dark. Error bars indicate $\pm\text{SD}$ (n=3). Asterisks indicate statistically significant differences compared with WT (#) under control or saline conditions (Student's *t* test, * $p<0.05$ and ** $p<0.01$).

Figure S6. The editing way and tissue culture of *Nt-cipk24* mutants. The sgRNA position, edited sequence, and protein translation of the edited sequence of *Nt-cipk24a-40* mutant (A), *Nt-cipk24b-3/7* mutants (B), and *Nt-cipk24acipk24b* double mutant (C). (D) The callus vigor with different sgRNA in tissue culture.

Figure S8. Physiological parameters of wild-type (WT), *Nt-cipk24a* single mutant, *Nt-cipk24b* single mutant, and *NtCIPK24A*-overexpressing (OE) line (OE-5) under control conditions and salt stress (200 mM NaCl) at 8 DAT and the detection of *NtCIPK24A* expression level in WT and *NtCIPK24AOE-5* leaves. (A and B) The stomatal conductance and chlorophyll fluorescence of all lines at 13 DAT (days after reaching 100 mM NaCl treatment). Error bars indicate ±SD (n=6). **(C-G)** The ion contents (Na⁺, Cl⁻, K⁺, Ca²⁺, and Mg²⁺) in leaves of all lines at 13 DAT. Error bars indicate ±SD (n=4). **(H)** The expression level of *NtCIPK24A* (endogenous and exogenous) in WT and *NtCIPK24AOE-5* plant leaves determined by RT-qPCR. Error bars indicate ±SD (n=3). The expression levels are relative to the reference gene *NtL25* (Schmidt and Delaney, 2010). Asterisks indicate statistically significant differences compared with WT (#) under control or saline conditions (Student's *t* test, **p*<0.05 and ***p*<0.01).

AA, the number of amino acids; pI, theoretical isoelectric point; MW, molecular weights. The AA, pI, and MW were calculated with the ExPASy tool (<https://web.expasy.org/protparam/>).

Table S2 | Primer and sgRNA sequences

Primer name	Sequence (5' to 3')	Description
NtCBL10A-1F	ATGGATTCAACCCGAGATTCTC	For the amplification of <i>NtCBL10A</i>
NtCBL10A-1R	TCACAACAAATGGCTTTTCTCCG	
NtCIPK24A-1F	ATGAAGAAAGTGAAGAGGAAG	For the amplification of <i>NtCIPK24A</i>
NtCIPK24A-1R	TCAGCGAGTCATTGTTCTAAG	
pCHF3-R	ATTCTGGTGTGTGCGCAATG	For the identification of <i>NtCBL10A</i> -OE and <i>NtCIPK24A</i> -OE transgenic tobacco together with <i>NtCBL10A</i> -1F and <i>NtCIPK24A</i> -1F, respectively.
pCHF3-Allcheck-2	GATGATACGAACGAAAGCTCTGC	pCHF3-Allcheck-2 (Shi et al., 2021) was designed based on the sequence of 3'-UTR of exogenously overexpressed genes
NtCBL5A-564F	CTCAAGGATATCACAGCTGCATT	For detecting the expression level of exogenous <i>NtCBL5A</i> together with pCHF3-Allcheck-2
NtCBL4A-1-qF	AGTTCTTTCAGATGATGTTGTCG	For detecting the expression level of exogenous <i>NtCBL4A-1</i> together with pCHF3-Allcheck-2

Primer name	Sequence (5' to 3')	Description
NtCBL10A-qF	ACTGGGTTCATTGAGCGAGA	For detecting the expression level of exogenous <i>NtCBL10A</i> together with pCHF3-Allcheck-2
NtCIPK24A-qF	ACAAAATACCGAGACGGGGG	For the detection of <i>NtCIPK24A</i> expression (both endogenous and exogenous) level in the <i>NtCIPK24A</i> -OE plants
NtCIPK24A-qR	AAAACCTCGTGAAGCCGAAC	
NtL25-qF	CAAAAGTTACATTCCACCG	Primers of reference gene <i>NtL25</i> (Schmidt and Delaney, 2010) for RT-qPCR
NtL25-qR	TTTCTTCGTCCCATCAGGC	
NtCBL10A-sgRNA	GTTGGCAAGACGGGCAAGGT	The gRNA sequence for knocking out of <i>NtCBL10A</i>
NtCBL10B-sgRNA	GAAGTTGGGTTATGATTATA	The gRNA sequence for knocking out of <i>NtCBL10B</i>
NtCBL10-sgRNA	CGTCCCAACAAGAAGAAGTT	The gRNA sequence for knocking out of <i>NtCBL10</i>
NtCIPK24A-sgRNA	GTTTGCACAAAATACCGAGA	The gRNA sequence for knocking out of <i>NtCIPK24A</i>
NtCIPK24B-sgRNA	GAATATCTGAGGATGAAGCG	The gRNA sequence for knocking out of <i>NtCIPK24B</i>
NtCIPK24-sgRNA	TCGTGAAGCCGAAGTATGCA	The gRNA sequence for knocking out of <i>NtCIPK24</i>
pDC45-NtCBL10A-JCF	CCTTTCTCTCTCTCTCTGAATT AT	For the identification of edited gene sequence of <i>NtCBL10A</i> in <i>Nt-cbl10a</i> mutants and <i>Nt-cbl10acb10b</i> mutants
pDC45-NtCBL10A-JCR	GATTTCTTCAGAGTTCGAGTTC	
pDC45-NtCBL10B-JCF	ACCACATAAAAAACACACACCTT	For the identification of edited gene sequence of <i>NtCBL10B</i> in <i>Nt-cbl10b</i> mutants and <i>Nt-cbl10acb10b</i> mutants
pDC45-NtCBL10B-JCR	AACAAAAGCAAAGGAAAAAAGG	

Primer name	Sequence (5' to 3')	Description
pDC45- NtCIPK24A-JCF	AATTTTGCCAGCTGTAATGTC	For the identification of edited gene sequence of <i>NtCIPK24A</i> in <i>Nt-cipk24a</i> mutants
pDC45- NtCIPK24A-JCR	CGAAAGGAAGTATATTTTAGTACC TG	
pDC45- NtCIPK24B-JCF	CCTTCTAGTAAGTAAAAAATTCCA TC	For the identification of edited gene sequence of <i>NtCIPK24B</i> in <i>Nt-cipk24b</i> mutants
pDC45- NtCIPK24B-JCR	CAGTTAAATGCTTAGGATAGATAA TTC	

Chapter 6

General Discussion

CBL and CIPK family genes form a complex CBL-CIPK regulatory network that plays vital roles in both plant development and stress responses (Mao et al., 2022). The CBL-CIPK regulatory network is involved in two levels of crosstalk between plant development and stress adaptation: direct crosstalk through interaction with regulatory proteins, and indirect crosstalk through adaptation of correlated physiological processes that affect both plant development and stress responses (Chapter 2) (Mao et al., 2022). The roles of the CBL-CIPK regulatory network are best identified in the model plant *Arabidopsis thaliana* but much less is known in solanaceous crops.

The aim of this thesis was to identify key *CBL* genes in the salt stress response of tobacco. We first conducted a genome-wide analysis of the *NtCBL* gene family (Chapter 3). Twenty-four *NtCBL* genes were identified from *N. tabacum*, from which 14 *NtCBL* genes were derived from the maternal genome donor *N. sylvestris* and 10 were derived from the paternal genome donor *N. tomentosiformis*. These *NtCBL*s were clustered into three different groups based on phylogenetic analysis, and these groups have distinct N-terminal characteristics. The EF-hand motifs of *NtCBL*s contain amino acid substitutions and configuration changes that may be responsible for the variation in Ca^{2+} -binding abilities. Most *NtCBL* genes have splicing variants. The 5'-UTRs of homoeologous *NtCBL* genes from the parental genomes of allotetraploid tobacco differ in length and intron presence, which may contribute to variations in gene translation efficiency or preferences of protein interaction. The expression profile of *NtCBL* genes in different tissues and under salt/drought stress was also determined. The presented information lays a good foundation for the following gene functional analysis of *NtCBL* genes.

CBL4 (also known as *SOS3*) is a well-known gene that was reported to play an important positive role in salt tolerance in many plant species. Therefore tobacco *NtCBL4A-1* was expected to play a role in the salt tolerance of tobacco. However, the expression of *NtCBL4A-1* was greatly inhibited by salt stress (Chapter 3), which does not seem consistent with the conserved role of *CBL4* in the salt tolerance of

other plant species. This may point to a different function of tobacco *NtCBL4A-1*. In order to understand the role of *NtCBL4A-1* in the salt stress response of tobacco, the *NtCBL4A-1*-overexpressing (*NtCBL4A-1*-OE) lines were evaluated for salt tolerance. In Chapter 3, results showed that the overexpression of *NtCBL4A-1* lead to a salt-supersensitive phenotype. There are three *NtCBL4* homoeologous genes (*NtCBL4A-1*, *NtCBL4A-2*, and *NtCBL4B*) in *N. tabacum*, and they may have functional redundancy given the high sequence similarity. Experiments involving loss-of-function mutants of *NtCBL4* may provide additional insight into the role of *NtCBL4* homoeologs in salt tolerance but I did not have enough time within the context of my PhD thesis to construct the single mutant of *NtCBL4A-1* nor the triple mutant of *NtCBL4*.

We also observed a salt-supersensitive phenotype in *NtCBL5A*-overexpressing (*NtCBL5A*-OE) lines (Chapter 4) (Mao et al., 2022), which is very similar to the phenotype we observed in *NtCBL4A-1*-OE lines (Chapter 3). Considering endogenous *NtCBL4A-1* is mainly expressed in roots (Chapter 3) and *NtCBL5A* is mainly expressed in veins and stems (Chapter 4) (Mao et al., 2022), we hypothesized that the salt-supersensitive phenotype of *NtCBL4A-1*-OE leaves and *NtCBL5A*-OE leaves may be caused by the ectopic overexpression of these genes, thus interrupting other CBL-CIPK pathways rather than the CBL-CIPK modules that *NtCBL4A-1* and *NtCBL5A* are endogenously involved in during the tobacco salt response. The phenotype of the loss-of-function mutant of *NtCBL5* (we evaluated the salt tolerance of *Nt-cbl5a*, *Nt-cbl5b*, and *Nt-cbl5acb15b* double mutant) is similar to the WT phenotype under salt stress, which confirms that *NtCBL5A* is not likely to be a key component in the salt tolerance of tobacco (Figure 1).

In the yeast-two hybrid experiment, we evidenced that *NtCBL4A-1*, *NtCBL5A*, and *NtCBL10A* can bind the same *NtCIPK* (Chapter 5). In addition, *NtCBL10A* overexpression was shown to relieve the salt-sensitive phenotype of *NtCBL5A*-OE lines, supporting our hypothesis that *NtCBL5A* overexpression may interfere with another CBL-CIPK (i.e. CBL10-CIPK) pathway. *NtCBL4A-1* overexpression was

shown to enhance the salt-sensitive phenotype of *NtCBL5A*-OE lines, indicating that overexpression of *NtCBL4A-1* and *NtCBL5A* may interfere with the same CBL-CIPK pathway. Therefore, we concluded that *NtCBL10* plays a key role in the salt tolerance of tobacco. Further stress tolerance assessment of the loss-of-function mutants of *NtCBL10* confirmed that *NtCBL10A* and *NtCBL10B* are key components in salt stress response (Chapter 5). Based on the two possibly independent salt-sensitive phenotypes (chlorosis and necrosis) of the *Nt-cbl10acb10b* double mutant under salt stress, we concluded that the knockout of *NtCBL10* may interfere with several physiological pathways, in line with the recent reports in the literature reviewed by Plasencia et al (2021). Because NtCIPK24 is a candidate partner of NtCBL10 in salt tolerance mechanisms of tobacco, we also evaluated the salt tolerance of *Nt-cipk24a* single and *Nt-cipk24b* single mutants (double mutant failed to be constructed because of a lethal callus). We detected slight salt sensitivity of the *Nt-cipk24a* and *Nt-cipk24b* single mutants and suggest that NtCIPK24 may indeed be one of the partners of NtCBL10 in salt stress response.

Figure 1. The editing ways of loss-of-function mutants of *NtCBL5* and the phenotype of plants under salt stress (100 mM NaCl) at 13 DAT (days after salt treatment). (A-D) The position of gRNA and protein translation of the edited sequence of *Nt-cbl5a* single mutant (A), *Nt-cbl5b* single mutant (B),

Nt-cbl5acb15b-1 double mutant (C), and *Nt-cbl5acb15b-5* double mutant (D). (E) The shoot phenotype of wild-type (WT), *Nt-cbl5a* single mutant, *Nt-cbl5b* single mutant, *Nt-cbl5acb15b* double mutant, and *NtCBL5A-OE-2* plants under salt treatment.

The versatile roles of *CBL10* and the salt-sensitive phenotypes of *Nt-cbl10acb10b* double mutant

CBL10 is considered to be a key master regulator of stress signaling and response under salinity, drought, flooding, and K⁺ deficiency stresses, by activating (in a CIPK-dependent manner) or repressing (by direct interaction) downstream targets in different subcellular locations (Plasencia et al., 2021). *CBL10* was shown to be involved in the regulation of the transport and distribution of several ions under salt stress, including not only Na⁺ but also H⁺, K⁺, and Ca²⁺ (Plasencia et al., 2021). This means that the homeostasis of not only Na⁺ but also other ions may be affected in a loss-of-function mutant of *CBL10*. In Chapter 5, we observed two possibly independent salt-sensitive symptoms (chlorosis and necrosis) of the *Nt-cbl10acb10b* double mutant under salt stress. The question that still needs to be answered is which *NtCBL10*-dependent adaptations to stress are underlying the different aspects of the salt-hypersensitive phenotype of the *Nt-cbl10acb10b* double mutant. Although we did not have time within the thesis project to target all the regulatory functions of *NtCBL10* in response to salt stress experimentally, the results give rise to highly interesting insights and hypotheses on *NtCBL10* functions under salt stress that are further discussed below.

The role of *CBL10* and the necrotic phenotype of *Nt-cbl10acb10b* double mutant

Na⁺ homeostasis

We found similar necrotic lesions in the *NtCBL5A-OE* and *Nt-cbl10acb10b* double mutant under salt stress (Chapter 4, Chapter 5). Even though we found that Na⁺ accumulation in both *NtCBL5A-OE* leaves and *Nt-cbl10acb10b* double mutant leaves were comparable to that of WT, Na⁺ accumulation may still play a role in the development of the necrotic lesions when the distribution of Na⁺ within the leaf and

leaf cells is considered. This hypothesis is based on the report that the tonoplast-localized CBL10-CIPK24 pathway positively regulates the Na^+ sequestration into the vacuole (Kim et al., 2007). If Na^+ transport to the vacuole is affected in the *Nt-cbl10acb10b* double mutant, Na^+ will accumulate to toxic levels in the cytosol much faster, and this may cause necrotic symptoms (Figure 2). In addition, AtCBL10 was also reported to interact with AtCIPK24 and AtCIPK8 (which has high sequence similarity with AtCIPK24, 60.9% AA pairwise identity), regulating Na^+ transport over the plasma membrane out of the cell (Quan et al., 2007; Lin et al., 2009; Kleist et al., 2014; Yin et al., 2019). If *NtCBL10* has the same function as *AtCBL10*, the loss-of-function of *NtCBL10* may also lead to impaired Na^+ extrusion, thus contributing to a higher relative Na^+ concentration in the cytosol (Figure 2).

The hypothesis of disturbed Na^+ homeostasis in the cytosol seems in line with the fact that the necrotic symptoms of *NtCBL5A*-OE lines and the *Nt-cbl10acb10b* double mutant under salt stress are light-dependent (Chapter 5). Plants grown under dark conditions transpire much less than plants grown under light, which will influence the transpiration flow. This is likely to affect the accumulation rate of Na^+ in the leaves: Na^+ is transported to the leaf blades with the transpiration stream and is deposited there under continuous salt stress, and only a small proportion of the Na^+ is recirculated to roots through phloem for most plants (Tester, 2003). Therefore, it is likely that the Na^+ accumulates faster in plant leaves under light conditions (with high transpiration flow) than under dark conditions, which is evidenced by the leaf Na^+ measurements in light and dark-treated leaves (Chapter 5, Figure 6E and 7D). In this case, the appearance of necrotic symptoms of *NtCBL5A*-OE lines and *Nt-cbl10acb10b* double mutant may be possibly delayed in dark conditions.

Cl⁻ homeostasis

In Chapter 5, it was shown that the *Nt-cbl10acb10b* double mutant accumulated significantly less Cl^- under salt stress compared to WT. This does not seem to be caused by less xylem flow/transpiration even though the stomatal conductance of *Nt-cbl10acb10b* double mutant is lower than that of WT (Chapter 5, Figure 5B and

5E), because the Na^+ accumulation between WT and mutant was not significantly different. Therefore, it may be related to Cl^- uptake in the roots or the efficiency of Cl^- root-to-shoot translocation. Although there is no report of CBL10 playing a role in Cl^- homeostasis, the CBL-CIPK network has been reported to regulate the Cl^- root-to-shoot translocation. AtCBL1/9-AtCIPK23 can activate the anion channel SLOW-TYPE ANION CHANNEL (SLAC1) in *Xenopus oocytes*, which is a PM-localized protein that is highly permeable to malate and chloride in guard cells (Maierhofer et al., 2014). SLAC1 has four homologues, which are the SLAC1-associated homologues 1 to 4 (SLAH1 to SLAH4). SLAH3 can also be activated by AtCBL1/9-AtCIPK23 in *Xenopus oocytes*, and it can form chloride-conducting heteromeric channels with SLAH1 in xylem-pole pericycle cells to regulate chloride root-to-shoot translocation (Maierhofer et al., 2014; Cubero-Font et al., 2016). AtCBL10 is reported to be able to interfere with AtCBL1/9-AtCIPK23 complexes by directly and competitively interacting with downstream targets. For instance, AtCBL10 competes with AtCBL1/9-AtCIPK23 in the interaction with AKT1 and repress the potassium uptake induced by AtCBL1/9-AtCIPK23 (Ren et al., 2013). Whether CBL1/9-CIPK23 also activates SLAC1 as well as its homologues (SLAH), and whether the reduced Cl^- accumulation in the leaves of the *Nt-cbl10acb10b* double mutant under saline conditions is linked to the lack of CBL10 regulation of this mechanism is still speculative (Figure 2).

For most plant species, Na^+ tends to reach a toxic concentration before Cl^- does, so Cl^- has received much less attention in salt tolerance research than Na^+ (Munns and Tester, 2008). For some species with woody stems and roots including soybean, grapevines, and citrus, Cl^- becomes the more toxic component under salt stress because the plant can manage the Na^+ transport better than Cl^- transport by effectively withholding Na^+ root-to-shoot translocation (Munns and Tester, 2008). Excessive Cl^- is considered toxic mainly because it is widely thought of as an antagonistic molecule of NO_3^- , an important source of nitrogen (Colmenero-Flores et al., 2019). Cl^- is a micronutrient for plant growth, working as an essential cofactor for

the oxygen evolution of the photosystem II and regulating cell osmolarity and the electrical charge balance of cations (Colmenero-Flores et al., 2019). Cl^- is a non-assimilating highly mobile anion and is preferred by plants to balance the electric charges of important cations to stabilize the electric potential of cell membranes and regulate pH gradients (Geilfus, 2018b; Colmenero-Flores et al., 2019). The chloroplast envelopes and the thylakoid membrane exhibit a high permeability for Cl^- (U and W, 1981; Bose et al., 2017) and Cl^- is the most abundant anion in the chloroplast stroma (50-90 mM) (Neuhaus and Wagner, 2000). Cl^- influx from the stroma to the lumen is essential for thylakoid swelling after the onset of illumination, and Cl^- re-export to the stroma would cause the thylakoid to shrink during the transition to darkness (Colmenero-Flores et al., 2019). In addition, the accumulated protons in the thylakoid lumen can be electrically counterbalanced by Cl^- influx, thus possibly regulating the pH gradient between the lumen and the stroma. Therefore, the disturbance of chloroplastidial Cl^- homeostasis might lead to the reduction of PS II (Geilfus, 2018a). In our study, the reduced rate of Cl^- accumulation in the *Nt-cbl10acbl10b* double mutant compared to WT under salt stress was reversed in the leaves grown in the dark (Chapter 5, Figure 6F and 7E), and the necrotic lesions disappeared. Whether there is any connection between Cl^- accumulation in *Nt-cbl10acbl10b* and the necrotic phenotype remains to be established, but it is interesting to explore.

Reactive oxygen species (ROS)

In Chapter 4, we found that ROS accumulation in *NtCBL5A*-OE leaves was higher than that in WT under salt stress already at 2 DAT (days after reaching 100 mM NaCl treatment) and 6 DAT (Chapter 4, Figure S2 and 4D) (Mao et al., 2021). Under salt stress, the Calvin cycle is inhibited by salinity-induced stomatal limitation, leading to the over-reduction of the electron transport chain and the generation of ROS (Attia et al., 2009; Hajiboland, 2014). Possibly, the light energy input in *NtCBL5A*-OE leaves may exceed energy utilization when the Calvin cycle is more inhibited than the light reaction in the photosynthesis of *NtCBL5A*-OE leaves under salt stress.

Therefore, the resulting ROS generation in *NtCBL5A*-OE leaves might exceed the ROS scavenging ability, leading to necrotic lesions. Even though we do not have ROS accumulation data of the *Nt-cbl10acb10b* mutant under salt stress, it is not unlikely that ROS species also accumulated in *Nt-cbl10acb10b* double mutant. Our results showed that the stomata conductance of *Nt-cbl10acb10b* double mutant was more severely inhibited by salt stress since 1 DAT (Chapter 5, Figure 6). This stomatal limitation may cause an enhanced imbalance between ROS production and scavenging at the very early stage of salt treatment, thus leading to the necrotic symptom of the *Nt-cbl10acb10b* double mutant.

Figure 2. Schematic picture to show the pathways that *NtCBL10* may be involved in by activating (in a CIPK-dependent manner) or repressing (by direct interaction) downstream targets in different subcellular locations. Exo CBL4/5 means overexpressed exogenous *NtCBL4/5*. Pointed and blunt arrowheads indicate activating and inhibitory processes, respectively. The dotted lines indicate proposed connections that still require validation. The question mark (?) means the Na^+/H^+ antiporter has not been identified yet. The red lightning sign with a “P” inside means phosphorylation.

The role of *CBL10* and the chlorotic symptom of *Nt-cbl10acb10b* double mutant

The chlorosis symptom of *Nt-cbl10acb10b* double mutant is light-independent, in contrast to the light-dependent chlorotic spots on *NtCBL5A*-OE leaves. Although we cannot rule out a role for cytosolic Na⁺ accumulation in the development of the chlorotic symptoms, the low rate of leaf Na⁺ concentration increase in the *Nt-cbl10acb10b* double mutant grown in the dark while chlorotic symptoms still developed very fast suggests that Na⁺ accumulation itself is not causal to the chlorosis and fast breakdown of chlorophyll. So then the question remains: what causes the extreme and fast-developing chlorosis in the *Nt-cbl10acb10b* double mutant?

6

CBL10 also appears to be involved in the regulation of H⁺ homeostasis by amongst others affecting the activity of the vacuolar H⁺-ATPase (V-ATPase, VHA) and the vacuolar H⁺-pyrophosphatase (V-PPase, AVP1), which are two vital proton pumps in the tonoplast for energizing ion transport (Figure 2) (Hedrich et al., 1989). VHA consists of two subcomplexes which are the peripheral V₁ complex (eight subunits VHA-A to -H) for ATP hydrolysis and the membrane-integral V₀ complex (VHA-a, -c, -c', -c'', -d, and -e) for proton translocation (Cipriano et al., 2008). AtCIPK24 was reported to interact with the peripheral VHA-B subunits and stimulate H⁺ transport activity (Batelli et al., 2007). In addition, in a tomato *Sl-cbl10* mutant, the gene expression of the vacuolar H⁺ pumps *SlAVP1* and *SlVHA-A1* was downregulated under saline conditions compared to WT (Egea et al., 2018), suggesting *SlCBL10* affects H⁺ homeostasis, possibly as a driver for Na⁺ compartmentation into the vacuole. Therefore, CBL10-CIPK24 may contribute to Na⁺ compartmentation by stimulating the tonoplast-localized proton pumps (regulating the H⁺ homeostasis) (Figure 2). Furthermore, AtCBL10 was also suggested to negatively regulate the activity of AtAHA4 and AtAHA11 in an AtCIPK-independent manner by direct interaction (Figure 2) (Xie et al., 2022). Impaired regulation of the H⁺ pumps under saline conditions may result in impaired H⁺ homeostasis and pH regulation, which

can be highly damaging to the leaf cell functioning, and even induce chlorophyll breakdown (Long et al., 2017). Whether impaired pH regulation is causal to the fast-developing chlorosis in the *Nt-cbl10acb10b* double mutant under salt stress remains to be established.

Interestingly, a VHA-deficient *det3* mutant showed severe salt sensitivity (Batelli et al., 2007), but this salt sensitivity was evidenced later to be caused by reduced VHA activity in the trans-Golgi network/early endosome (TGN/EE) but not at the tonoplast. A loss-of-function mutant of *VHA-a2* and *VHA-a3* (two VHA-a isoforms localized in the tonoplast) did not show salt sensitivity and still accumulated Na^+ , while the loss-of-function of *VHA-a1* (an isoform localized in the TGN/EE) was salt-supersensitive (Krebs et al., 2010). The TGN/EE is an organelle with complex cellular roles, one of which is sorting and delivering proteins to the apoplast, PM, and vacuole. Plant cells always maintain a low luminal pH and the impaired TGN/EE pH regulation may lead to severe plant growth defects (McKay et al., 2022). These reports proposed a key role for H^+ homeostasis in the endosomal system that also greatly affects the salt tolerance of plants.

The VHA is often found to be co-localized with a specific member of the Cl^- channel (CIC) family of anion transporters (Scholl et al., 2021). CICd and CICf are two H^+/Cl^- antiporters that are colocalized with VHA-a1 in the TGN/EE and regulate the pH in the Golgi stack (Scholl et al., 2021). In addition, plant TGN/EE pH regulation requires the cation chloride cotransporter (CCC) that electroneutrally transports Cl^- across membranes with the cations Na^+/K^+ (McKay et al., 2022). These results showed that Cl^- homeostasis directly relates to and contributes to H^+ homeostasis and Na^+ homeostasis of the TGN/EE. The imbalanced accumulation of Na^+ and Cl^- in *Nt-cbl10acb10b* may also lead to interfered H^+ homeostasis in the TGN/EE system of tobacco and thus to severe plant defects.

Interestingly, CBL10 was also found to directly interact with and repress the TOC34 protein (Figure 2), a member of the TOC (translocon of the outer membrane of the chloroplasts) complex with GTPase activity to regulate protein import into

chloroplasts (Cho et al., 2016). This study evidenced the subcellular localization of CBL10 in the chloroplast and indicated that *CBL10* may play a role in chloroplast functions, which seems in line with our result that the knockout of *NtCBL10* leads to chlorophyll breakdown and PS II defects under salt stress. The importance of maintaining ion homeostasis in the different cellular organelles under salt stress conditions may be underestimated, and the putative role of CBL-CIPK network components in the correct functioning of these organelles under stress conditions is certainly worth exploring.

Considerations when using gene overexpression and gene knockout lines for gene characterization

6

Overexpressing a gene in the same species or another (model) species is a widely used strategy to explore gene function as a parallel approach to gene loss-of-function mutants (by silencing or knocking out genes). The expectation often is that overexpression and knockout/silencing of a gene will cause opposite phenotypes. However, that does not have to be the case. In practical experiments, overexpression may even cause the same phenotype with loss-of-function or no phenotype (Prelich, 2012), especially when the gene is expressed under a constitutive promoter that drives expression in all tissues, developmental stages, and conditions. The overexpression of a gene, in particular for the gene whose expression is normally limited to specific conditions or specific cell types, can cause inhibition or activation of a protein complex or pathway that it normally would not interact with (Prelich, 2012). Most examples of the inhibitory effect of gene overexpression involve protein-protein competitive interactions, inhibiting the original complex or pathway by competing with their interacting member (Prelich, 2012). The overexpression phenotype induced by competition-based mechanisms can be reversed by co-overexpression of the target protein (Prelich, 2012). In this thesis, we found that overexpression of *NtCBL5A* led to a supersensitivity phenotype under salt stress. However, the gene expression profile of *NtCBL5A* and the salt tolerance assessment results of *Nt-cbl5acb15b* double mutant seem to confirm that the *NtCBL5* is not a key

component in salt stress tolerance of tobacco, and that the salt-sensitive phenotype of the *NtCBL5A*-OE lines is likely not related to its endogenous function. This shows that caution is required in deducing gene functions from overexpression phenotypes. At the same time, however, overexpression phenotypes can be highly insightful when interpreted correctly, as is also exemplified in this thesis. The proposed interference of *NtCBL5A* overexpression based on the salt-sensitive phenotype enabled us to hypothesize on the different activities of *NtCBL10* and the physiological processes underlying the salt hypersensitivity with fast-developing chlorosis and necrosis of the loss-of-function mutant of *NtCBL10*.

Gene loss-of-function mutants have been widely accepted as a convincing material to explore real gene functions. It is important to keep in mind that the mutant phenotype could be a combined result that attributes to several interfered signaling pathways, especially when this gene has versatile functions such as *NtCBL10* in this thesis.

Na⁺-imaging technique for detecting Na⁺ distribution in the cell is needed for our further studies

Whether Na⁺ accumulation can be directly responsible for the salt sensitivity of *NtCBL4A-1*-OE lines, *NtCBL5A*-OE lines, and the *Nt-cbl10acb10b* double mutant remains to be established. I only measured ion contents in the whole leaf blades. Disturbed distribution of Na⁺ at the cellular level may result in highly elevated Na⁺ concentrations in the cytosol and the chloroplast, even when the total Na⁺ content of the leaf is not much different from that in WT. It would be highly insightful to be able to quantify ion contents in the different cellular compartments, and understand how the cellular distribution of the ions is affected in the *NtCBL* transgenic lines.

Future experiments therefore may be considered that use a Na⁺ indicator with a high-resolution confocal imaging technique. A commonly used Na⁺ indicator is CoroNA Green dye. Na⁺ measurement by CoroNA Green fluorescent dye imaging was first conducted in animals (Meier et al., 2006). In 2015, Wu (Wu et al., 2015) published a protocol for quantifying Na⁺ distribution between cytosol and vacuole of root cells by

CoroNa Green fluorescent dye imaging (Wu et al., 2015). By co-staining the plant cells with CoroNa Green-AM and FM4-64, another dye that stains both plasma and vacuolar membranes, a better resolution of Na^+ -imaging can be obtained to observe the intracellular compartments (Wu et al., 2015). Then the cytosolic and vacuolar Na^+ fluorescent intensities are used to represent Na^+ concentration (Wu et al., 2015; Wu et al., 2018). This type of experiment will allow us to see whether *NtCBL10* is essential for the correct distribution of Na^+ in the (intra)cellular compartments, and whether the *NtCBL4A-1* and *NtCBL5A* overexpression interferes with this specific *NtCBL10* activity.

Low Na^+ might be used as nutrition for the tobacco growth

6

In our studies of salt treatment on tobacco, we found that WT tobacco growth was significantly inhibited under 100 mM NaCl. However, we also found in our experiments that tobacco had a significantly better growth vigor under very mild NaCl treatments (10 mM, 25 mM) than under control conditions at 9 DAT (Figure 3). There is substantial evidence that lower levels of Na^+ supply is of potential benefit to the normal growth and development of some species with moderate to high salt resistance (Slama et al., 2007; Subbarao et al., 2010; Gattward et al., 2012). Na^+ may be capable of replacing K^+ as internal osmoticum, stomatal function, photosynthesis, counter-ion in long-distance transport, and enzyme activation, the extent of which varies between plant species (Subbarao et al., 2010). The vacuolar K^+ is replaceable to a large extent by Na^+ because this osmotic function is nonspecific, and this replacement within the vacuole makes K^+ available for specific functions within the cell or for translocation (Marschner, 1971). This is thought to be the reason why Na^+ contributes to the osmotic relations and the mineral nutrition in moderate to high salt-tolerant plants (having the ability to accumulate large amounts of Na^+ in vacuoles), especially if K^+ is present at suboptimal levels (Wakeel et al., 2010). Growth stimulation by low levels of Na^+ attracts both practical and scientific interest because of the potential to utilize Na as inexpensive fertilizer. The underlying mechanism of growth stimulation by Na^+ in the relatively salt tolerance crop tobacco

has never been reported, but it would be interesting to investigate this.

Figure 3. The shoot phenotype and physiological indicators of wild-type (WT) under control conditions and different salt stresses. Scale bars=10 cm. (A) The shoot phenotype of WT under control conditions and different salt stresses at 9 DAT. (B-E) The plant height, shoot fresh weight, 5th leaf length, and 5th leaf width of WT. Error bars indicate \pm SD ($n=9$). (F-I) The Na^+ , K^+ , Ca^{2+} , and Mg^{2+} contents of the 5th leaves of WT tobacco. Error bars indicate \pm SD ($n=3$). Different letters above bars (a, b, and c) indicate significant statistical differences based on one-way ANOVA with LSD test ($P<0.05$).

“Tolerant” or “Sensitive” is a relative term and should be restricted to specific evaluation criteria or situation

Plant tolerance is often defined as the degree to which the plant can withstand moderate or severe stress without significant adverse effects. However, plant tolerance is a relative term in practice. Researchers often assess and describe “tolerant” or “sensitive” based on the plant performance that is specific to their particular studies. But several points need to be considered to evaluate plant tolerance.

First, stress tolerance or sensitivity is affected by developmental stages. For instance, rice is salt-sensitive at two growth stages: the seedling stage and the reproductive stage. The salt sensitivity of rice at these two stages is controlled mostly by different sets of genes (Singh et al., 2010). The salt tolerance of rice at the reproductive stage is directly associated with rice yield (Palao et al., 2013). Therefore, a genotype with salinity tolerance at the seedling stage does not mean it is tolerant at the reproductive stage as well nor makes sure of a good rice yield, and vice versa (Ahmadizadeh et al., 2016). Second, “tolerant” or “sensitive” are determined based on agronomic traits. However, different agronomic traits may be needed with different breeding objectives. For example, the tolerance screening based on plant vigor may only identify the cultivars or breeding lines with non-dwarf plant types (Zeng et al., 2002). In addition, some traits which are disliked by breeders may contribute to survival and reproduction, which could be considered tolerant from a plant’s perspective. For instance, plants may allocate Na^+ to old leaves, thus reducing Na^+ accumulation when old leaves die and be shed to protect the young leaves (Tester and Davenport, 2003). Therefore, the necrosis of old leaves is not necessarily a clue of salt sensitivity. Moreover, traits associated with tolerance may have a dual effect. For example, most traits associated with drought tolerance are positive in very severe scenarios and negative in milder scenarios, or the opposite trend (Tardieu, 2012). Therefore, spectacular results obtained in one drought scenario may have limited interest in improving food security in other geographical areas with water scarcity. Therefore, the description of “tolerant” or “sensitive” should be restricted to specific criteria or situations.

From an agronomical point of view, stress tolerance should mean (relatively) high yield and quality under stress conditions. For *Solanaceae*, that could mean leaves (tobacco), fruits (tomato), or tubers (for potato). In other words, breeding for different crops has different criteria for “tolerance”. As researchers, we often define a stress-tolerant plant as a plant with the least reduction in biomass/yield when grown under stress conditions compared to the biomass/yield under normal ideal conditions. Any

genotype that is able to maintain growth may have very interesting stress tolerance traits that can contribute to higher yield, no matter whether it is the one with the highest yield under stress. For breeders, however, stress-tolerant varieties often should have high yields under stress as well as under normal conditions. Many genes that are responsible for stress tolerance and are proposed as targets for improving stress tolerance of crops may also be involved in plant development via direct involvement or indirect physiological connection, thus leading to a trade-off between stress tolerance and yield (higher tolerance under stress conditions but lower yield under normal conditions). This may be the main reason why only very few salt-tolerant genes identified in the lab have been successfully used for improving stress tolerance without yield penalties in the field trials, even though numerous stress-tolerant genes were reported based on lab experiments. Aligning and/or managing expectations with respect to stress tolerance between scientists, breeders, and growers is therefore important. Scientists may need to carefully select traits with a minimal trade-off, or investigate the effects of a combination of traits in the same variety to minimize growth trade-offs and fulfill the requirement of breeders and growers.

Possible breeding strategies targeting *CBL* genes

Genome-editing based on the CRISPR-Cas technique is regarded as a highly efficient plant breeding technology, especially with the development of non-transgenic genome editing techniques. Yang et al (2023) designed fusions of Cas9 and guide RNA transcripts to tRNA-like sequence motifs that can move RNAs from transgenic rootstocks (*Arabidopsis*) to grafted WT scions (*Arabidopsis* or *Brassica rapa*) and achieve heritable gene editing. In addition, an engineered biocontainable RNA virus (TSWV) was also developed to deliver CRISPR/Cas nucleases to achieve non-transgenic heritable mutations without tissue culture (Liu et al., 2023). With these state-of-the-art genome editing techniques, different combinations of favorable alleles and flexible regulation of the combinations may be helpful to make considerable progress in stress tolerance breeding (transgene-free).

Could *CBL* genes be eligible as targets for improving the stress tolerance of crops? *AtCBL10* was reported to have a contrasting function in drought stress tolerance versus salt stress tolerance in *Arabidopsis*. The *At-cbl10* mutant exhibited a higher drought tolerance than WT with an unknown mechanism until now (Kang and Nam, 2016), so knocking out of *AtCBL10* may result in a line for improved drought tolerance but decreased salt tolerance. In this case, the best strategy might be to modify gene expression or protein function rather than knocking out the gene. Possibly, the native promoter of *CBL10* can be replaced by a salt stress-inducible promoter to make sure that *CBL10* still exerts its essential role during salt stress, while having low or no expression under normal and/or drought conditions. For allopolyploid plants like tobacco, knocking out only one of *NtCBL10* homoeologs (*NtCBL10A* or *NtCBL10B*) may be a possible alternative to enhance drought tolerance while hardly affecting the salt stress response. As described, *AtCBL10* has diverse functions, at least partly attributed to its different subcellular localizations (PM, tonoplast, chloroplast, and membrane vesicles) (Quan et al., 2007; Batistic et al., 2010). The tonoplast association of *AtCBL10* requires S-acylation of the C residue at position 38 and contributes to salt tolerance (Chai et al., 2020). The substitution of this C residue to Ser (S) in *AtCBL10* leads to cytoplasmic and nuclear localization and dysfunction under salt stress (Chai et al., 2020). This demonstrates that inducing targeted mutations to modify the subcellular location of proteins can be a strategy to modify the protein functions. The precondition for this is we have a detailed understanding of how the protein works in different subcellular locations. With respect to fine-tuning different activities, the multiple splicing variants for *CBL* genes may provide an additional tool (Mao et al., 2022). Overexpressing or knocking out specific splice variants could result in functional moderation of *CBL* functions. However, a more detailed functional characterization of these splicing variants would be required first.

Concluding remarks

In this thesis, I conducted the genome-wide analysis of *CBL* family gene in

allotetraploid tobacco, obtaining a comprehensive understanding of the sequence, protein characteristics, and gene expression profiles of *NtCBL* family genes. Overexpression of *NtCBL4A-1* and *NtCBL5A* led to salt supersensitivity of transgenic tobacco, which may be because the ectopic overexpression of them interfered with the function of other *NtCBL*s. In the end, *NtCBL10* was evidenced to play a vital role in salt tolerance. In addition, NtCBL10-interacting NtCIPK24 also contributes to salt tolerance. This study provides data for the functional identification of *CBL* genes and the selection of candidate stress-tolerant genes in *N. tabacum*, which will likely be useful for the genetic improvement of *Solanaceae* crops in general. In addition, this thesis provides insight into the physiological roles of the CBL-CIPK network in the crosstalk between plant growth and stress adaptation, and the crosstalk between homeostasis regulation of different ions, enhancing the knowledge of the mechanisms underlying salt stress response of plants.

Summary

Summary

Ca^{2+} transients in the cytosol ($[\text{Ca}^{2+}]_{\text{cyt}}$) act as major physiological signals to initiate appropriate responses. The CBL-CIPK network decodes $[\text{Ca}^{2+}]_{\text{cyt}}$ transients that are initiated during plant development and in response to environmental changes. Several functions of the CBL-CIPK regulatory network have been identified in more detail in the model plant *A. thaliana*, but much less is known about their functions in solanaceous crops.

Chapter 1 introduced the CBL-CIPK network and current knowledge on how it decodes Ca^{2+} transients triggered by stress stimuli. It summarized current knowledge on salt stress response mechanisms and the role of CBL-CIPK modules in the regulation of these mechanisms.

Chapter 2 is a review that describes how the CBL-CIPK regulatory network is involved in two levels of crosstalk between plant development and stress adaptation: direct crosstalk through interaction with regulatory proteins, and indirect crosstalk through adaptation of correlated physiological processes that affect both plant development and stress responses. This chapter thus provides novel insights into the physiological roles of the CBL-CIPK network in plant growth and stress adaptation and the trade-off between plant growth and stress response.

In **Chapter 3**, a genome-wide analysis of the *NtCBL* gene family in tobacco was performed. Twenty-four *NtCBL* genes were identified in *N. tabacum*, of which 14 *NtCBL* genes were derived from the maternal genome donor *N. sylvestris* and 10 from the paternal genome donor *N. tomentosiformis*. Based on their sequences we predicted the subcellular localization and Ca^{2+} -binding ability of *NtCBL* proteins, as well as gene structure and splicing variants of *NtCBL* genes at the level of individual homoeologs. In addition, the expression profiles of *NtCBL* genes were determined in different tissues and at different developmental stages, as well as under salt and drought stress. The *NtCBL4A-1* gene from the ancestral *N. sylvestris* genome was characterized in more detail because of its reported role in the salt stress response of other plant species but its deviating expression response in tobacco from that of other species. Results showed that the overexpression of *NtCBL4A-1* led to a salt-

supersensitive phenotype. There are three *NtCBL4* homoeologous genes (*NtCBL4A-1*, *NtCBL4A-2*, and *NtCBL4B*) in *N. tabacum*, and they may have functional redundancy because of their high sequence similarity. Experiments involving loss-of-function mutants of *NtCBL4* may provide additional insights into the role of *NtCBL4* homoeologs in salt tolerance but I did not have enough time within the context of my PhD thesis to construct the single mutant of *NtCBL4A-1* nor the triple mutant of *NtCBL4*.

In **Chapter 4**, we focused on another member of the CBL family that was suggested to play a role in salt tolerance: CBL5. Tobacco plants overexpressing *NtCBL5A* were evaluated under saline conditions and exhibited hypersensitivity to salt stress (expressed as highly necrotic leaves). This hypersensitive phenotype was shown to be potentially linked to abnormal Na⁺ compartmentalization, plant photosynthesis, and plant immune response triggered by the constitutive overexpression of *NtCBL5A*. The salt-supersensitive phenotype of *NtCBL5A*-overexpressing (OE) lines was very similar to the phenotype we observed in *NtCBL4A-1*-OE lines under salt stress. Considering that both *NtCBL4A-1* and *NtCBL5A* were ectopically overexpressed in the leaf blades of these transgenic plants, we hypothesized that the salt-supersensitive phenotype of *NtCBL4A-1*-OE leaves and *NtCBL5A*-OE leaves may be caused by interference with other CBL-CIPK pathways rather than their native functions in salt stress response. The response to salt stress of the loss-of-function mutant of *NtCBL5* (*Nt-cbl5a*, *Nt-cbl5b*, and *Nt-cbl5acb15b* double mutant) was later shown to be similar to WT plants (Chapter 6), confirming that *NtCBL5A* does not appear to be a key component in the salt tolerance of tobacco

In **Chapter 5**, we further investigated the salt-supersensitive response of *NtCBL4A-1*-OE and *NtCBL5A*-OE lines and the possible interference with other CBL-CIPK pathways. We evaluated the salt tolerance of *NtCBL4A-1::NtCBL5A* co-overexpressing lines and *NtCBL10A::NtCBL5A* co-overexpressing lines. Results showed that co-overexpression of *NtCBL4A-1* and *NtCBL5A* had an additive effect on the salt sensitivity of transgenic tobacco, while *NtCBL10A* overexpression greatly

Summary

relieved the salt sensitivity of *NtCBL5A*-OE lines. This indicated that the salt sensitivity caused by *NtCBL4A-1* overexpression and *NtCBL5A* overexpression may be linked to the function of *NtCBL10A*. This was corroborated by the fact that *NtCBL4A-1*, *NtCBL5A*, and *NtCBL10A* interacted with the same *NtCIPK24A* in the yeast two-hybrid system. Increased salt sensitivity of *Nt-cbl10a* single mutants and *Nt-cbl10b* single mutants, and the hypersensitivity of the *Nt-cbl10acb10b* double mutants further demonstrated that *NtCBL10A* and *NtCBL10B* are essential for the salt tolerance of tobacco. The *Nt-cipk24a* and *Nt-cipk24b* single mutants also showed increased salt sensitivity compared to WT. We were however not able to obtain the *Nt-cipk24acipk24b* double mutant because of defective callus development.

In **Chapter 6**, I summarized all findings and discussed our hypothesis on the salt-sensitive phenotypes induced by the overexpression of *NtCBL4A-1*, *NtCBL5A*, and the knock-out of *NtCBL10*. Our results indicated that two possibly independent salt-sensitive phenotypes (chlorosis and necrosis) of the *Nt-cbl10acb10b* double mutant are exhibited under salt stress, and the salt sensitivity of *NtCBL4A-1*-OE and *NtCBL5A*-OE lines may link to the necrotic symptoms of *Nt-cbl10acb10b* under salt stress. The question that still needs to be answered is which *NtCBL10*-dependent adaptations to stress are underlying the different aspects of the salt-hypersensitive phenotype of the *Nt-cbl10acb10b* double mutant. I did not have time within this thesis project to add data targeting all the regulatory functions of *NtCBL10* in response to salt stress, but I discussed the results based on the available literature. The necrotic symptoms of *Nt-cbl10acb10b* double mutant may be linked to disturbed Na^+ homeostasis, Cl^- homeostasis, and ROS production. I hypothesized that the fast-developing chlorotic symptoms of *Nt-cbl10acb10b* double mutant may be caused by abnormal regulation of H^+ homeostasis in the plasma membrane, tonoplast, and trans-Golgi network/early endosome. Further experiments are needed to test these intriguing hypotheses. Finally, I discussed the results of this thesis in the context of breeding for abiotic stress tolerance and the improvement of crops.

Acknowledgments

Time flies! As I sit here reflecting on my PhD experience, I am filled with complex emotions—both excitement for the intriguing discoveries and frustration with the intricate results. Life is full of ups and downs that can make you laugh or cry. Throughout this journey, I have come to realize that the people who have supported me, loved me, and worked alongside me are the most important part of my life. Therefore, I would like to express my heartfelt gratitude to those who have cheered for my achievements and encouraged me during difficult times.

I am fortunate to have encountered many kind and knowledgeable supervisors, and I would like to express my sincere gratitude towards them first in the order of our acquaintance.

Prof. Dr. Haobao Liu, thank you for your guidance and encouragement during the critical junctures of my studies. Our journey together began almost a decade ago in September 2013, and since then, your selfless dedication to learning and commitment to elevating your students to greater heights has had a profound impact on me. You supported me to apply for the PhD Education Programs jointly offered by the Graduate School of Chinese Academy of Agricultural Science and Wageningen University & Research. This decision has proven to be one of the most pivotal in my life, as it opened up numerous opportunities to interact with exceptional researchers, forge lasting friendships, and acquire invaluable techniques that have become a treasure trove in my personal and professional development. You are not just a supervisor to me, but a true mentor who has played an instrumental role in shaping my trajectory. I have always admired your leadership style and your unwavering commitment to excellence. Your wife, doctor **Zhaomei Yang**, has also been incredibly supportive and caring towards me in my daily life - preparing delicious meals for us, organizing team-building activities, and even sending medicine when I fell ill. I am truly grateful for everything you and your wife have done for me.

Prof. Dr. Qian Wang, I would like to express my sincere gratitude for your meticulous guidance and assistance in experimental operations and design. Your rigorous and

serious academic style, as well as your passion for scientific research, have deeply influenced me. As the saying goes, “Sneaking into the night with the wind, silently moistening things”. Your dedication to your work has left a lasting impression on me. I will always remember your earnest teachings and strive to continuously improve myself in my future pursuit of scientific research.

Prof. Dr. Richard G.F. Visser, thanks for your invaluable help and guidance throughout my PhD project, as well as for providing me with the opportunity to pursue my studies at WUR. I still recall the day when I sent a brief email via the contact box on Plant Breeding’s website, inquiring about potential admission to the PhD Education programs between GSCAAS and WUR. My email read, “Dear Richard, I am currently working on functional gene identification in response to salt stress, would you be interested in knowing more about me?” At that time, I was uncertain whether my message would reach you among the deluge of correspondence you receive on a daily basis. Furthermore, I was not sure if you would entertain the idea of contacting someone without prior knowledge of their background. However, your discerning consideration was evident through the prompt response from Prof. Dr. Yuling Bai shortly after I dispatched my initial message. Yuling conveyed that she was acting on your behalf in requesting a copy of my curriculum vitae for evaluation purposes.

Prof. Dr. Yuling Bai, I am immensely grateful for your unwavering encouragement and support since our first contact. Your positive feedback after reviewing my CV and subsequent arrangements to meet me in Beijing, China, and treat me and Xiaoxiao to a lovely dinner near CAAS was a defining moment for me. During the meeting, I had the privilege of discussing my research topic for my master’s thesis with you, which turned out to be a stimulating discussion. You played an instrumental role in assisting me with my CSC scholarship and visa application process. I still remember the moment when you picked me and Menghe up from the reception on the first day of my arrival at WUR. Your elegance, warmth, and rigorous academic spirit, combined with an unwavering fighting spirit, have been an inspiration to me. I am truly grateful for your invaluable assistance and insightful suggestions on my PhD

Acknowledgments

project, especially for introducing me to Gerard – my exceptional research partner and daily supervisor.

Dr. C. G. Gerard van der Linden, I am deeply grateful for the extensive guidance and support you have provided me throughout my PhD study. I remember vividly the day we first met, with you fully absorbed in your writing as Yuling led me into your office. At that moment, I felt a bit nervous and uncertain, as we had never met or interacted before. However, your kindness, understanding, and unwavering support quickly helped me feel at ease, and we established a weekly meeting routine to discuss my research progress. Prior to working with you, I had always struggled with making detailed plans and preferred to conduct experiments as quickly as possible. During our early meetings, you patiently guided me in the process of creating detailed experimental plans and perfecting them step by step, resulting in significant time savings and improved efficiency. Even when I returned to China, we maintained regular online meetings to continue the progress. I will never forget your support during a difficult period when you were suffering from a serious health problem, yet you still helped me with my first paper. Despite the challenges, we persevered and completed a successful paper, and subsequent papers became easier to write as we worked together. Your talent for concise and innovative storytelling proved invaluable in reviewing papers, as we reorganized my review and produced exceptional work. As the deadline for my thesis approached, we worked together more efficiently than ever before, and we completed the work to an excellent standard. You taught me to read literature critically and carefully analyze conclusions, and your passion for science and love of puzzles have been truly inspiring throughout my research journey. Thank you for being an outstanding supervisor and mentor.

My dear paranymphs, **Alejandro** and **Yingjie**, I would like to express my sincere gratitude for accepting my invitation to be my paranymphs. Despite our relatively short acquaintance, I found talking to both of you very comforting as you both have been kind, friendly, and helpful to me. **Alejandro**, I am impressed by your expertise in bioinformatics, and I appreciate your remarkable efficiency in your work. It is no wonder that you are popular in Plant Breeding and have many friends around you.

Yingjie, your cheerful and enthusiastic personality always warms my heart, and I enjoy talking to you very much. I am confident that we can develop a strong and lasting friendship.

Dr. Susan Urbanus, you have been an incredibly supportive PhD advisor. Your warm and patient nature, coupled with your willingness to always listen and provide the best problem-solving strategies, has been invaluable to me throughout my program. I am also grateful to **Sean** and **Martijn**, who were instrumental in helping me with my hydroponic experiments. Without your assistance, the experiments would not have been completed so seamlessly. And last but not least, **Annemarie**, thank you for your help with the ion content measurement. Although I encountered obstacles in the beginning, your guidance and support were instrumental in enabling me to complete all the measurements successfully.

I would like to express my heartfelt gratitude to all my colleagues at CAAS, particularly **Lianhong Dong, Sujuan Shi, Yulong Su, Ge Zhang, Shugui Li, Chuanzong Li, Guang Yuan, Shuaijun Deng, Zhijie Mo, Jiaping Yuan, Kaiyan Han**, and the entire team at Tobacco Research Institute of CAAS. Working alongside you has been a pleasure and an honor. From sharing meals and conducting experiments together, to playing and laughing together, you have made me feel like part of a warm and supportive family. I am grateful for the camaraderie and friendship that we have shared, and I will always cherish the memories of our time together.

I would also like to thank all my colleagues at WUR, particularly **Robert, Elly, Lucia, Clemens, Johan**, and the entire group of Breeding for Abiotic Stress Tolerance. It was a pleasure to attend the weekly group meetings, where we discussed scientific topics and caught up on each other's recent activities. Your expertise and knowledge have been invaluable to me, and I am grateful for the opportunity to learn from each of you.

My dear friend **Sri (Artik)**, I am grateful for your guidance and support during my early days at WUR. You patiently introduced me to the lab and greenhouse rules, and even accompanied me on grocery shopping trips, familiarizing me with the

Acknowledgments

various stores and their unique features. Our shared cooking experiences and enjoyable meals were a highlight of my time abroad, and your sisterly advice and care have been invaluable.

To my dear Chinese friends in Wageningen, including but not limited to **He Meng, Xiaoxiao Xie, Qian Li, Lina Hu, Yusi Liu, Lei Deng, Dazhi Liu, Panpan Fan, Qingbo Qu, Dong Zhang, Xulan Wang** (in no particular order 😊), I am grateful for your support and assistance during my time in Wageningen. Our shared cooking and chatting moments were filled with joy and warmth, and I am grateful for the treasured memories we have created together.

To my beloved boyfriend, I am grateful for your companionship and the serendipitous encounter that brought us together. Your admirable qualities of gentleness and erudition have drawn me to you, and our relationship continues to be filled with sweetness. We did have disagreements at times, but each time we were able to understand each other better. I sincerely hope that we can continue to share our love for many more years to come.

I want to thank my parents for their boundless love and guidance, which have been a source of strength and inspiration for me. I am also thankful for giving birth to my younger brother, who has brought joy and companionship into my life, and our shared similarities and interests have made our conversations lively and fulfilling. I know that we will continue to support and love each other throughout our lives.

In the end, I want to acknowledge myself for the strength and determination that I have cultivated throughout this journey. I have learned to trust and believe in myself, and to strive for personal growth and excellence. As I look forward, I am committed to embracing life with enthusiasm and dedication, and to pursue my happiness to the fullest.

Jingjing Mao

April 2023 in Wageningen

About the Author

Jingjing Mao was born on February 12, 1992 in Anyang, Henan Province. In 2014, she obtained her bachelor degree at the Henan Agricultural University, Zhengzhou, China. After that, she was recommended by her university to be a master at Tobacco Research Institute of Chinese Academy of Agricultural Science without examination. In 2017, she was admitted as a PhD candidate to the joint PhD Program of the Graduate School of Chinese Academy of Agricultural Science and that of Experimental Plant Sciences of Wageningen University & Research. Her research is mainly focused on the functional identification of key *CBL* and *CIPK* genes in salt stress response of tobacco. This thesis presents the outcomes of her PhD research on “The role of *CBL* genes in the salt stress response of *Nicotiana tabacum*”.

Publications by the author

Mao J, Yuan G, Han K, et al., Genome-wide identification of *CBL* family genes in *Nicotiana tabacum* and the functional analysis of *NtCBL4A-1* under salt stress. **Environmental and Experimental Botany**. 2023. 105311.

Mao J, Mo Z, Yuan G, et al., The CBL-CIPK network is involved in the physiological crosstalk between plant growth and stress adaptation. **Plant, Cell & Environment**, 2022.

Mao J, Yuan J, Mo Z, et al., Overexpression of *NtCBL5A* leads to necrotic lesions by enhancing Na⁺ sensitivity of tobacco leaves under salt stress. **Frontiers in Plant Science**, 2021, 12: 18-36.

Education Statement of the Graduate School

Experimental Plant Sciences

Issued to: Jingjing Mao
 Date: 13 June 2023
 Group: Plant Breeding
 University: Wageningen University & Research

1) Start-Up Phase	<u>date</u>	<u>GP</u>
► First presentation of your project Mechanisms and physiological roles of the CBL-CIPK networking system	05 Nov 2018	1.5
► Writing or rewriting a project proposal CBL-CIPK pathways in the drought and salt stress response of <i>Solanaceae</i> : The role of CBL5	13 Jan 2020	6.0
► Writing a review or book chapter Mao J. <i>et al.</i> The CBL-CIPK network is involved in the physiological crosstalk between plant growth and stress adaptation.	13 Jul 2022	6.0
► MSc courses Plant Breeding (PBR-22303)	Sep 2018	3.0
Subtotal Start-Up Phase		16.5

2) Scientific Exposure	<u>date</u>	<u>GP</u>
► EPS PhD days Annual EPS PhD Days 'Get2Gether 2019', Soest (NL) Annual EPS PhD Days 'Get2Gether 2023', Soest (NL)	11-12 Feb 2019 1-2 May 2023	0.6 0.6

TOTAL NUMBER OF CREDIT POINTS*	38.7
---------------------------------------	-------------

Herewith the Graduate School declares that the PhD candidate has complied with the educational requirements set by the Educational Committee of EPS with a minimum

* A credit represents a normative study load of 28 hours of study.

Acknowledgments of Financial Support

The author is from the PhD Education Programs between the Graduate School of CAAS and WUR. The research described in this thesis was financially supported by the National Natural Science Foundation of China, the Fundamental Research Funds for China Agricultural Academy of Sciences, the International Foundation of Tobacco Research Institute of CAAS, the Agricultural Science and Technology Innovation Program, the Key Funding of CNTC and YNTI, the China Scholarships Council, and the International Exchange Scholarship of the GSCAAS.

Financial support from Wageningen University & Research for printing this thesis is gratefully acknowledged.
